A "VICTIM" writes to the *Manchester Guardian* to complain of the diseased state of certain "very fine mackerel which are being sold in that town," and he says that two out of three of the purchased fish were "covered with hair worms or trichinæ, coiled up just under the outer skin in small rings, enveloped as it were in a small capsule." He then goes on to say that these parasites when "embedded in the body cause intense pain and very serious danger." In view of lessening the constant alarm which announcements of this kind occasion, we beg to inform our readers that the parasites in question are little nematoids, well known to helminthologists under the names of *Agamonema capsularia* and *A. papilligerum*. They are sexually immature worms awaiting their final destiny within the body of some larger fish. The human frame is not the ultimate bearer of these parasites, and therefore it matters little whether the mackerel be eaten well cooked or otherwise. More than a dozen species of entozoa plague the unfortunate mackerel, but none of them are dangerous to man.

VACCINATION IN JAPAN.

THE medical men despatched last year from the Ozaka Hospital to Riukiu are (says the *Japan Weekly Mail*) likely to be in much request among the islanders. Measures are about to be taken for performing vaccination on a large scale, and, small-pox having always been regarded with great horror by the people, they are quite ready to fall in with the proposal. The disease has hitherto been looked upon as a judgment from heaven; if one member of a family fell ill with the malady the whole household was shunned, and the victim, from want of medical care and treatment, invariably died. Isolation appears to have been rigidly enforced in the case of infected districts, and this measure has kept the disease in abeyance; but prophylaxis commends itself to the thinking part of the population, and the Ozaka surgeons will probably have a busy time from the commencement of next month, when vaccination will be inaugurated.

FRACTURED SKULL IN AN INFANT.

THE difficulty of diagnosing a fractured skull in an infant is well known, and the necessity of being aware of its possibility in a case of accident, even when there are no marked symptoms, is brought strikingly before the profession in the case which has occupied so prominent a place in the papers during the past week. An infant, aged two years, was run over on the 1st inst., and was taken to the Seamen's Hospital, Greenwich. The child was kept in the hospital until the 5th inst., and showed no symptoms whatever. There were no convulsions, vomiting, coma, or partial paralyses—indeed, except the bruises, there was no indication of anything serious having taken place, and so the child was discharged on the non-appearance of anything that would warrant its detention. The mother, on its discharge, was urged to have medical superintendence, so that if anything untoward should occur, prompt action should be taken. Two days after the discharge from the Seamen's Hospital it was removed to the East London Children Hospital at

Shadwell, where it died on the next day. On post-mortem examination a fractured skull was found to be the cause of death. At the inquest it was attempted to be shown that the child was improperly discharged from the Seamen's Hospital, and that the sister of the ward was to blame, but the evidence at once cleared her from any such interference with treatment of the case. Mr. Johnson Smith, the resident surgeon, had ordered the removal of the child because there had been scarlet fever recently in the hospital, and because the child had shown no symptoms except from the bruises. In so doing he acted quite properly and in accordance with the instructions of the Hospital authorities—viz., to detain cases of emergency (not being sailors), until the urgent symptoms have passed off. Some of the comments on the case which have appeared would seem to have been written in complete ignorance of the elementary surgical principle that a fractured skull does not necessarily betray its existence by giving rise to marked symptoms.

THE LONDON FEVER HOSPITAL.

THIS admirable institution is living on its capital, and unless an unusual sense of its claims takes possession of the public very quickly there is a fear that it will have to be closed or greatly curtailed in its usefulness. The subscriptions amount only to £699 per annum, and, at the present rate of expenditure, the funds will hold out only two years more. We know no hospital more worthy of public support than this. Last year there were under treatment in it 1012 patients, most of them cases of scarlet fever. When it is remembered that this hospital has every provision and accommodation for the treatment of patients themselves, and that by taking them in the remaining members of the household would probably be saved from infection, the claim of the charity upon the benevolent public will be seen to be strong, indeed—a claim which is not lessened by the fact that the hospital is now devoted to the care of those who can pay more or less towards their maintenance.

THE CORONERSHIP FOR CENTRAL MIDDLESEX.

DR. DANFORD THOMAS, the Deputy of the late Dr. Hardwicke, is now the only medical candidate in the field for the vacant coronership of Central Middlesex. As such he is entitled to, and has an irresistible claim upon, the support of the profession. The question at issue is one of principle, and Dr. Danford Thomas may be trusted to discharge loyally and efficiently the duties of the office for which he is a candidate.

DRUNK OR DYING?

ANOTHER lamentable case has occurred to warn medical men of the difficulty of deciding the exact nature of cases of insensibility brought suddenly under their notice. The case in question was the subject of an inquest before Mr. Humphreys. It was that of a young woman picked up insensible in the City-road last week. She was carried about from place to place in a way that is not pleasant to think of. First she was taken to Dr. Powell's house, who very naturally sent her to St. Bartholomew's Hospital. Here, after the use of the stomach-pump, and having so far recovered as to "answer questions incoherently," she was remitted to the care of the police at the Station for six hours. Thereafter she was sent to the Holborn Infirmary, City-road, where she died. Dr. Yarrow, at a post-mortem, found the cause of death to be extravasation of blood. There is a difference of opinion as to whether alcohol had anything to do with her condition. Dr. Powell, in a letter to the *Daily Telegraph*, says that she did not smell of alcohol, and sent a very careful message to the hospital by the police, expressing his opinion that the case was one of injury to the brain, and not of drink. Under all the circumstances, we regret that the patient was not detained at the hospital. As errors of diagnosis are so easy, and yet of such grave consequence, it surely would be a safe rule to keep doubtful cases at least twelve hours under observation, if not longer. The jury returned a verdict of "Accidental death."

THE VICTORIA UNIVERSITY.

THE new northern university has decided to grant degrees in Science without requiring from the graduates any knowledge of Greek or Latin. Even the graduates in Arts are only expected to satisfy the examiner in Latin and Greek at the preliminary examination. Whether the neglect of the classics in favour of more "useful" subjects is likely to be of permanent benefit to the interests of education or not may be a moot question, but there can scarcely be any doubt that no place is more appropriate for testing modern ideas of the nature of education than a modern university. If the accumulation of knowledge be the end and aim of education, no means to attain this object is more suitable than that offered by a brand-new university in a thriving commercial city. The older seats of learning at Oxford and Cambridge are too closely attached to their traditions to be trusted to identify themselves at once and for ever with the utilitarian theory of education. The future alone can show whether a man will be a better physician, or chemist, or engineer, or mathematician, when he has had no other training than that obtained by the study of his own special branch of science, and knows nothing that lies outside that narrow region.

THE APPOINTMENT OF MEDICAL OFFICER OF HEALTH FOR HASTINGS.

THE following memorial is, we are informed, being numerously and influentially signed for presentation to the Mayor of Hastings:—

"We, the undersigned inhabitants of the borough, do respectfully ask you to convene at your earliest convenience a public meeting, to protest emphatically against the late appointment of Medical Officer of Health against the general wish of the inhabitants, and which we consider calculated to do infinite damage to the trade and prosperity of the town by bringing disrepute upon it as a health resort, which is assuredly evinced by strictures passed in the leading medical journals, and is thus brought under the notice of the profession, who will assuredly refrain from recommending their patients to come here if such appointment be maintained."

CLOSING THE FULHAM SMALL-POX AND FEVER HOSPITALS.

THE Association for closing the Fulham Small-pox and Fever Hospitals is making head-way in an assault on the institution alleged to be injurious to the immediate neighbourhood. A large and influential committee has been formed, and guarantees and subscriptions have been received to an amount enabling the enterprise to be carried out in its entirety.

THE question of Hospital Reform is agitating the minds of the medical community at Melbourne. The *Australian Medical Journal* says the first urgent necessity is the appointment of a senior resident surgeon in the hospital of that city, in whom should be vested the powers in connexion with the internal administration of the charity now exercised by the secretary. Our contemporary declares that the statistics at present furnished are utterly worthless, and that many other matters of no slight importance require alteration to make the working of the institution satisfactory.

THE medical depôt at Allahabad, under the charge of Surgeon-Major J. B. S. Brown, medical storekeeper, was completely burned to the ground on the 2nd April; only the quinine and opium were saved. The fire broke out at 2 P.M. in a room containing ether and acids. The loss to Government is estimated at £30,000. This important depôt, which supplies the whole of the North-West Provinces and Oude, had only recently been removed from the fort to an old thatched and tiled barrack far away from the present cantonments, but near the old cantonments now occupied by a native cavalry regiment.

THE first examination this year of candidates for medical diplomas in Japan was brought to a conclusion in Tokiyo on the 3rd instant. The number of applicants was seventy, of whom thirty withdrew in the early stages of the trial, and of the remaining forty, not more than half are believed to have been successful.

THE Introductory Lecture to the Course on Public Health at University College will be delivered by Professor Corfield on Tuesday next, May 2nd, at 4 P.M., and the course will be continued on succeeding Thursdays and Tuesdays at the same hour.

THE death is announced of Dr. Richard Oswald Cowling, Professor of the Principles and Practice of Surgery in the University of Louisville.

THE Harveian Lectures this year will be given by Dr Alfred Meadows. The subject will be "On Menstruation and its Derangements."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Erith (*Urban*).—Mr. Fredk. B. Jessett's report for this district for the past year shows that the sanitary authority has not been entirely inactive, and that "they are considering even an elaborate and thoroughly exhaustive plan" for draining the whole parish, but that this question has not yet passed beyond the stage of consideration. Nevertheless we learn that in this charmingly situated locality "the privies are as bad as ever," and that one foul ditch, at least, and a stinking open cesspool, may be permitted to exist without apparently disturbing the equanimity of the sanitary authority. In one respect, however, the sanitary authority is setting an excellent example to the several river-side sanitary authorities which exist on both banks of the river from Bow Creek to Gravesend. Mr. Jessett reports that the local board has been taking very active measures to abate the nuisance arising from the different factories along the river, and with a result that ought to encourage even more active efforts, and induce the other river-side sanitary authorities to join with them. The offensive trades which have been driven out of the metropolis—the artificial manure makers, workers of various kinds in tallow, glue and varnish manufacturers, &c.—have taken up their abodes in the long line of marshy districts situated on both banks of the Thames below Bow Creek. There wholly uncontrolled they have been suffered to settle, and have reproduced and are reproducing in the most reckless manner the nuisances which rendered their presence in the metropolis intolerable. The sail along the Thames to and from Greenwich, which only a few years ago was one of the greatest enjoyments to the Londoner, is gradually becoming, from the offensive trades practised and increasing on the banks of the river, one of the most unpleasant experiences in stinks and smoke which can be conceived, and this wholly from the neglect of the local authorities. Self-interest, in view of the slowly approaching destruction (if this be not stayed) of the residential value of the higher grounds bordering the Thames on this part of its course, it might have been thought would have induced earlier protective action on the part of the river-side authorities. But no; hence the action of Erith is all the more welcome. The death-rate of Erith in 1880 was 14·64 per 1000 of the population.

Doncaster (*Urban*).—Estimated population, 1880, 22,000; birth-rate 34·5 per 1000 inhabitants; death-rate 24·8 per 1000. Mr. J. B. Withington gives great attention to the death-rate among infants and young children in the district, "more than half" of the deaths recorded in 1880 having been among children under five years of age. This "startling fact," as he justly phrases it, calls for the most earnest consideration of the sanitary authority, and Mr. Withington devotes the main portion of his report to discussing it. Of the large proportion of deaths among infants assigned to wasting diseases and diarrhœa, he observes: "The extreme fatality from these two classes of disorders points very strongly to want of proper feeding and attention during infancy, a general experience being that mothers of the poorer class very commonly give their young infants solid or otherwise improper foods, whereas it is an established rule that, generally speaking, nothing beyond the nourishment afforded by nature should be given for the first three or six months; and improper feeding is a most frequent cause of diarrhœa and wasting." Doncaster has just completed a system of new water-works for the supply of the population, but this important town does not appear to possess any hospital accommodation for infectious diseases.

Newton Abbot (*Rural*), *and Walborough and Dawlish* (*Urban*) *Combined Sanitary Districts.*—Mr. Leonard Armstrong's reports for 1880 for these combined districts are full of interest as showing their condition during a period when the presence of fatal epidemic disease among children disturbs the even current of sanitary administration. Newton Abbot, with an estimated population of 25,619, had a birth-rate of 29·4 per 1000 inhabitants, and a death-rate of 18·42. Measles and whooping-cough troubled the year, and diarrhœa, which had been little fatal in 1879, again became prominent in the mortality of 1880. Writing of the diarrhœa, Mr. Armstrong says: "This increase is due to the higher temperatures of the year. Warmth by itself does not, probably, produce sickness, but acting on inorganic matter in and about our dwellings, it promotes decomposition, and fills the atmosphere with unhealthy exhalations that envelop, as in a fog, the houses and inmates of ill-ventilated localities. Children get fatal diarrhœa from breathing these unwholesome exhalations, and fever is, I believe, the consequence in some of older growth."

Bisley, Urban (*Gloucestershire*).—Dr. Partridge reports for this district during 1880 a birth-rate of 30·3, and a death-rate of 18·2, per 1000 of the inhabitants on an estimated population of 5273. He comments on the high infantile mortality, and confesses to the difficulty he experiences in tracing the swollen rate to its true origin; but he expresses the opinion that to some extent he has reason to believe that it arises from bad nursing and dietary.

THE SMALL-POX HOSPITAL DEADLOCK IN THE METROPOLIS.

Instances of the evil consequences of the present stop put to the increase of hospital accommodation for small-pox cases in the metropolis are beginning to multiply, and it will be well if we have not to learn from experience that there may be worse evils than those which have already arisen from the incidental augmentation of small-pox cases about existing hospitals. We learn from various parts of the metropolis that the present hospital accommodation for small-pox is exhausted, and that patients are accumulating in their own dwellings without any check upon the spread of the disease among their neighbours or other occupants of rooms in the same house. This state of matters is apt to have far-reaching consequences when the family affected is engaged in tailoring, or as seamstresses, or in laundry work. More than one instance of laundry work being carried on in houses in which one or more cases of small-pox existed have been brought to our knowledge. Some feeble efforts are being made by the local sanitary or Poor-law authorities to supplement the hospital accommodation of the Asylums Board, and we learn with pleasure that there is a likelihood of the Poplar Sanitary Hospital being now brought into use for districts in the east of London.

INFECTIOUS DISEASES.

A deputation from several societies concerned in promoting public health waited upon the President of the Local Government Board on Tuesday last, to urge the desirability of securing the public notification of infectious diseases, and the provision of more efficient means of isolating persons suffering under such diseases. The deputation was introduced by Mr. Hastings, M.P., and Dr. Farquharson, M.P. Mr. Dodson, after listening to the arguments of various members of the deputation, expressed his sense of the importance of the subjects brought forward, but referred to certain difficulties in the way of carrying out the suggestions advanced, and reminded the speakers that the sanitary authorities throughout the country had power to provide hospitals, though it had not been exercised to any large extent. In answer to a question by the right honourable gentleman as to the comparative danger of concentrating patients in a few centres, or distributing them in a large number of small districts, Mr. Dudfield said a district like Croydon, for instance, should have a hospital to itself; but it would be absolutely dangerous to have a separate hospital in the forty different districts of the metropolis.

PUBLIC HEALTH MATTERS IN KENSINGTON.

Dr. Orme Dudfield's report on the health of Kensington for the four weeks ending March 26th is, perhaps, not so much of interest as concerns the district to which it specially refers, as from the incidental matters it deals with affecting the metropolis at large; not that it does not contain matter even as regards the Kensington district which deserves careful perusal, particularly in reference to the spread of small-pox by unrecognised and modified cases of disease. The cases related by Dr. Dudfield of this sort and of the mischief arising therefrom are of considerable value; but to persons living outside the limits of Kensington the interest of the report will chiefly consist in the observations made on the Hampstead Hospital Case, the action of the Fulham District Board of Works with reference to the Fulham Small-pox Hospital, on the desirability of local hospitals, the action of the Kensington Vestry with reference to the question of the compulsory notification of infectious diseases in the metropolis, &c. On these several subjects Dr. Dudfield conveys information which we are glad to have in an authoritative and readily accessible form.

A notice has been given for discussion at the Fulham Board of Guardians "that it be a suggestion from this Board to the Local Government Board that it is desirable to provide accommodation for small-pox patients in hulks on the river at its broadest part below Erith with all requisite arrangements as to disinfectants, and for kindly removal of patients, with the object of providing perfect hospital accommodation and avoiding the alarm in populous districts of hospitals being placed in their midst." It is curious how the practically insuperable difficulties of placing infectious disease hospital-ships along the course of a great highway should have escaped the attention of the proposer of this suggestion.

Colonel Bolton's report, as water examiner, of the water supplied by the Metropolitan Companies in March shows that the water in the Thames was good in quality from the 1st to the 4th of March, when it became bad and continued so until the end of the month. The water in the River Lea was generally good throughout the month. As a rule the water delivered was efficiently filtered, the Chelsea and Grand Junction Companies alone, according to Dr. Frankland, failing in this matter.

In consequence of the increase of small-pox in the City, Dr. Sedgwick Saunders has thought it desirable to suggest the provision of additional hospital accommodation. A member of the Commission at a recent meeting suggested the use of the port-hospital ship at Gravesend, and was surprised to find that this ship was not even used for cases of small-pox occurring in the Pool. It seems to us that the suggestion was impracticable.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a slight decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 4986 births and 3211 deaths were registered last week. The births were 200, and the deaths 40, below the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had slowly but steadily increased from 20·6 to 22·9 per 1000 in the five preceding weeks, declined last week to 22·0. The lowest rates in the twenty towns last week were 17·2 in Portsmouth, 17·5 in Norwich, 17·7 in Salford, and 17·9 in Bradford. The rates in the other towns ranged upwards to 25·8 in Wolverhampton, 27·3 in Liverpool, 28·3 in Plymouth, and 29·9 in Newcastle-upon-Tyne. During the first three weeks of the current quarter the death-rate in the twenty towns averaged only 22·4 per 1000, against 25·0, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 315, 339, and 410 in the three preceding weeks, declined to 382 last week; these included 85 from small-pox, 84 from whooping-cough, 71 from measles, 63 from scarlet fever, 22 from diphtheria, and 31 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged 2·6 per 1000 in the twenty towns, and ranged from 0·4 and 0·8 in Hull and Bradford, to 3·1 and 3·8 in Newcastle-upon-Tyne and Portsmouth. The general fatality of measles, scarlet fever, and whooping-cough was considerably below the average for the season. The 22 deaths referred to diphtheria in the twenty towns exceeded the numbers in recent weeks, and included 10 in London, 7 in Portsmouth, and 2 in Plymouth; this disease has been more or less fatally prevalent in Portsmouth for some months, but the fatal cases last week considerably exceeded any recent weekly number. The highest death-rates from fever occurred last week in Portsmouth and Bristol. Small-pox caused 88 more deaths in London and in its outer ring of suburban districts, and one in Liverpool; no fatal case was, however, recorded in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased from 820 to 940 in the three preceding weeks, further rose to 963 on Saturday last; the number of new cases admitted to these hospitals last week was 227, against 224 and 244 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had slowly increased from 345 to 395 in the five preceding weeks, declined to 338 last week, and were 38 below the corrected average number in the corresponding week of the last ten years; they included 211 from bronchitis and 89 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 4·7 per 1000 in London last week. The rate from the same disease was no less than 8·8 in Liverpool.

The causes of 80, or 2·5 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 0·9 per cent. in London, whereas it averaged 4·0 per cent. in the nineteen provincial towns. No uncertified deaths were recorded last week in Brighton, Portsmouth, Norwich, Leicester, or Nottingham; whereas the proportions of such deaths were largest in Sheffield, Salford, Bradford, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half persons, the annual death-rate last week was equal to 20·9 per 1000, showing a further decline from the rates 23·5 and 22·1 that prevailed in the two preceding weeks; this rate was 1·1 below the average rate in the twenty English towns. The rates in the eight Scotch towns ranged from 12·1 and 14·6 in Leith and Greenock, to 23·7 and 29·2 in Aberdeen and Perth. The deaths referred to the principal zymotic diseases in the eight towns, which had been 82 and 69 in the two preceding weeks, rose last week to 84; they included 24 from whooping-cough, 15 from scarlet fever, 15 from measles, 12 from diarrhœa, 11 from "fever," 7 from diphtheria, and not one from small-pox. The annual death-rate from these zymotic diseases averaged 3·3 per 1000 in the eight towns, which was 0·7 above the average rate from the same diseases in the twenty English towns. This zymotic death-rate in the eight Scotch towns ranged from 0·6 and 1·0 in Greenock and Dundee to 4·9 and 5·8 in Edinburgh and Perth. The 24 fatal cases of whooping cough corresponded with the number in the previous week, and included 10 both in Glasgow and Edinburgh. The deaths from scarlet fever, which had been 6 and 10 in the two previous weeks, further rose to 15 last week, of which 9 occurred in Edinburgh, 3 in Glasgow, and 2 in Leith. The 15 deaths from measles also showed a considerable increase upon recent weekly numbers; of these 13 were recorded in Glasgow and 2 in Aberdeen. Nine of the 12 deaths from diarrhœa were returned in Glasgow. The 11 deaths referred to "fever" (typhus, enteric or typhoid, and simple continued) showed an increase of 4 upon those in the previous week, and included 6 in Glasgow and 2 in Aberdeen; the annual death-rate from this cause considerably exceeded that which prevailed in the twenty English towns during the week. The 7 deaths from diphtheria showed a decline from the numbers in recent weeks; 3 occurred in Edinburgh and 2 in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 163 and 144 in the two preceding weeks, further declined to 135 last week, and were equal to an annual rate of 5·3 per 1000, against 4·3 from the same diseases in London. The greatest proportional fatality from lung diseases in the Scotch towns occurred last week in Glasgow, Aberdeen, and Paisley.

HEALTH OF DUBLIN.

The rate of mortality in Dublin increased again last week. The annual death-rate in the city, which had pretty steadily declined in the twelve preceding weeks from 47·4 to 29·0, rose again last week to 32·6. During the first three weeks of the current quarter the death-rate in the city averaged 30·8 per 1000, against 22·4 in London and 21·5 in Edinburgh. The 208 deaths in Dublin last week showed an increase of 23 upon the number in the previous week; they included, however, 9, or little more than 4 per cent., which were referred to the principal zymotic diseases, against numbers declining from 19 to 12 in the four preceding weeks. These 9 deaths from zymotic diseases included 4 from whooping-cough, 2 from fever (typhus, enteric or typhoid, and simple continued), 2 from scarlet fever, 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. The annual death-rate from these zymotic diseases did not exceed 1·4 per 1000 in Dublin last week; whereas it was equal to 3·5 in London and to 4·9 in Edinburgh. The deaths referred to fever in Dublin, which had been 8 and 7 in the two previous weeks, further declined to 2 last week, and were fewer than in any week for many months; the annual death-rate from this cause in Dublin last week was only slightly in excess of the average rate in the twenty English towns. The 4 deaths from whooping-cough in Dublin exceeded the numbers in recent weeks, while the fatal cases of other zymotic diseases were again remarkably few. The deaths of infants were more numerous last week, whereas those of elderly persons showed a further decline from recent weekly numbers.

VITAL STATISTICS OF MELBOURNE IN 1880.

Mr. H. H. Hayter, the Government Statist of Victoria, has just published an analysis of the vital statistics of Melbourne for the year 1880. The population of the Statistical District of Melbourne and Suburbs, embracing a radius of ten miles, was estimated at 270,264 persons in the middle of 1880. The birth-rate in the city was equal to 32 per 1000 persons living, and was considerably lower than in any year of the preceding decade; the mean birth-rate in the ten years 1870–79 was 34·3 per 1000. The recorded deaths were equal to a rate of 19·2 per 1000, corresponding with the rate in 1879, but 1·3 below the mean rate in the ten years 1870–79. The deaths of children under five years of age were equal to 40 per cent. of the total mortality in the city, differing but slightly from the proportion prevailing in recent years. The 2088 deaths of children under five years of age included 1439 infants who had not completed their first year of age; these showed a rate of infant mortality equal to 166 per 1000 births recorded. Compared with the low gross death-rate, the rate of infant mortality in Melbourne showed a marked excess during 1880. Rather more than 9 per cent. of the deaths were of persons aged upwards of sixty years; this proportion, however, was considerably below that which usually prevails in English towns. The deaths referred to zymotic diseases in Melbourne and suburbs during the year were 1062 or 20·5 per cent. of the deaths from all causes; these included 174 from measles, 138 from enteric fever, 55 from whooping-cough, and 370 from diarrhœal diseases. These zymotic deaths showed a decline of 104 from the number in the preceding year. Measles, however, appeared in an epidemic form for the first time since 1875. It caused, however, only 174 deaths, whereas it caused 508 deaths in 1875. Typhoid fever was less fatal than it had been for many years, and the 138 fatal cases were fewer by 57 than the number in 1879. Puerperal mortality caused 45 deaths, of which 3 resulted from childbed fever; these gave a proportion of 5 deaths of mothers to each 1000 infants born alive, which differs but slightly from the average proportion in England and Wales. The high rate of infant mortality, and the comparatively large proportion of deaths from zymotic diseases, suggest that the true gross death-rate must be higher than that reported by Mr. Hayter. This return, however, does not afford the means for surmising whether this under-statement of the death-rate is due to incomplete registration, or to an over-estimate of the population of the city. It is beyond question that the mortality statistics of Melbourne for 1880 afford abundant evidence that the sanitary condition of the city is not so satisfactory as would be indicated by a gross death-rate of 19·2 per 1000.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE ISLEWORTH SEWER-BROOK.

The Thames Valley sewerage question in its broad aspect is still we fear as far from solution as ever, and the sooner therefore the different localities along the river-bank begin to look after their own interests the more likely they will be to escape those epidemics which are inevitably in store for those who neglect the first laws of health. By the side of the Station-road at Isleworth there runs what might be called a brook, but which is really nothing but an abominable stinking open sewer, which carries the sewage of Spring-grove and part of Hounslow to the much suffering Thames. That in a district where every house has its garden, and where market-gardens are measured by the thousand acres, such valuable matter should be allowed to work mischief instead of good is to us a mystery. We believe an action has already been brought by a public-spirited inhabitant against the local Board to compel them to abate or abolish the nuisance; but such action was unsuccessful, and indeed it seems to us a very difficult matter for a Board to deal with. It is a matter which concerns individuals rather than Boards. No man by the present law of England is allowed to pollute a river, and we should advise that, instead of bringing an action against a "Board," actions should be brought against the individuals who pollute the stream. Let the public-spirited parishioner who brought the previous action bring another against his neighbour on the banks of the sewer-brook, and compel him to dispose of his sewage either upon his own garden or the gardens of the market-gardeners. One successful action would carry the rest; the individuals would recoup by their increased garden produce what they expend in alterations, and the district would be saved a high "rate" to pay for some sewerage scheme, the success of which must necessarily be a matter of doubt.

THE ABERDEEN EPIDEMIC.

The outbreak from diseased milk has now subsided, no new cases having been reported, and most of those who were attacked having recovered. A public inquiry into the cause and nature of the outbreak has been ordered by the Board of Supervision, and a commission consisting of A. Rutherford, Advocate, and Dr. Littlejohn, Edinburgh, began its sittings on Monday, with the view of obtaining all the evidence available to facilitate the inquiry.

The Factories Act, 1881, recently promulgated in India, prohibits the employment of children in factories other than indigo and tea and coffee factories under seven years of age, and provides for the regulation of the employment of children employed in factories between the ages of seven years and twelve, as also for the due inspection of factories.

The National Health Society has arranged for the delivery of a series of drawing-room lectures at 23, Hertford-street, Mayfair (the residence of Chas. Matthews, Esq.), on every Friday until and including May 27th. Among the lecturers are Dr. Robert Farquharson, M.P., Mr. C. N. Cresswell, Mr. Henry Power, and others. Communications should be addressed to Miss Lankester, the Secretary, at the Society's Offices, 44, Berners-street, Oxford-street.

THE SERVICES.

THE TRANSVAAL WAR.

Papers and letters by the last Cape mail supply us with some details of information which will be read with interest by the many friends of our medical officers at the front. The base hospital of the Transvaal Field Force at Fort Amiel, Newcastle, consists of thirteen huts and two marquees. Each hut holds twelve patients. The hospital accommodation was also temporarily increased by utilising some ordnance store-sheds for the heavy and unexpected influx of wounded after the battles of Ingogo and Majuba Hill. Altogether provision was made by Mr. Holloway, the Principal Medical Officer, for over three hundred sick. Surgeon-Major J. A. Scott, M.D., has assumed the duties of senior medical officer, Transvaal Field Force, vice Surgeon-Major T. Babington, who remains in charge of the field hospital, Mount Prospect. Mrs. Hawthorne, wife of Colonel Hawthorne, R.E., Miss Williams, three sisters from Bloemfontein, with a staff of trained orderlies of the Army Hospital Corps, are detailed for nursing duty under Surgeon-Major Stokes, the medical officer in charge. Many of the wounded are described as being very serious cases: one man was riddled with eleven bullets; but owing to a good climate, skilled nursing, with ample supply of medical comforts, food, &c., the mortality has been very slight, and the wounded are reported doing well. Milk is brought to the hospital daily from a farm in the neighbourhood. The ladies of Newcastle have been most kind in sending jellies, pillows, easy chairs, papers, and books for the invalids.

The Bearer Company was inspected by Deputy Surgeon-General Holloway on Feb. 28th at Pietermaritzburg, previously to its marching for the front. Convoys of sick and wounded able to travel are ordered to proceed from Newcastle and the frontier posts towards Durban, so as to relieve the field hospitals. Rest camps have been formed at Ingegane, Pilgrim's Rest, Sunday River, Colenso, Est Court, Moore River, Carey's Fort, and Howick. At Ladysmith a field hospital complete for thirty beds has been established under a medical officer. The trained nurses sent out from Netley arrived at Cape Town in the *Warwick Castle* on Feb. 28th, and proceeded at once to Durban *en route* to Newcastle.

Deputy Surgeon-Generals C. D. Madden, M.D., and J. Hanbury, C.B., are on passage home from India.

Brigade Surgeon Ekin has obtained leave of absence from India on medical certificate.

Surgeon-Major F. B. Scott, M.D., has been ordered to Dover for duty in the South-Eastern District on return from the Cape.

War Office.—1st Life Guards: Surgeon Seton Guthrie Hamilton, from the Army Medical Department, to be Surgeon, vice T. W. Thompson, resigned.—Grenadier Guards: Surgeon Ernest Harrold Fenn, from the Army Medical Department, to be Surgeon, vice W. H. Pickford, promoted into the Scots Guards.—Scots Guards: Surgeon William H. Pickford, M.B., from the Grenadier Guards, to be Surgeon-Major, vice F. Robinson, M.D., retired.

Army Medical Department.—Surgeon-Major Henry Hummerston Burford has been placed on temporary half-pay on account of ill health; Surgeon Albert Kirwan to be Surgeon-Major; Surgeon Francis George Adye-Curran, M.B., to be Surgeon-Major.

Admiralty.—In accordance with the provisions of Her Majesty's Order in Council of 1st April, 1881, Fleet-Surgeon John Caldwell has been placed on the Retired List, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets. Fleet-Surgeon John Frederick Mitchell has been placed on the Retired List of his rank from the 18th inst. Fleet-Surgeon Leonard Lucas has been placed on the Retired List from the 18th inst., with permission to assume the rank and title of Retired Deputy Inspector-General of Hospitals and Fleets from the same date. Surgeon Matthew Fletcher Ryan has been promoted to the rank of Staff-Surgeon in Her Majesty's Fleet, with seniority of 1st inst.

The following appointments have been made:—Henry Mark Scott to be surgeon and agent at Enniscrone, vice MacMann; Robert Roberts to be surgeon and agent at Portmadoc (new appointment); Staff-Surgeon A. G. Colquhoun to the *Iris*, vice Johnson; Staff-Surgeon T. D. A Bromlow, M.D., to the *Pembroke*, vice Colquhoun.

DR. KIDD'S "LAWS OF THERAPEUTICS."

As Dr. Kidd has not replied to our queries appended to his letter of the 16th inst., and as there is some little doubt in the minds of the medical profession as to the exact attitude assumed towards it by Dr. Kidd, we think it advisable to print a few extracts from the second edition of his book on "The Laws of Therapeutics," published in 1881. In Chapter I. we find—

"I have endeavoured to forget men and their systems, and to search for truth—for all truth. The true student of nature ever delights to lay self aside, to present his offering to the growth of knowledge and withdraw.......The physician should endeavour to ascertain if the good providence of God has ordained exact laws for the selection of curative agents in the treatment of disease. If such laws exist, how solemn the position of those who would reject them! The most pressing question at the present time for the physician is whether the treatment of disease is to depend on mere opinion which varies with each doctor, and perishes with the individual, or on laws which, founded on the immutable truth of facts, can never perish, but must endure through all ages?......The practice of physicians thirty years ago is at present regarded as worse than useless. If law had governed their practice, the truth in that practice would have remained as the inheritance of science, available for their successors—truth can never perish."

Of Hahnemann he says, "It then occurred to him that *the reason why cinchona cures ague* is because of the power inherent in it to *produce symptoms* in a healthy person similar to those of ague. From this the system of homœopathy became gradually evolved, after many years of patient labour in proving upon his own person the qualities or actions of various medicines. Gradually also he began to lessen the amount of dose, not by any logical deduction from facts, but rather from an arbitrary conceit of his own fancy, till he broached the mystical doctrine of infinitesimal doses and of dynamisation" (p. 29)......."Truth is greater than Hahnemann, and of late years his speculations about psora and infinitesimal doses have been tacitly given up by all the most skilful and intelligent of his followers.......Twenty-seven years ago I saw that the essential truth of Hahnemann's law was totally independent of his speculations about dynamisation. Adopting with great delight the law of *similia similibus curantur* as the chief though not the only foundation for therapeutics, I learnt for myself that Hahnemann 'sober,' teaching the use of the pure undiluted tinctures, was a far better guide to heal the sick than Hahnemann 'drunk,' with mysticism calling for the exclusive use of infinitesimal doses. The latter I gradually cast aside *in toto* as untrustworthy and unjust to the sick, whose diseases too often remained stationary under treatment by globules, but were most effectually and quickly cured by tangible doses of the same medicines which failed to cure when given in infinitesimal doses."

The law of "*similia similibus curantur*" being "the chief though not the only" law of therapeutics, what, it will be asked, are the other laws which are to guide us in the treatment of disease? On p. 94 we find:—"Looking to the observations of facts, apart from the theoretic speculations, two primary laws of therapeutics unfold themselves. As Galvani and Faraday have afforded names for Galvanism and Faradism, those two laws of therapeutics may well be called Galen's law, or the antipathic founded upon the rule of *contraria contrariis*, and Hahnemann's, or the homœopathic law, founded upon the relationship of similars." Again, at p. 121:—"Rejoicing to enlarge the boundaries of knowledge, true science cannot ignore any law, though its sphere of action be limited and not of universal application. Galen's law of *contraria contrariis* has its place, and a very prominent place, still in the practice of every physician."

We are ready to admit that, to the superficial observer, it may sometimes appear that diseases are cured by drugs which produce symptoms similar to the disease. For example, a glass of brandy will sometimes steady a tremulous hand. Again, diseases are sometimes cured by drugs which produce opposite symptoms. These stray facts, however, are quite distinct from laws, and we cannot understand how any man can be found to give the name of exact laws to a few scattered facts which, if they are to be regarded as "laws," are evidently mutually destructive. When Newton stated that "*masses attract each other with a force which varies according to the inverse square of the distance*," he enunciated a "law," but Dr. Kidd's "Laws of Therapeutics" have clearly no claim to be placed in the same category.

The closest resemblance which exists between the effect of a disease and the effect of a drug is to be found between tetanus and the action of strychnia, and it is natural to turn to these instances to see whether Dr. Kidd has succeeded in curing many cases of tetanus by adhering to those laws which have, according to him, been ordained "by the good providence of God." At p. 106 it is stated that "it would be justifiable, I conceive, to give the strychnia in the hope that it might occasion a morbid action which would supersede the morbid action of the disease [tetanus], and yet be less perilous and more manageable than it. This, were it successful, would be a cure according to the Hahnemannic doctrine—*similia similibus curantur*—a doctrine much older, however, than Hahnemann." This is a quotation from Sir Thomas Watson, and on p. 128 is another quotation from the same author. "Sir Thomas Watson, writing of the use of strychnia, says, 'If the dose be too large, a temporary aggravation of the disease may show itself for a time.'" These two quotations might lead the non-medical reader (and Dr. Kidd probably has many such) to think that Sir Thomas Watson advocates the use of strychnia in tetanus. A reference to the last edition of his classical work shows such not to be the case, but no reference to the exact source of the quotations is given.

On p. 127 we find "when the reflex irritability of the spine is increased, as in tetanus, a most minute dose of strychnia, $\frac{1}{200}$ of a grain, will increase that irritability and bring on muscular jerking." These are all the references we can find to the most exact parallel which is known to exist between a disease and the effects of a drug, and of these three references for only one is the author responsible, and this shows clearly that if the law of Hahnemann (and "how solemn the position of those who would reject it!") is to be followed, Hahnemann "drunk," as Dr. Kidd says, would be a far safer person at your bedside than Hahnemann "sober."

Let us leave this trifling exception to "law," and turn to Dr. Kidd's book for examples of the real good of following up the dogma of "*similia similibus.*" The prevention of small-pox by vaccination is claimed as an example of the law, and in 1850 Dr. Kidd cured an obstinate case of eczema in a child by revaccinating it, "the principle of *similia similibus* suggesting the remedy." "*Scores of vaccine vesicles* appeared all over the back, shoulders, arms, and chest" (p. 101), and the child got well. Now, eczema is, perhaps, the commonest of the chronic diseases of childhood, and Dr. Kidd must have had opportunities of curing thousands of other cases in the same way, unless he has incurred the solemn responsibility of upsetting his divine law. No other case is mentioned, however. On page 102 we find, "The action of diuretics is very closely allied to the process at work in certain diseases of the skin. The benefit to be derived from such is well illustrated by Dr. Tilbury Fox." In 1854 Dr. Kidd cured a lady of gall-stones by giving her ox gall (p. 103). On p. 104 a woman is mentioned who was cured of acidity and spasm by taking lemon-juice after meals. In 1869 a woman was cured of floodings and threatenings of miscarriage by four leeches over the right ovary. In 1850 a case of exophthalmic goitre was relieved by belladonna. In 1868 chronic cough, in a young lady, was cured by Fowler's solution, and in 1861 an irritable bladder was relieved by one drop of tincture of cantharides every four hours, and another man, with the very opposite symptoms of suppression of urine of four days' standing, was relieved in half an hour by the same means. A few cases such as this are clearly not sufficient to establish a law.

Dr. Kidd's attitude towards the rest of the profession is, to say the least, not friendly. On p. 14 we find: "To discourage drugging and substitute wise regulations of habits of life, is still an unpardonable sin to the orthodox practitioner." At p. 46 we find an allusion to "such exploded things as bleeding, leeching, blistering, and mercury," but on p. 74 we find that Dr. Kidd is acquainted with the action of mercury; on pp. 76 and 105 he recommends leeches to the temple and ovaries; on pp. 46 and 127 he speaks of the good effect of blisters in pericarditis. Physicians are often mentioned by name in this book; one is spoken of as overfeeding his patients in acute diseases, another is alluded to as having made more drunkards than any man living; Frazer, Crum-Brown, Brunton, and Ringer are spoken of as "afraid to teach the laws of fundamental principles which underlie the science of therapeutics." Some of our foreign brethren are strangely miscalled, thus: Czermak becomes on p. 52 Zermach, Binz, at p. 56, is apparently spoken of as Dr. Binns, Duchenne, at p. 196, is miscalled Duchesne, and at p. 123 there is a curious reference to "*Hanover Correspondence* Blatt."

On p. 81 there occurs the following paragraph: "How often do we see the energetic practitioner, unable to find the key, trying in vain to open the casket with smart blows of a hammer. On the other side stands the mild disciple of modern expectant medicine for months watching the casket, examining the lock, but unable to find the key, till to his horror the friends bring in a more dexterous operator. The cure of the disease soon speaks for the perfect workman. . . . . It is then that the *gift of healing* [the italics are our own], which the true physician derives from the knowledge of the principles or laws of cure, comes in to assist in extricating the patient from the tendency towards death and the destruction of organs."

And again (p. 229): "Doubtless there will always be a large field for empirical medicine; genius often overleaps the boundaries of science when the latter degenerates into routine or safe orthodoxy. When strict theorists and dogmatists give an uncertain sound, it needs a dash of empiricism to cast aside conflicting theories and arrive at truth by *insight*." (The italics are ours.)

Turning from theory to practice, and glancing at the *cases* which are scattered throughout the book, we fail to see that in his treatment of disease Dr. Kidd is at all careful to observe the laws which he lays down, or that the treatment, except in a few instances, materially differs from that pursued by other practitioners. It is true that the bulk of the profession have not found dilute nitric acid or hydrastis of much use in curing fistula in ano (of which Dr. Kidd gives two examples at pp. 174-5), nor has hydrastis canadensis in other hands than his proved of service in curing cancer (p. 237). Dr. Kidd does not, however, tell us whether his successful treatment of fistula and cancer is due to an adherence to Hahnemann's or Galen's law. The book is full of sneers at those whom the author styles "orthodox practitioners."

In a recent letter Dr. Kidd states that he is no homœopath, but that he is in the habit of making use of "homœopathic remedies." It is needless to say that there are no such things as "homœopathic remedies" recognised by the profession, which is ready to use for the benefit of the sick anything which may prove of service, no matter by whom suggested or discovered. There is no mention of "homœopathic remedies" in Dr. Kidd's book, and the majority of the medicines used in the cases quoted are such as have been known to many generations of practitioners, whether orthodox or heterodox. Although Dr. Kidd enunciates what he is pleased to call the "laws of therapeutics," a careful perusal of his book clearly shows that no such laws exist, and that in the treatment of disease, wherein Dr. Kidd strives, as he says, "to be a workman approved by my Master, and a servant fit to minister among the sick, the sorrowful, and the weak," he is a law to himself, and the rules which are followed are not those of Hahnemann or Galen—but merely of Kidd.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following is the Third Report, dated March 17th, 1881, of the Committee on the necessary arrangements for the institution of additional Examinations for the Diplomas of Member and Fellow of the College, and adopted by the

Council at the meeting held on the 13th inst., as we announced last week :—

1. That it is not at present desirable that examinations in chemistry, materia medica, medical botany, and pharmacy be instituted at the College.

2. That the extended examination in medicine, as proposed in the Second Report of the Committee, and approved by the Council on Jan. 13th last, do come into force from and after Jan. 1st, 1882.

3. That the four examiners in medicine be chosen from the Fellows of the Royal College of Physicians, and be elected at the quarterly council in July.

4. That the two examiners in midwifery be chosen either from the Fellows of the College or from the Fellows of the Royal College of Physicians, and be elected at the quarterly council in July.

5. That the examiners in medicine and in midwifery be elected by the Council after nomination by a committee.

6. That the examiners in medicine and in midwifery be paid for their services by a capitation fee, and that the amount of such fee be hereafter determined by the Council.

7. That it be referred to this committee to confer with the examiners in medicine and in midwifery, and, after discussion with them, to determine the nature and extent of the examinations in medicine and midwifery respectively.

8. That it be at the same time referred to this committee, after such conference with the examiners, to advise the Council as to the amount of the capitation fee to be paid to the examiners in medicine and in midwifery respectively.

The committee also recommended to the Council the adoption of the following resolution :—

That a committee of seven members of the Council, to be called the "Nomination Committee," be appointed to nominate candidates for the several examinerships of the College, excepting candidates for the Court of Examiners and for the Court of Examiners' section of the Dental Board, subject to such rules and regulations as the Council may hereafter enact.

The committee again reserved to a future report the result of their deliberations with respect to the curricula of professional education of this College as compared with those of other institutions.

THE EXHIBITION OF THE ROYAL ACADEMY OF ARTS.

There is but little to interest us from a medical point of view in the present Exhibition. Amongst the sculpture are busts of the late Drs. Murchison and Leared, the former intended to be placed in St. Thomas's Hospital. There is a fair suggestion of Murchison's massive head, but the likeness, which we suppose is posthumous, is not striking. Mr. Bruce Joy exhibits the statue of Harvey, executed by him for the Harvey Tercentenary Memorial at Folkestone. Amongst the paintings we would especially note Mrs. Butler's (*née* Thompson) "Defence of Rorke's Drift." This is a very powerful work. It contains portraits of Messrs. Chard and Bromhead, and of Surgeon-Major Reynolds, who is conspicuous amongst the defenders. There is some comparatively new work of promise, and we would especially refer to "Peace and War," by John R. Reid; "St. Ann's Almshouses, Antwerp," by W. Logsdail. "A Frightful State of Things," by Gaetano Chievici, full of humour and admirably painted, will, we predict, be one of the most popular pictures in the Exhibition. The feathered inhabitants of a farmyard have penetrated into a cottage where a child has been left alone, and its consternation at the intrusion of the unexpected visitors, all of which are portrayed in a marvellously truthful and humorous way, is exceedingly funny. The Exhibition contains some good examples of Tadema, Leslie, Marks, Prinsep, Stone, Fildes, Hardy, and other favourite painters. A good deal of interest attaches to a portrait of the late Earl of Beaconsfield, by Millais, which is placed on a screen in the large room. It is a striking painting, which represents, we believe, the work of only three sittings. An extraordinary idea of the wide range of subject traversed by this remarkable painter is conveyed by turning from the figure of the lovely young girl in the picture called Cinderella to this portrait. Mr. Propert sends a mezzotint etching, which is an effective rendering, in what is perhaps the form of engraving most nearly allied to colour, of a subject which the artist has already treated with great success in etching, "A Relic of the Past." There are also some clever etchings by Dr. Evershed, whose work is always true and good.

ROYAL COLLEGE OF PHYSICIANS.

A meeting of the Fellows of this College was held on Thursday, the 28th inst., under the presidency of Sir W. Jenner, Bart., K.C.B.

The following gentlemen were admitted to the Membership of the College :—

Bradshaw, James Dixon, M.B. Oxford.
Haynes, Frederick Harry, M.D. London.
McAlister, Donald, M.B. Cambridge.
Meeres, Edward Evan, M.D. London.
Moritz, Siegmund, M.D. Wurzburg.
Nall, Samuel, M.B. Cambridge.
Taylor, Seymour, M.B. Aberdeen.

And the following members nominated by the Council were duly elected to the Fellowship :—

James Lewis Siordet, M.B. London.
John Wale Hicks, M.D. London.
John Baptiste Potter, M.D. Edinburgh.
James Watt Black, M.D. Edinburgh.
Francis de Havilland Hall, M.D. London.
William Ewart, M.B. Cambridge.
David Bridge Lees, M.D. Cambridge.
Francis Charlewood Turner, M.D. Cambridge.
Joseph Ewart, M.D. St. Andrews.

It was decided that the first Bradshaw lecture should be delivered, in accordance with the terms of the bequest, on the 18th of August next, the President being empowered to nominate the lecturer.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons on Monday a petition for alteration of the Lunacy Laws was presented from Limerick. A petition was presented from Lambeth in favour of a motion of which Mr. Reid has given notice for the prevention of vivisection. The general abstract for 1880 of marriages, births, and deaths in Ireland was laid upon the table. Amongst other returns presented were the Charter of the Royal University of Ireland, and a list of the members of the Senate. The Alkali Works Regulation Bill passed through Committee *pro formâ*. Earl Percy gave notice that he would move to refer the Metropolitan Open Spaces Bill to a Select Committee.

On Wednesday, a Bill for better securing the purity of beer was brought in by Colonel Barne, Mr. Storer, and Mr. Hicks, and fixed for second reading on July 20th. Mr. Hopwood gave notice of a question for May 5th, as to the operation of the Contagious Diseases Acts at Dover, and the attempted suicide of a girl named Elizabeth Burley, through fear of the police officer appointed to carry out these Acts.

Non-Vaccination Penalties.

On Thursday, Mr. P. A. Taylor asked the President of the Local Government Board whether it was true that Mr. John Abel, of Farringdon, has been prosecuted thirty-four times for refusing to have his children vaccinated; and whether he proposed to bring in any measure to limit the amount of punishment inflicted for non-compliance with the Vaccination Acts. Mr. Dodson said he believed the statement was correct, but the Local Government Board were not responsible for these repeated prosecutions. They had in more than one circular advised boards of guardians to act with caution and moderation. As to the last part of the question, looking to the scant encouragement which was given last year to his Bill, limiting the number of prosecutions, he was not prepared to bring in another Bill this year.

Small-pox Hospitals.

Mr. Pell asked the President of the Local Government Board whether the Metropolitan Boards of Guardians and Vestries had replied to the letters addressed to them by the Local Government Board on February 23rd, 1881; and if he could inform the House what extent of provision had been or was being made for hospital treatment and isolation of pauper and non-pauper cases of small-pox in the metropolis. Mr. Dodson said all the boards had replied. Fourteen

Boards of Guardians had undertaken to provide some accommodation for cases belonging to the pauper class, and fourteen district boards and vestries had given similar undertakings with regard to cases belonging to the non-pauper class. He could not say the extent which that accommodation would reach, but looking to the extent of the epidemic he feared it would be inadequate. The beds in the hospitals under the Asylums Board, numbering 968, were at present full.

Colonel Makins gave notice that to-morrow he would ask whether the authorities have cut off and annexed a portion of the public road leading from the Fulham-road to the River Thames, and are erecting upon it a temporary building for the reception of small-pox patients, and whether it is the intention to remove pauper patients to that building within the next twenty-four hours.

Correspondence.

"Audi alteram partem."

THE OLD UNIVERSITIES AND THEIR MEDICAL DEGREES.

To the Editor of THE LANCET.

SIR,—Your leading article of this day on the medical degrees of the old universities and Dr. Morgan's pamphlet respecting them render it desirable that the case of the old universities in relation to their medical degrees should be clearly stated. You rightly say that a doctorate in medicine "ought to mean something more than a common minimum qualification," and that "nobody who has the reputation of the profession at heart wishes to see graduation made too easy." By this you doubtless mean that a higher standard of education, general, scientific, and professional, should be required for a degree than for a minimum qualification, and that if it were not so the degree would be no more worth having, no more an object of ambition, than the minimum qualification. In short, it will be admitted, I suppose, that medical degrees, like most other things, bear a value somewhat proportionate to the difficulty of obtaining them; and there is little doubt that the difficulty of obtaining the degrees at the old universities, in time past, gave a prestige to medical degrees generally, and so enhanced the value of the degrees which were obtained on easier terms in other places. To maintain the character and high estimation of their degrees is therefore a duty which the old universities owe to the profession, to their graduates, and to themselves. They have done it hitherto, they do it now; and you and others will desire that they should continue to do it by the education required, as well as by the social benefits resulting from a residence in them, and from the free intermingling in them of students preparing for the various higher walks of professional, political, and other life.

Now, bearing in mind the fact that higher education necessitates longer time, and therefore proportionately more expense, and that every father who wishes to give his son the advantage of a university education and a university degree must be prepared to incur somewhat greater expense than if he were content with a minimum qualification, the questions we have to answer are these. Do the old universities offer reasonable facilities for obtaining their degrees by intelligent and industrious men—the men, that is, who ought to have them? Do they in any way discourage such men who seek the medical degrees? or do they hold out a welcoming and assisting hand to them?

At Cambridge, and I speak of this university only, the case is as follows: The student must undergo a test of his general education, which he may do at the "Previous Examination" in his first term of residence, or, which is better, before he comes into residence through the "Local Examinations." The "Higher Local Examinations," or the "Oxford and Cambridge Schools Board Examinations." The real difficulty lies in this matter of general education; and considerable experience, as teacher, examiner, and member of the Medical Council, convinces me that not very much progress will be made in improving medical education till an improvement in the early school teaching of our boys has been effected. To make them more apt and intelligent as medical students they must have better mental training in their school work. The Cambridge student must reside three years in the university; but, if he has had sufficiently good school training to enable him to satisfy the requirements at one of the examinations above-mentioned, he may devote his whole time in the university to the scientific and practical study of medicine, may obtain the B.A. degree through the Natural Sciences Tripos, and have completed his botanical, physical, chemical, anatomical, and physiological studies, as well as have made some progress in clinical study at the hospital, before the expiration of these three years. That is to say, he will have advanced himself in his medical course during the three years at Cambridge as much as he would have done during the same period at any other place, or nearly so. I say or nearly so because the examinations in these subjects here are somewhat more difficult and take a somewhat wider range, and therefore need somewhat longer time for preparation, than do the corresponding examinations for the ordinary qualification. The standard of the examinations ought not to be lower than it is, and the time spent in preparation for them ought not to be less. But the facilities for the study of these subjects are as great and as good in Cambridge as they are elsewhere; and a youth who is ready to come to Cambridge, as evinced by the fact that his general education will meet the requirements I have mentioned, will find that three well spent years in Cambridge will carry him to the point in his professional course which I have denoted. Naturally, if he has not been able to give the required proofs of general education before he comes, or in his first term, his university period will be partly occupied in work which ought to have been done at school, and a longer time will be required before he can pass the medical examinations. The proper proceeding, which I hope ere long will be the general proceeding, is to satisfy the requirements in school education through the "local" or "higher local" or the "Oxford and Cambridge Schools Board" Examinations *before* coming to Cambridge, so as to be able at once, on coming here, to commence medical study and continue it steadily through the whole period of residence.

With regard to expense, £150 a year is a fair average estimate for those who belong to a college, and who have the advantages, supposed or real, of college life, superintendence, and associations. Some spend more, and some, not a few, spend less. The non-collegiate students, who can regulate their mode of life as they please, spend, in many instances, not more, in some less, than £80 or £90 a year. At Cavendish College, which has been instituted for the purpose of enabling students to come to the university at an earlier age than they could otherwise do, and at less cost, which is under excellent management, and which already contains several medical students, the entire sum, including university, lecture, and other fees, is £80 a year. Selwyn College is growing up for a similar purpose, and, by a simple mode of living, expects to limit the whole charge for tuition, room rent, board, and attendance, to about £80 per annum.

I do not take into account the great number of scholarships, exhibitions, and prizes which are scattered among those whose school education is somewhat above the average, and which fail to produce the effect they long ere this ought to have had upon school teaching. These are open to men who intend to pursue medical study as well as to others, and a good many are given for natural science, but I am never anxious to hold them out as a bait, and I never particularly desire to divert them, to any great extent, into being rewards for medical study. The purer and less money-seeking we can keep that study the better, relying upon the genuine interest of the work, and the stimulus afforded by the hope of future success in the profession.

The University looks with no unfriendly eye upon the natural science and medical students, supplies the means of teaching them with liberality, and regards its growing medical school with interest and satisfaction. There are good laboratories, museums, dissecting-rooms, lecture-rooms, &c., a good hospital, and a staff of able earnest teachers. The fees required of the students are small in consequence of the stipends of the teachers being paid, in part, out of the university chest; and the teaching and work are not, as in former times, restricted to the terms, but are continued in the vacations.

It is not to be expected that the medical and surgical degrees, with qualification to practise, can be obtained in less than five years of medical study. Of these, as I have said, the first three may be spent in Cambridge. Some students remain longer; but I think it will be generally agreed that in the case of this and other non-metropolitan schools it is advisable that the latter part of the period should be spent in the wider field of observation which a metropolis affords.

I think I have shown that the university is not unmindful of the wants of the profession and of medical students, and that its medical degrees are obtainable as easily, with as little expense and in as short a period of time, as ought to be the case with the medical degrees of a university, certainly of a university which holds the high rank of one of the old universities of England. I may add that the profession shows its consciousness of this by the annually increasing number of those who come into residence with the view of pursuing their medical studies, and obtaining the medical degrees. I am, Sir, yours, &c.,

Cambridge, April 9th, 1881. G. M. HUMPHRY.

To the Editor of THE LANCET.

SIR,—In order to remove any misconception of the position of the Durham University in regard to medical graduation may I be permitted to direct your attention to the steps lately taken by the Senate to remove the restrictions by which candidates for its medical degrees have until recently been hampered.

Firstly, as regards preliminary education. Instead of graduating in arts, or passing an arts examination equivalent to that for graduation, candidates are now required to pass in four arts subjects only in addition to the ordinary registration examination. Of these subjects two are compulsory — viz., Greek (Xenophon, Book ii.) and Euclid, Books iii. and iv.; the other two being selected at the option of the candidate from the following list — viz., Latin (Cicero, "De Amicitiâ"); French (Sainte Beuve's "M. Daru"); German (Freytag's "Der Staat Friedrich's der Grossen"); mechanics, with hydrostatics and pneumatics; and English History before the Norman Conquest. From this examination candidates are excepted who have graduated at, or passed the extra-professional examination of, a recognised university, or have passed the preliminary examination qualifying for the Membership of the College of Physicians of London.

Secondly, as regards professional education. Candidates must fulfil a curriculum very similar to that required by the College of Physicians of London; but of the time spent in study one winter and one summer session must be passed at the University College of Medicine, Newcastle-upon-Tyne. Two professional examinations must also be passed—one the First M.B., including anatomy, physiology, chemistry, and botany; the other the Second M.B., including medicine, surgery, midwifery, and allied subjects. Candidates may pass the First M.B. examination before they commence their attendance at Newcastle, and before they pass the extra arts examination. As the regulations stand at present, therefore, there is nothing to debar any student from graduating at Durham, even should he not determine so to do, until late in his course of study. As a matter of fact, the reforms indicated were introduced three or four years ago; the numbers of those graduating have doubled year by year. During the present session there will have been between fifty and sixty candidates, many of them already qualified as practitioners, examined at the First M.B. examination. It is probable, then, that the great field for practice here alluded to in your article of April 9th will soon be fully utilised, and that it will no longer be thought that Durham has failed in its duty to the profession.

I trust you will be able to find room for this explanation, though somewhat lengthy, since, I fear, some misconception might arise as to the present position of the University from a perusal of the article in question.

I am, Sir, yours faithfully,
LUKE ARMSTRONG, M.D.,
Registrar of the University of Durham
April 12th, 1881. College of Medicine.

IRELAND.

(*From our own Correspondent.*)

A GRAND fancy dress ball was held in Cork last week in aid of the funds of the North and South Charitable Infirmaries, and proved a brilliant success. Nearly 400 attended, and great credit must be given to the Ball Committee, whose arrangements were carried out in a most satisfactory manner.

The usual annual election of examiners for the Royal College of Surgeons in Ireland will take place on Tuesday next, May 3rd, when the Council will proceed, according to the provisions of the Supplemental Charter, to elect from among the Fellows eight examiners to examine candidates for fellowship and letters testimonial; three examiners for the diploma in midwifery, and a similar number to examine students as to their proficiency in general education.

The President of the Royal College of Surgeons in Ireland, in recently conferring the Honorary Fellowship of the College on Professor Helmholtz of Berlin, stated that the distinction had been accorded to foreigners on five occasions only, and that the only ground upon which it was conferred was eminent service in the science of surgery, or in any of the branches of knowledge auxiliary thereto. Professor Helmholtz, the President added, had, by his invention of the ophthalmoscope, wonderfully increased the knowledge not alone of diseases peculiar to the eye, though there its utility was most marked, but in the recognition and differential diagnosis of many other diseases, especially those implicating the nervous system. The College most cordially and respectfully tendered to him this tribute of their admiration, and begged his acceptance of the honour he so well deserved, the only regret being that it was not more proportionate to the magnitude of his services to science, and his life-long devotion to its successful cultivation.

At a special meeting of the Guardians of Newry Union, held last Saturday, the salary of Dr. Mills, Medical Officer of Donaghmore Dispensary District, was, at the recommendation of the Dispensary Committee, increased to £120 per annum, the same amount as the other medical officers of the union receive.

At Rathmines, near Dublin, a gentleman named O'Hare died recently at the alleged age of 103 years and three months.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 21st inst.:—

Bontein, Courthope Sims, Victoria-park.
Burroughs, Leopold, Lee, Kent.
Collings, Charles d'Auvergne, Guernsey.
Copner, Arthur Lewis, Bedford.
King, Ernest Edward, L.S.A., Saffron Walden.
Kinneir, F. W. Edward, L.S.A., Sherborne, Dorset.
Knaggs, Henry Valentine, L.S.A., Camden-road.
M'Lennan, Warwick Guy, Devonport.
Morgan, William Pierce, L.S.A., Dowlais.
Pedley, Frederick Newland, Camden-road.
Robinson, Wilford Vidal, Sydney-place, S.W.
Rooke, Charles, Melbourne, Australia.
Sellers, W. H. Irvin, M.B. Edin., Preston.
Trevor, Henry Octavius, L.S.A., Nether Stowey.
Van Buren, E. C. Haward, Leavesden, Herts.
Warner, Percy, Fareham, Hants.
White, Edwin Francis, L.S.A., Putney.
Yeatman, John Walter, Kilburn.

Of the 77 candidates examined on the 19th, 20th, and 21st inst., 51 passed to the satisfaction of the Court and obtained their diplomas; 5 passed in Surgery, and when qualified in Medicine will be admitted Members; the remaining 21, having failed to reach the required standard, were referred for six months' further professional study. Seven candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical qualification recognised by the College, were also admitted Members.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on Monday, Tuesday, and Wednesday last:—

Ernest F. Neve, F. Ashwell, Francis W. C. Haultain, J. W. Whyte, William A. Giles, Alfred J. Neale, Herbert Fitton, Charles H. Bourne, William C. Woods, Herbert J. Gilbert, Harold F. Watkins, John B. Nash, Alfred P. Hillier, Arthur C. Keep, Thomas A. Fraser, William Hunter, Rivis Mead, Alexander Stables, A. S. Bowman, and Thomas R. Bailey, Edinburgh; Elliott W. Welchman, Edward D. Vinrace, Charles Arblaster, and Arthur W. Scott, Birmingham; Alfred B. Taplin, Alfred B. Bake, Bernard Blower, Joseph Walker, Frederick C. Larkin, and Thomas D. C. Barry, Liverpool; Thomas J. Walker, William E. Bennett, George T. Woods, and Edward J. Byrd, Leeds; Louis Verrey, Leipzig; Walter F. Chappell, Toronto; Oliver Sunderland, Albert E. Tunstall, and John W. White, Glasgow; Frederick Maude, Aberdeen; William A. Jones, William J. T. Barker, and Harding H. Tomkins, Bristol; Alfred W. Hunton, Owens College, Manchester; George F. Gutheridge, St. Mary's Hospital and Edinburgh; Thomas P. Beddoes, Cambridge; Harold G. Hathaway, St. Bartholomew's Hospital; Arthur H. W. Clemow, Liverpool and Edinburgh; Vernon J. Greenhough, Cambridge and Edinburgh; Ernest C. Arnold and Maurice J. Doidge, Cambridge and St. Mary's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 21st:—

Griffiths, Ernest Edward, Heber Villa, Kingston-hill.
Heron, Alexander Woodburn, Lorne House, Westcroft-road, N.W.
Robinson, Alfred, West Cross, Swansea.
Roe, Robert Bradley, Melbury Osmond, Dorset.
Thomas, George Trevor Harley, Gloucester-street, Warwick-square.
Williams, John Frederick, Cosham, Hants.

The following gentleman also on the same day passed the Primary Professional Examination:—

Teevan, Henry, Middlesex Hospital.

At the Preliminary Examination in Arts held at the Hall on April 22nd and 23rd, 149 candidates presented themselves, of whom 97 were rejected, and the following 52 passed and received certificates of proficiency in General Education:—

George F. Aldous, George R. Anderson, Frederic Barker, Mark A. Barr, Edwin A. Barton, William H. Booth, W. H. C. Candler, H. H. Corbett, A. T. Croucher, Albert W. Daggs, P. J. Denysson, G. F. W. Ewens, C. E. S. Fleming, William Hall, C. R. Harper, Edward J. Hawkes, A. W. Hayles, Edward Howard, D. L. Hubbard, James A. Hutton, L. P. Jackson, Alfred F. J. W. Jones, James Jones, Lión V. O. de Lassasic, K. W. J. Mackenzie, James F. Magill, S. Mellor, Colin D. Morris, Theodore Murphy, William Murphy, C. E. Oldacres, W. J. Olivey, Arthur J. Owen, N. A. Partridge, H. H. St. J. Pickstock, J. B. B. Protheroe, S. W. Read, Joseph A. Rogers, W. R. Scoging, Edmund Symons Smith, Henry Sandford Smith, H. A. Spencer, P. C. H. Strickland, Horace L. Swete, C. Terry, Lucy Alice Vick, L. Whitehead, Alexander Whyte, Lionel H. Williams, T. Gill Williams, Arthur E. Wilson, Richard Trood.

UNIVERSITY OF ST. ANDREWS. — The following gentlemen, having passed the required examinations, had the degree of Doctor of Medicine conferred upon them on the 21st inst.:—

Call, Thomas James, M.R.C.P. Edin., L.F.P.S. Glasg., L.S.A. Lond., Ilkley, Yorks.
Chaple, Charles, L.S.A. Lond., London.
Finucane, Thomas Dawson, L.F.P.S. Glasg., L.A.H. Dub., L.M., Black Rock, Dublin.
Lycett, John Allan, M.R.C.S. Eng., L.S.A. Lond., L.R.C.P. Lond., L.M., Wolverhampton.
Mackay, John Sutherland, M.A. Edin., M.B. & C.M. St. And., Huelva, Spain. (In absentiâ.)
Murray, William Fettes, F. & L.R.C.S. Edin., Forfar.
Oxley, Martin Gay Black, M.R.C.S. Eng., L. & M.K.Q.C.P. Irel., Liverpool.
Spooner, Edward Monro, M.R.C.S. Eng., L.S.A. Lond., Blandford.
Tibbits, Herbert, M. & F.R.C.P. Edin., L.R.C.P. Lond., M.R.C.S. Eng., London.
Tily, James, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond., L.M., Richmond.
Trend, Theophilus W., M.R.C.P. Edin., M.R.C.S. Eng., L.K.Q.C.P.I., Southampton.

At the same time the following gentlemen had the degree of Bachelor of Medicine and Master in Surgery conferred upon them after examination:—

Hanson, John Edward, L.R.C.S. Edin., London.
Lowe, George, L.R.C.P. Edin., Darlington.
M'Munn, John Alexander, L.R.C.S. Edin., Belfast.

The following passed the 1st M.B. Examination:—

Bowie, Alexander, Edinburgh.
Redpath, Robert Knox Wighton, Edinburgh.

UNIVERSITY OF EDINBURGH. — The following degrees have been recently conferred:—

M.B. & M.C.—Robert Scott Skirving, Scotland.
M.B.—Robert Wilkie Smith, Scotland.
B.S. IN PUBLIC HEALTH.—Robert C. Smith, M.D., Ardwick; James Anderson, M.B., Ulverston.

The following candidates have passed the Second Professional examination for Medical Degrees:—

F. Ashwell, T. R. Bailey, G. J. H. Bell, J. S. Bolton, J. R. H. Bond, C. H. Bourne, John Bowie, A. S. Bowman, William Brydon, W. A. Buchan, George Burn Murdoch, P. B. Bury, W. H. Calvert, S. G. Campbell (with distinction), A. K. Christie (with distinction), Philip Cockburn, P. B. Cousland, John Craig, William Davidson, D. R. Davies, A. S. Delépine (with distinction), C. V. Delépine (with distinction), R. G. Dempster, William Dutton, A. B. Dymock, H. J. Fletcher, J. M. Ferguson, B. E. Fordyce, T. A. Fraser (with distinction), G. W. Galletly, Lawson Gifford, F. W. Grierson, C. B. Gunn, G. F. Gutheridge, M. W. Gutteridge, W. W. Hall, H. C. Hallows, F. H. Hawkins, T. K. Hill, A. P. Hillier, Richard Humphreys, William Hunter (with distinction), Granville Jameson, A. C. Keep, Arthur King, P. B. Le Franc, R. T. Lorraine, W. B. M'Donald (with distinction), A. F. Mackenzie, W. G. Macpherson, Robert Mackinlay (with distinction), E. O. Macniven, F. P. Marais, Rivis Mead, A. J. K. M. Mill, J. B. Nash, A. M. Neethling, G. R. Nelson, E. F. Neve, Diarmid Noel-Paton (with distinction), E. S. Palmer, R. W. Philip, G. C. Purvis (with distinction), Herbt. Rendall, G. J. Renwick, R. H. Rozenzweig, T. L. Shearer, G. F. Shiels, David Smart (with distinction), G. A. van Someren, A. E. C. Spence, William Spence, Alexander Stables, Joseph Stapleton, J. N. Stark, Charles Stein, R. T. Sutherland, J. R. Suzor, William Taylor, A. H. Thomas, W. F. Thompson, P. E. Todd, David Treharne, J. A. Turner, W. O. Walker, H. F. Watkins (with distinction), John Whitaker, J. M. Whyte, Ernest Wilcox, H. M. Wilson, Thomas Wood, William Younan.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

CLARK, H. E., L.R.C.S.Ed., L.F.P.S.G., M.R.C.S.E., has been appointed Surgeon to the Glasgow Royal Infirmary, vice Dr. H. C. Cameron, resigned.

DANIELL, R. T., M.B., F.R.C.S.I., has been appointed Surgeon to the T Division of Police, vice A. Godrich, resigned.

EVANS, E., M.B., C.M., has been appointed Public Analyst for the County of Anglesey, vice Owen, resigned.

EWBANK, H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Senior House-Surgeon to the General Hospital, Cheltenham, vice Carden, resigned.

GROGONO, W. A., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Divisional Surgeon to the West Ham Subdivision of K Division of the Metropolitan Police, vice Levick, deceased.

HILL, W., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Obstetric Surgeon to the St. John's House Maternity Home, Chelsea.

HODSDON, J. W. B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Physician in the Royal Infirmary for Sick Children, Edinburgh, vice Fligg, resigned.

HORSFALL, J. S., L.K.Q.C.P.I., M.R.C.S.E., has been reappointed Medical Officer and Public Vaccinator for the Sowerby Bridge District of the Halifax Union.

JACOB, E. H., M.A., M.D., has been appointed Demonstrator of Physiology to the Leeds School of Medicine.

LLOYD, J. J., L.R.C.P., L.M., L.S.A.L., has been appointed House-Surgeon to the Denbighshire General Infirmary, vice W. F. Jones, M.R.C.S., L.R.C.P., L.M., L.A.H., resigned.

MAHOMED, G., M.R.C.S.E., L.S.A.L., has been appointed Resident Medical Officer to the Bournemouth Dispensary.

MILLER, H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Witham District of the Braintree Union.

RYGATE, B. R., M.B., M.R.C.S.E., L.S.A.L., has been appointed District (St. George's-in-the-East) Surgeon to the Royal Maternity Charity.

SHERWOOD, A. P., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Eastbourne and Seaside District of the Eastbourne Union.

SUTTON, Mr. F., has been reappointed Public Analyst for the Borough of Thetford.

WHIPP, R., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Burton District of the Kendal Union.

YOUNG, W. MUSSEN, M.D., has been appointed Assistant Medical Officer to the Suffolk County Asylum, vice Davie Harris, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BAINES.—On the 19th inst., at Birkdale, Southport, Lancashire, the wife of A. H. Baines, L.R.C.P.L., M.R.C.S.E., of a daughter.

BROOKES.—On the 11th inst., at Kennington-road, the wife of Frederick William Brookes, M.R.C.S.E., of a daughter.

BURNEY.—On the 21st inst., at Greenwich Infirmary, the wife of Walter Charles Skardon Burney, M.D., of a son.

MARRIAGES.

ADDY—KNOWLES.—On the 23rd inst., at St. Augustine's, Pendlebury, by the Rev. Dr. Dewes, assisted by the Rev. Dr. Browne, Boughton Addy, M.D. Lond., M.R.C.S.E., of Eccles Old Road, Pendleton, to Jane Agnes, eldest daughter of Andrew Knowles, of High Bank, Pendlebury, Manchester.

HOWSE—MARSHALL.—On the 27th inst., at Effra-road Chapel, Brixton, by the Rev. E. S. Howse, B.A., of Altrincham, Henry Greenway Howse, M.S., of 10, St. Thomas's-street, S.E., to Alice Elinor, youngest daughter of the Rev. T. S. Marshall, of 6, Church-road, Brixton-rise, S.W.

PEARCE—GOOLD.—On the 20th inst., at the Convent Church, Upper Norwood, Henry Pearce, of Hurstpierpoint, to Margaret Matilda (Queenie), daughter of the late Frances Goold, Surgeon in H.M. Bombay Army, and stepdaughter of the late J. R. Roe, M.D., of Bridgenorth. No cards.

ROBINSON — FAWCETT.—On the 21st inst., at St. Nicholas Church, Newcastle-on-Tyne, by the Rev. Canon Martin, M.A., assisted by the Rev. J. A. Sharrock, M.A., Arthur H. Robinson, M.D., of Hull, to Isabel Kate, eldest daughter of J. Fawcett, Esq., of Newcastle.

WALSH—CARTER.—On the 26th inst., at the Roman Catholic Church, Blackley, near Manchester, J. G. Walsh, M.D., of Ormskirk, to Annie, eldest daughter of the late William Carter, Esq., of Crumpsall, Manchester.

WANOSTROCHT—BROWN.—On the 26th inst., at 19, Lutton-place, Edinburgh, by the Rev. J. McLaren (uncle of the bride), Vincent Wanostrocht, M.B., of Escrick, York, to Margaret Lawrie, eldest daughter of Alexander Brown, Esq.

DEATHS.

LYSTER. — On the 20th inst., at his residence, 72, Devonshire-road, Prince's-park, Liverpool, C. E. Lyster, M.D., F.R.C.S.I., aged 46.

STOKES. — On the 15th inst., at Mullingar, Gabriel Stokes, M.D., aged 74.

WILLIS. — On the 17th inst., at Waverley-terrace, Bray, Thomas Willis, sen., L.A.H.D., aged 91.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, May 2.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL INSTITUTION.—2 P.M. Annual Meeting.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Conversazione and Annual Oration, by Arthur E. Durham.

Tuesday, May 3.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar, "On Non-Metallic Elements."

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following specimens will be shown:—Specimen illustrating Molluscum Contagiosum; Two Cases of Liver-abscess following Dysentery; Dysentery with Abscess of Liver; External Hydrocephalus; Specimens of Calculi, &c.; Fractured Cervical Spine; Probable Fracture of Spine; Extra-renal Sarcomatous Growth; Two Cases of Intestinal Obstruction; Sarcoma of Kidney; Heart with Calcareous Plates; Heart with Stenosis of Tricuspid Valve; Atresia of Aortic Aperture in an Infant (card); and other Card Specimens.

Wednesday, May 4.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be exhibited. The President, "On a Case of Phlegmasia Dolens with Lymphatic Varix."—Dr. Galabin, "On a Case of Extra-uterine associated with Intra-uterine Fœtation, in which Abdominal Section was performed."—Mr. George Rigden, "On Statistics of Midwifery in Private Practice."

EPIDEMIOLOGICAL SOCIETY.—8 P.M. Mr. John Spear, "On the Woolsorters' Disease, or Anthrax Fever."

Thursday, May 5.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Magnetism."

HARVEIAN SOCIETY.—8½ P.M. Dr. John Williams, "On a Case of Ovariotomy during Labour."—Mr. James R. Lane, "On Experiences of Antiseptic Surgery."

Friday, May 6.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M

ROYAL INSTITUTION.—8 P.M. Hon. Geo. Brodrick, "On the Land Systems of England and of Ireland."

Saturday, May 7.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor H. Morley, "On Scotland's Part in English Literature."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

AT the primary examination in Anatomy and Physiology, on the 22nd instant, there were 185 candidates, to whom the following questions were submitted:—Anatomy, from 1 to 3 o'clock, when they were required to answer four and not more out of the six questions on both subjects.

1. Describe the upper third of the femur.
2. Describe the tempore-maxillary articulation, and the movements of which the lower jaw is capable. Mention the muscles by which these movements are respectively effected.
3. Give the dissection necessary to expose fully the adductor pollicis in the palm of the hand.
4. What structures are in relation with the several portions of the duodenum?
5. Describe the course and relations of each phrenic nerve.
6. Describe the azygos veins. Give the course, relations, and tributaries of each.

The following were the questions on Physiology, from 4 to 6 o'clock:—

1. State the changes which take place in the various food-stuffs while in the mouth and stomach.
2. Describe the minute structure of the iris. What are its functions? Describe its innervation, and give the central connexions of the nerves supplying it.
3. Describe the structure of the smallest arteries and the capillaries, and the movement of the blood through them.
4. How is the act of vomiting accomplished? By what nerve-mechanisms is it regulated?
5. State and explain the phenomena observed after unilateral section of the spinal cord—e.g., in the dorsal region.
6. What are the changes which take place in the blood while passing through the capillaries of the lungs and those of muscle?

J. B.—We think the physician was in fault in expressing an opinion he knew to be contrary to that of the ordinary adviser without first seeking a consultation.

Mr. J. Poole.—We cannot recommend any work. In any case a medical practitioner should be consulted.

CASE OF SPINA BIFIDA.

To the Editor of THE LANCET.

SIR,—On the 17th December, 1880, I delivered Mrs. Y—— with Barnes's long forceps of a female child. The infant has a spina bifida of the lower dorsal and lumbar vertebræ. The tumour measures four inches by three, and is as large as a moderate-sized orange, and covered with skin partly and thin transparent membrane. The child is also afflicted with hydrocephalus and talipes varus of the right foot, and talipes valgus of the left foot. A shield of gutta-percha has been fitted to the spina bifida to prevent injury.

I am, Sir, yours faithfully,

Braintree, Essex, April 12th, 1881. C. E. ABBOTT, M.R.C.S.

"TALIPES AFTER ACUTE RHEUMATISM.—WHAT TO DO?"

To the Editor of THE LANCET.

SIR,—In reply to "E. G. W.," I would advise that tenotomy be performed, and the limb afterwards put into a proper apparatus. It might be necessary to have recourse again to division of the tendo Achillis. Operation is justifiable, as likely to improve the limb.

I am, Sir, yours, &c.,

SPENCER T. SMYTH, M.D., &c.,
Consulting Surgeon to the Infirmary for Sick Children,
April 25th, 1881. Sydenham-park, S.E.

DEATH FROM CARBOLIC ACID POISONING AFTER INJECTION OF SOLUTION INTO ABSCESS.

DR. E. H. BRADFORD relates, in the *Boston Medical and Surgical Journal*, a case in which death followed the hyperdistension of an abscess with a solution of carbolic acid (1 to 40). The patient was a boy aged five years afflicted with hip disease. A cold abscess had formed on the thigh, pointing on the outer side, which was incised under anæsthesia, and injected with the solution, which was allowed, and by squeezing assisted, to flow out. A drainage-tube was inserted and layers of antiseptic gauze were applied. The next night the patient was seized with vomiting, which persisted. A fresh gauze dressing was employed, but the abscess was not syringed out. Death took place two days later, with symptoms of collapse. At the autopsy diffused hæmorrhage was found in the left lung. The heart contained dark clotted blood. The myocardium was paler than normal, its muscular fibres finely granular. The kidneys were enlarged, firm, and pale; on section the cortex was found increased in volume and of a yellowish-grey colour. The microscope showed general fatty degeneration of the convoluted and straight tubes. The liver was enlarged, firm, and anæmic.

A FRESH START.

MR. COMMISSIONER KERR last week, on taking the chair to which he had been elected by the new Board of Guardians of St. Pancras, gave expression to his views on some important points in parochial administration. The learned gentleman urged an improved system of out-door relief, and offered a suggestion which, in the interests of the class on the borderland of pauperism, we should be glad to see carried out generally by guardians of the poor—namely, that in suitable cases loans might be advanced in place of the distribution of doles, which were soon exhausted, leaving the recipients as badly off as before. He was likewise in favour of the boarding-out of pauper children—a plan the benefit of which has been demonstrated beyond all cavil. Finally he spoke of the need of more careful scrutiny into the circumstances of the inmates of the workhouse and their fitness as objects of indoor relief. The doings of the St. Pancras Board in the past have ofttimes been open to criticism; let us hope that under the able leadership of its present chairman its future career may be characterised by fewer mistakes.

Dr. John Cavafy.—The communication has not been received.

CASES OF SUDDEN OBSTRUCTION OF THE ŒSOPHAGUS.

To the Editor of THE LANCET.

SIR,—I find that I omitted to put in the date of my first seeing Mrs. ——, Case 1, in my paper of the 16th inst. It was on February the 28th, 1880, and therefore the piece of meat, which Mr. Butlin suggests might have been the cause of the obstruction, would have blocked up the œsophagus for nearly three weeks, a long time surely for meat or even gristle.—Apologising for my omission, I am, Sir, yours faithfully,

W. PUGIN THORNTON.

Devonshire-street, Portland-place, W.,
April 25th, 1881.

CASE OF OBSTRUCTION IN THE BOWELS.

To the Editor of THE LANCET.

SIR,—I beg to forward particulars of the following case, if you think it of sufficient interest for insertion:—

On Monday evening, the 7th of March, a female child, two years old, was brought to me with the following history. On the Sunday previous she had passed a natural motion in the morning and appeared well till the evening, when she seemed restless and in pain, and was screaming at intervals all the night and the next day. She had been frequently sick and was constantly straining and passing a little blood from the rectum. There was a perceptible tender swelling in the left flank, dull on percussion. I ordered hot opiate applications to the abdomen and small doses of opium and belladonna every hour. The next morning there was no alteration, and in the evening she seemed worse, so I passed my finger into the rectum, which I found much dilated and containing a soft substance, around which I could sweep the finger, and having at the lower end an opening like a small os uteri (evidently an invagination of the lower colon into the rectum). I tried reduction by injecting water, placing the child on its face and raising the nates, but the water was forcibly returned, and on removing the tube a portion of the colon protruded through the anus. I returned this, and with the finger pushed up the colon as high as I could reach (about the upper edge of the iliac bone), but on removing my finger the colon again descended; so, after again pushing it up, I introduced a large gum-elastic catheter, and, guiding it along the finger in the rectum, passed it some inches above into the colon (as much as appeared to be necessary), and was gratified to find that the reduction was accomplished.

The little patient had no more sickness and slept well all night. She continued her medicine at longer intervals until the following Friday morning, when she passed (in her sleep) a large-sized motion, since which time she has gone on comfortably with one or two motions daily, and is playing about as usual.—I am, Sir, yours &c.,

Kingston-on-Thames, March 23rd, 1881. E. M. SHIRTLIFF.

Nitrous Oxide.—Nitrous oxide, prepared by heating ammonium nitrate, must be purified from nitric oxide by passing through sulphate of iron, and from chlorine by passing through potash, before it can be inhaled with safety.

A Physician (Kensington).—We believe satisfactory arrangements for horse-foraging can be made with Messrs. Hall, of Park-lane, W.

FEMALE INEBRIATES.

To the Editor of THE LANCET.

SIR,—No cases are so difficult to deal with as those of married women who are habitual tipplers; homes are made wretched, husbands get neither peace at their meals nor rest in their beds, are unfitted for their daily work, and can find no "modus vivendi" with such partners—no remedy and no escape! These women are sometimes maniacal and dangerous, but lunatic asylums will not receive them; addicted to pilfering and pawning their husbands' property, but not admissible into prisons; on the verge of brain-softening, paralysis, or liver disease, but ineligible for hospitals. There is an indefiniteness about these cases; they are on the borderland, but not within the territory, of the insane, the criminal, and the diseased. Time and the slow but sure operation of natural laws bring them, sooner or later, within it, and then we can deal with them; but it is quite wonderful how long they will go on before some definite form of disease or crime solves the problem, "What is to be done with them?" and they sometimes wear out and destroy the lives of their husbands and those about them before they themselves become inmates of hospitals, prisons, or asylums. And yet I have known many such women who were, otherwise, good and amiable, who only required separation from certain people and surroundings, removal to a distance, proper associates, a salutary environment, and judicious supervision to make them ornaments and comforts in their homes, and blessings, instead of curses, to their husbands. But how is all this to be accomplished? True, there are "homes" for such women, but they are much too expensive for most men, and the wife must consent to go into them, and this consent is not easily obtained. Then, again, a man's duties may fix him in one spot, and he may thus be unable to change his wife's associates and surroundings, and he may be too poor to give her the benefit of travelling, proper attendants, and so forth; so that in a vast proportion of cases he has no remedy for and no escape from a life that is scarcely endurable. He must bear his heavy trial with patience, and wait for those catastrophes which, sooner or later, result from a persistent violation of moral and physiological laws. I have written this letter in the hope that some of your readers may be able to supply valuable hints and suggestions as to the management of a most painful and difficult class of cases.—I am, Sir, yours truly,

DANIEL HOOPER, M.B. & B.A. Lond.

Trinity-square, S.E., April 27th, 1881.

COLOUR-BLINDNESS.

To the Editor of THE LANCET.

SIR,—At the recent meeting of the Ophthalmological Society, Mr. Carter inquired as to the possibility of colour-blindness being overlooked unless the eyes were separately examined. It may be interesting to mention, therefore, that in an article on colour-blindness in Denmark, by Fontenay (published in the current number of Knapp's *Archives of Ophthalmology*), the author states that each eye was tested in 217 cases, and the two were always found alike. On the other hand, a case, coming under my observation at the Sheffield General Infirmary last summer, appears to indicate the importance in faulty colour-perception resulting from head injury, at all events, of testing the two eyes separately. The patient was a young man aged twenty-one, and about twenty months previously had fallen from one of the large Liverpool docks and sustained a series of injuries, consisting of fracture of the frontal bone, of the inferior maxilla, of the right femur, and of the left wrist. He was stated also to have suffered from concussion of the brain, and quite recently had been the subject of "fits." At the time of his coming to me there was a large depression on the left side of the forehead. He complained of his sight having become worse since the accident, but I regret I find no note respecting its exact condition. Ophthalmoscopically there appeared nothing abnormal. He was hypermetropic, and later I find it stated that R.E. + 1·8th = 20·50, and L.E. + 1·8th = 20·70. But the points I wish to refer to especially have regard to his colour defects. When about to test him, he told me he was not so accurate with colours as he used to be before his accident. But he arranged the wools in Holmgren's test correctly, though he was slow in doing so, and hesitated somewhat. On testing each eye separately, however, he behaved differently. With the right eye he picked out the wools, and arranged them as a red blind would do, whilst with the left he placed the wools, though not so distinctly, as a green blind; he thus seemed red blind with the right, and incompletely green blind with the left. Again, placing the wools before him, with both eyes open, he sorted them once more correctly. It would thus appear that while using both eyes the faulty sense in either eye was counterbalanced by that which happened to be good in the other. The repetition of the tests led to similar results.

I may add that Fontenay, in the paper before referred to, mentions that Niemetscheck has reported four congenital monocular cases, but states that he himself regards them as very doubtful.

I am, Sir, yours faithfully,

Sheffield, April 26th, 1881. SIMEON SNELL.

APOMORPHIA.

At a recent meeting of the Boston (U.S.A.) Society for Medical Improvement, Dr. Fifield reported a case in which a man having swallowed a pint and a half of kerosene, one-third of a grain of apomorphia, given as an emetic, afforded complete relief in a very few minutes.

Mr. Thos. Malpass.—We cannot depart from our rule.

T. F. J.—Certainly.

Student, 81.—Huxley's "Vertebrata and Invertebrata," Gegenbaur's "Comparative Anatomy and Zoology," Nicholson's "Zoology."

A. M. K.—The papers are not published.

"CHRYSOPHANIC ACID IN PSORIASIS."

To the Editor of The Lancet.

Sir,—I am gratified by the repeated testimonies in your columns as to the excellent effect of chrysophanic acid in psoriasis. When I first introduced the drug as a remedy for psoriasis, now several years ago, professional opinion was by no means so unanimous in its favour as it has since become.

Dr. Lee's arguments in favour of the "constitutional" action of chrysophanic acid are excellent, but as I think by no means conclusive. That psoriasis will disappear from parts to which there has been no "direct" application of chrysophanic acid is true, provided always that these parts are fairly near to where the acid has been applied. But this results from the friction of the underclothing, which is capable of causing ointment to travel a considerable distance beyond where it has been applied, and partly perhaps from a certain degree of volatility of the acid, although it is not very volatile. Wherever the acid thus travels it will, if present in sufficient force, always produce the characteristic lurid-hued "chrysophanic erythema." Now, wherever this erythema is met with it is an evidence of the direct—that is to say, the local—action of chrysophanic acid on the skin, but certainly not of any constitutional effect. Chrysophanic acid administered internally to healthy persons does not produce an erythema of the skin.

As to the "congestion of the conjunctiva, no matter where the ointment may have been applied," that is certainly not a constitutional effect. It results from the accidental conveyance of a small quantity of the ointment to the patient's eyes by means of his fingers. I have used chrysophanic acid ointment very largely for several years, but ever since I directed my patients to cleanse very carefully their fingers after applying the ointment to their eruption, I have never had a case where the least "congestion of the conjunctiva" has occurred. The patient first wipes his hands with a rag moistened in benzine, which dissolves off not only the lard, but the chrysophanic acid itself, and after that he washes his hands in soap and water. I began to adopt this precaution shortly after I first discovered the effect of chrysophanic acid in psoriasis.

However, would it not be better that those who think that chrysophanic acid administered internally will cure psoriasis should try the experiment and see whether it will turn out as they suppose? Before doing so, however, Dr. Ashburton Thompson's paper, in the *British Medical Journal* of May 19th, 1877, should be consulted. He relates his experience of 319 observations, and finds that a scruple is a moderate dose for an adult, and that the drug acts as an emetic purge.

The question as to whether chrysophanic acid becomes more altered in the intestines than on the skin may probably be answered in the affirmative. In the form of ointment (if the ointment be made according to my original directions) the acid is in a state of solution in fat; but in the intestine, while a certain portion of the dose of acid would undergo solution in the fatty portions of the patient's food, another small portion would become converted into the soluble chrysophanate of soda.

I am, Sir, obediently yours,

London, April 16th, 1881. Balmanno Squire.

Dr. J. C. Reid (Newbiggin-by-Sea).—We are unable to answer the question put to us, and would suggest that our correspondent write to the author of the paper which appeared in The Lancet of the 23rd April or to the health officer for Aberdeen.

Erratum.—In our notice of "Beri-beri" in The Lancet of the 16th inst., the name of the principal civil medical officer of the Straits Settlements was inadvertently spelt Russell instead of *Rowell*.

ABSTRACT OF A

Clinical Lecture

ON THE

TREATMENT OF SOME FORMS OF EPILEPSY.

Delivered at the Hospital for Epilepsy and Paralysis.

BY J. S. RAMSKILL, M.D. LOND.,

SENIOR PHYSICIAN TO THE HOSPITAL, CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

GENTLEMEN,—You will recollect we gave L—— thirteen grains of bromide of potassium with eight and then twelve grains of carbonate of ammonia, besides the zinc pill and the chloral hydrate and camphor inunction. With respect to ammonia, it has long been known that it increased the action of iodide, and I think it does the same for bromide of potassium. It has also the advantage of being an antacid and stimulant. It is of great use in cases where you administer the iodide and bromide together, and, indeed, in every case where there is much depression. Now, as to bromide of potassium. It is a salt of high diffusive power, readily entering and quickly leaving the blood. It should be given freely diluted, otherwise part escapes from the system without getting absorbed. Besides its well-known power of diminishing central irritability, it has a similar effect on mucous membranes, on the motor and sensory nerves, and even on voluntary muscles. Witness the effect of the salt on the fauces and pharynx, on irritable bladder, in which, however, the ammonium is superior to the potassium salt. The same effect is seen in the mucous membrane and muscular coat of the stomach and intestine, as evidenced by the gastric catarrh, anorexia, torpor of intestine, flatulence, &c., and not less indirectly evident in the manner these evils are removed by capsicum and double acids. We would say, then, that the bromides act wherever the blood carries them, sometimes more energetically. Remembering this, I had a tincture of bromide made after the formula for tincture of iodine, and used it for similar indications; but whether the free bromine was too caustic, or whether bromine has any action at all in epilepsy, I can only say the combination fails to act after the manner of the iodide and its tincture. I am still more disappointed with hydrobromic acid. An acid combination of bromide has seemed to me a most desirable one, but the potassic salt is decomposed by even vegetable acids. We do, indeed, meet with formulæ where dilute hydrochloric and other acids are mixed with bromide; the resulting mixture can only be a solution of hydrobromic acid and a potash salt. And solution of hydrobromic acid itself is of little if any use, at any rate in moderate doses, in epilepsy.

Bromide of lithium is supposed by some to be a more powerful salt than potassium; it contains a larger percentage of bromine than either the sodic or potassic salt, and may therefore be given in smaller doses. I do not think it bad practice to give the potassic salt for a period, and, when its action ceases to be protective, to add small doses of the lithium salt. Of the other salts of bromide of magnesium, calcium, starch, they are of no use in epilepsy. You are all aware that in some cases of specific disease large doses of iodide of potassium are curative; also that in some few cases very large doses, having succeeded to a certain point, then suddenly fail. At this juncture more iodide of potassium will not succeed, but the addition of a few drops of tincture makes a combination which acts magically on specific disease. Remembering this, I have used inunction of the bromides, with oleic acid, with fats, and with vaseline, but after many months of steady trial found all useless. Some bromide did find its way into the system, for traces of it could be discovered in the urine, but not on any occasion did I succeed in getting absorbed sufficient to protect the patient from attacks. Of the various salts, potassium, sodium, and ammonium, their therapeutic value in epilepsy may be expressed as three, two, and one respectively. I think it is manifest that the best epileptic remedies act on the fauces and throat; witness the bromides, belladonna, atropine, hyoscyamus, stramonium, and clover hay. Perhaps this observation may some day lead us to discover other aids to our present therapeutics.

Now as to the dose of the potassium salt. For an adult I have commonly found from forty-five to sixty grains a day to be sufficient. That sufficiency is precisely the object to be aimed at, and beyond the quantity necessary not a grain more should be used, and for reasons to be presently mentioned. Voisin says that the reflex condition of the epiglottis gives him the key to the difficulty. He says a therapeutic dose of bromide is not attained until reflex nausea is suppressed on introducing a spoon as far as the epiglottis; it is not till then that the bulb is certainly acted on, and its excitability diminished. This statement is generally, but not always true. I think you may sometimes successfully combat the attacks without suppressing the condition of reflex nausea, and certainly much more frequently you may produce this condition and not in the least degree affect the number or violence of the fits. Still, it is a frequent coincidence. In your treatment begin with a fairly sufficient dose—say, for a child of eight to twelve eight grains, for an adult fifteen grains; and observe both the progress of the attacks and the excito-motory condition of the throat. Recollect, bromide has much less power over the petit than the grand mal. The more frequent and violent the fits, the more marked will be your success. The most difficult kind of case is one in which several minor attacks occur during a month, with an occasional abortive attack in the intervals. Some authorities, believing the efficacy of the remedy depends on its presence in the blood, give the dose indicated three or four times in the twenty-four hours; others, depending more on the vigour of a larger dose, give the whole quantity in one or in two doses during the day; others recommend the commencement of the treatment by a small dose, which every week is to be increased by a few grains. The objection to this method lies in the fact that in a few weeks you may be giving far more bromide than is necessary to act successfully on the bulb, and may produce bromism—a condition in which all specific treatment ceases, and a host of miserable symptoms of your own creation appear usually *pari passu* with a return of the fits. Surely the end of that case is worse than the beginning. I do not say the plan does not sometimes succeed. But it must be stopped or modified on the first appearance of bromism, otherwise the occurrence of this complication is only a matter of time. Sometimes a small dose of bromide given with care acts badly—that is to say, with reference to the stomach disorder, which usually leads off on the road to bromism. As we used to say in the old mercurial days, "the mercury acts badly—it is set astray"; in other words, the condition of the stomach chiefly, but of the whole system really, was such that the mercury acted as a poison. In such a case you must wait, and give general tonics, double acids, and a fair amount of stimulants. These cases only occur in the anæmic and cachectic. They are rare, for epileptics are not often in bad general health. As far, then, as bromide is concerned, you are to solve this problem: to give just as much bromide as may be necessary to keep off the attacks. Meanwhile you are to improve nutrition and restore mental and bodily vigour by all and every means at your disposal. Without an impaired cerebro-spinal centre, irritable and in a sense weak bulb and neighbourhood, I take it the functional disorder called epilepsy could not exist; and what is true of the cerebro-spinal centre is more or less true of the sympathetic and the entire nervous system. The complaint is, in its chronic form at least, a vast neurosis, having one or two foci or centres of intense irritability, and occasional explosive over-action.

The advent of bromide has certainly done infinite mischief to the advance of therapeutics on epilepsy. I fear that the usual *rôle* is just this. To hear the history of the case, to examine with a view to the discovery of a syphilitic origin, or a coarse cerebral lesion, and, failing to find either, the case is treated by bromide, and left to bromide, and to the *vis medicatrix naturæ*. And the *vis medicatrix* succeeds, sometimes, *plus* the bromide, but that is only either in comparatively recent cases, or where there are no secondary eccentric causes set up, to keep the primary mischief in the cerebro-spinal centres alive. I do not see why, if this were not so, the natural history of a recent case of epilepsy should not be towards cure.

Returning to L——, our diagnosis was mainly irritable and explosive action of bulb, exploding in different directions, at different times, eccentric causes keeping up this condition, and coming chiefly *viâ* the splanchnic from the intestines.

We gave bromide to act on the bulb and neighbourhood especially, to the whole system in a less degree, but the intestine seemed to require additional help. There was probably a condition of constriction and dilatation, the result of local or bowel convulsions, which occurred in the earlier fits. In such a condition we can hardly imagine the functions of the abdominal viscera could be carried on without continually teasing and vexing the sympathetic. And of all the regions of the body there is none which reflects so strongly on the brain. Remember the depression which often attends torpid colon, the melancholy attending constipation, and a similar condition of colon we are speaking of, common in the experience of alienists.

What I wish particularly to say, then, is this that, although this condition of intestine is originally produced by centric disorder in most cases, it in turn becomes a fresh source of irritation, and keeps up the centric mischief. Whether this be so or not, the treatment founded on this supposition gives admirable results. The boy takes daily a pill with valerianate of zinc, aloes, and conium, in addition to the bromide. The bromide was tried fairly and diminished the number of attacks, but when the pill was added they disappeared. It seems the valerianate of zinc allayed the frequent spasm of the intestines, and gave tone; the conium assisted it, and the aloes emptied the bowel in a natural and effective way. Aided by the bromide the irritable bowel was calmed and soothed, the weary sympathetic rested, and the perpetually irritated splanchnics carried fewer disordering messages to the brain. We have forgotten the inunction of chloral hydrate and camphor. Read by the light which experience gives in other cases, I say that sometimes it proves of great value; it is an anodyne, and as an outward application is in the first rank. In neuralgia and local rheumatism it has been of great service in my hands. It would be too tedious for you to hear if I recounted all the local applications I have made, and the regions where I have made them, in hundreds of cases of epilepsy, but I can say that I have not met with such help from any other external application as from this. But, like all remedies for epilepsy, it is uncertain. It seems to have most power over the minor attacks. I have a case where the minor attacks all ceased, and for the first time in the history the full fit was developed. In another mixed case of major and minor attacks it has abolished the latter without having had the least effect on the former. In some cases it seems to possess no action whatever; still, I say, it is a valuable help. Whether it acts by continuity of tissue—improbable enough—or by causing some molecular alterations in the periphery of the nerves, and occasioning the same alteration in the nerve-trunks or in their nuclei, or by reflex action alone, I cannot determine. But I think for many years past we have had too much metaphysics in epilepsy; we have forgotten our function as medical men, and the time has come for therapeutics to claim attention. This boy L——, then, we may look upon as in a fair way of cure. I say so because we have had no occasion to increase the dose of bromide or vary its mode of administration. Let me give you another case who, like L——, is in the hospital.

Mabel M——, aged eleven, was admitted into the hospital on Nov. 23rd, 1880. Her father is a painter. There is no history of fits, paralysis, insanity, or phthisis in the family. Patient has had scarlet, but not rheumatic fever. Her present illness began when she was five years old. They were said to be simple fainting fits. She has always a warning of a coming attack. She feels a curious sensation in the epigastrium. It does not fly to the head. She says simply she is going to have a fit and falls down, as seen in the hospital during the fit. She is convulsed on both sides, and it seems to begin bilaterally. Face is not much affected. There is no tongue-biting or micturition. In five minutes after an attack she says she is all right, but sometimes she says she has a headache and feels sleepy. In duration the attacks last only a few seconds. In frequency she has about three in the week, but sometimes as many in a day. There is no cardiac affection; pupils are large, equal, and react normally; there are no ophthalmoscopic morbid appearances. Her memory is very good, and she is sharp and intelligent for her age. She has frontal headache and some giddiness on the days when she has no fit, but she never feels sick. She has been under medical care, and I doubt not taken bromides. She is a fairly well-formed child, has a large head for her size, looks cheerful; none of the aspects of an epileptic, neither is there anything suggestive of hysteria.

On the 24th ten grains of bromide of ammonium were ordered three times daily, a pill of valerianate of zinc, aloes, and conium every night, and the ice bag to be worn to the cervical and upper dorsal vertebræ three hours, night and morning. On the 25th she had five fits of the character described above.

On January 15th the ice bag was omitted; the headache and giddiness had disappeared, and there had been no sign of a fit. She was discharged on Feb. 15th, without having experienced a single attack since the 25th of November. Meanwhile she had gained weight, and looked and felt in perfect health.

This patient's history and kind of attacks, her intellectual freedom, her aspect, form a fair example of a class of cases not at all uncommon, and in my experience they are amenable to simple treatment, and make comparatively quick recoveries. They are cases where a central irritation is kept up by an eccentric cause, and the latter being removed, the cerebral irritation is easily combated by the application of ice to the sympathetic nerve which issues from the last cervical and upper dorsal vertebræ, and by small doses of any of the bromides. Let me add a word on the value of ice. It it effective in proportion to the youth of the patient and to the acuteness of the case. It is rarely beneficial in the chronic epilepsy of adults.

In conclusion, I do not wish to say that all epilepsies have these secondary exciting causes—that, in other words, every case is to be treated by valerianate of zinc, aloes, and conium; any more than any case of petit mal is to be successfully managed by a treatment of which chloral and camphor inunction forms a part. Further, I do not object to the last new theory of epilepsy, nor in my present frame of mind to any theory which can explain most of the facts. I only maintain in these lectures, that what are usually considered effects of epilepsy do in time assume the *rôle* of causes of repeated attacks, and that the treatment altered to meet this contingency is effectual beyond any other treatment adopted to meet the centric mischief alone.

THE DIAGNOSIS AND TREATMENT OF WHOOPING-COUGH.

BY ROBERT LEE, M.A., M.D., F.R.C.P.,
SENIOR ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

(Concluded from p. 694.)

THE fact of all others which has appeared to me most singular, and certainly the most important in diagnosis, is the frequency with which whooping-cough in very young children is mistaken for some other disorder, that this is entirely due to the belief that the symptom of the whoop must be present in order to satisfy the demands of diagnosis. Without the least hesitation, and without the least fear of exaggeration, I venture to express the opinion that infants whoop but rarely. Instead of expecting such a symptom, I am surprised when it occurs in a very young child, and, on reflection, am still more surprised that we should expect it to do so.

Many medical practitioners must have remarked this fact after some experience of family practice, though I could mention instances of personal friends who have been astonished that they had not noticed it till their own children were the subjects of their observation. That it was well known, and carefully noted, years ago is quite evident, since it was stated and taught by Dr. Cullen. "I have had instances," he says, "of a disease which, though evidently arising from the chin-cough contagion, never put on any other form than that of a common catarrh." And, again, "when the disease beginning in the form of a catarrh is attended with fever and difficult breathing, and with little expectoration, it often proves fatal, without taking on the form of the whooping-cough."

Now this is the form which the disease does assume in very young children, and which quite accounts for its being so dangerous in early life. It is not quite correct to say that it begins in the form of a catarrh. The disturbance of the system is more serious, and, if the question is asked of the parent whether the child has been exposed to cold, it is generally answered in the negative. The symptoms are those which more or less characterise the contagious maladies in their early though rather indefinite stage. The most marked certainly are refusal of food, prostration, restlessness, and loss of flesh, with more or less increase of temperature and quickness of respiration. We are inclined at one time to suspect pneumonia or capillary bronchitis, at another that the cause of the symptoms is dentition, or, if they are not severe, that they are due to some error in feeding. Sir Thomas Watson has followed Cullen when he says that "it begins with the symptoms of an ordinary catarrh arising from cold"; and, to show to what extent he considered the cough diagnostic of the malady, he says, "I should be slow to consider any case a genuine case of pertussis unless the characteristic paroxysms of whooping-cough and the stridulous respiration were present."

There is a symptom which is a serious and frequent one in infants, and that is the occurrence of active diarrhœa. It is true that the diarrhœa is often preceded by vomiting, but, as a rule, when the diarrhœa begins the other symptoms abate, and one of two events occurs: either the infant succumbs, in spite of all treatment, or the disease appears to exhaust itself and the symptoms do not return. The active treatment with purgatives, recommended by Sydenham, appears thus to be indicated to some extent by the natural course which the disease takes in such cases.

Sir Henry Holland pointed out the probable relation between whooping-cough and what used to be called infantile remittent fever, and distinctly expressed the opinion that they would be found to depend on the same active cause.

Before passing on to the subject of treatment there are one or two points which are deserving of notice. One, the most important, that in a family of two or three children, when circumstances compel them to be kept in the same room, and the conditions of ventilation are deficient, the duration and severity of the symptoms appear to increase and the nurse or parent is liable to suffer, from which it would seem that the atmosphere of a close apartment may become more or less highly charged or saturated with the fomites of contagion. Another point is the usual increase of fever, difficulty of breathing, and cough during the night, and it is reasonable to inquire whether this may be due to somewhat similar causes to those which mark the stages of an attack of ague or to some difference in the conditions of the nervous system during the usual hours of sleep.

One point seems worthy of mention, and that is the probable explanation of the fact that sometimes all the symptoms of whooping-cough will suddenly subside, and, after an interval of several months, reappear without any very definite reason, such as exposure to a second infection.

The subject of the treatment of this malady appears to me to be pre-eminently deserving of most serious attention. The infant mortality it has lately caused has grown to surprising importance, as the Registrar-General's Returns have made most evident. The remedies which have from time to time been recommended have been so numerous, that it is probable most practitioners would agree with Sydenham that, with some one exception, which in his case was active purging, they "have tried remedies of almost every other kind, and tried them in vain."

Failing any specific remedy we are naturally compelled to treat symptoms, making use of such agents as are generally recognised as proper for the different morbid conditions of the patient. The sensible practitioner would regard any one remedy with considerable doubt, and, while admitting the value of some few in relieving the frequency and violence of the cough, would combine with them either a febrifuge, a purgative, or a tonic, as the state of the case demanded. Thus in the early stages we might prescribe, as is often done, a combination of belladonna, bromide of potassium, and squills or ipecacuanha; later hydrocyanic acid or alum, or external applications, such as camphor, turpentine, or Roche's embrocation; and finally, when the cough seemed to resist all treatment, we should order with confidence a change of air. I recollect, some years ago, one evening a German merchant called upon me to inquire what remedy we used at the Children's Hospital, as some poor neighbours of his had told him of the good effects obtained by themselves and several others from the treatment. I informed him that we had no special remedies; but as he had come from some distance, and seemed much dissappointed, I ventured to inquire what was the nature of the medicine prescribed. He said it was a mixture of cod-liver oil and steel. Now, there is only one mixture of this kind contained in our Pharmacopœia, so I had no difficulty in satisfying his wishes. But it certainly surprised me to hear that this combination, by no means an agreeable one, had obtained a reputation in whooping-cough cases quite unknown to us. Since then I have used it largely, and with as much benefit as some far more esteemed preparations.

There has been for some years a popular notion that a specific remedy does exist, though in a form which is difficult of application. I refer to the influence stated to be exerted by the exhalations from the waste chambers which form part of a gas factory. From abroad we have statements which show that it is usual for children to be taken to these places at convenient times, and that "this is encouraged" by medical advice. I was informed by one of the physicians resident in Amsterdam, that special arrangements were made for children suffering from whooping-cough; and in our own city, at some gasworks in Holloway, for example, on certain days when the waste chambers are cleared, it is usual for many children to attend at the works with apparent benefit. The question which naturally suggests itself is this, What particular product of coal distillation would probably exert an influence on the contagion of whooping-cough? I am not in a position to answer this question at present, nor do I see how to begin such an inquiry without the assistance of a scientific chemist who has made a special study of the subject. This I hope to obtain shortly. Applying, however, the general principles of the antiseptic treatment, and assuming that there are very likely several agents present in the waste products of coal distillation which would be more or less potent in this respect, I have used largely the common one, carbolic acid, combined with turpentine, benzoin, or one of the fragrant oils. This plan of treatment has become very general, and I have heard some go so far as to say that carbolic acid will cure whooping-cough. This statement has come usually from those of limited experience, though sufficiently good results have been obtained to justify us in pursuing the line of reasoning which first suggested a trial of the remedy. Not long since I was assured by a distinguished member of our profession, who suffered severely from whooping-cough, that the only remedy which afforded him relief was carbolic acid inhalation, that the favourite treatment with bromide of potassium and belladonna was tried with the result that for a few hours the cough was relieved after taking the first few doses, but in a short time the effect passed off, and was followed by increased violence of the cough and painful dryness of the throat. In adults the spasmodic cough is the most serious symptom of the disease, but in infants we have to fear the rapid wasting and frequent diarrhœa perhaps more than the cough. So that I am compelled to admit that the use of carbolic acid inhalation must be limited, but within those limits it may be said to have a special effect. I have no doubt that some have tried the administration of the acid internally in diluted solutions, but in my own experience the results have not been such as to warrant any definite opinion. I have also tried sulphur in frequent and small doses, and have had fairly good results. There is no doubt that, as a general rule, the treatment recommended by Sydenham of purging actively is a wise one, for the distress in respiration and cough is certainly diminished when the mucous discharges from the bowels are encouraged. It may also be observed that a spontaneous diarrhœa in whooping-cough is not to be controlled by opiates or astringents.

It appears to me, then, that we have two distinct symptoms to deal with, and that to a certain extent they are under control. With regard to the laryngeal spasm, there is no doubt we can give relief by the inhalation of carbolic acid; with regard to the diarrhœa, I think the best results are obtained, not by attempting to check the discharges by opiates or astringents, but by the administration of quinine and iron in full doses, and by the application of such combinations as Roche's embrocation, a simple compound of the oils of turpentine and amber to the surface of the abdomen. There is no doubt that infants at the breast are in less danger than those brought up by hand.

In conclusion, I would suggest a trial of other volatile agents for the purpose of inhalation, such as turpentine, creasote, oil of amber, benzoin, &c. The common plan of stirring some tar with a hot poker is certainly attended with benefit, and is largely used in my hospital practice. It is only necessary to observe that if we are to expect relief from this kind of treatment, it should be carried out on proper principles. It is of no practical use to order twenty or thirty drops of carbolic acid to be added to a pint of hot water, and the steam to be inhaled, for the quantity of acid which evaporates is only proportionate to the amount of water given off as steam, and under such conditions it is evident the amount would be infinitesimally small.

Savile-row, W.

COMPOUND DISLOCATION OF HIP; RECOVERY WITH USEFUL JOINT.

BY W. F. TAYLOR, M.D., M.R.C.S. ENG.,
HONORARY SURGEON TO THE WARWICK HOSPITAL, QUEENSLAND.

ON Sept. 1st, 1879, I received a telegram to proceed to the town of Allora, fifteen miles from Warwick, Queensland. On my arrival there, I was informed that at about two o'clock in the afternoon a lad, named J. C——, aged seventeen, was engaged sawing down a tree, when it suddenly fell, pinning him to the ground. He succeeded with great difficulty in extricating himself, and was discovered about half an hour afterwards by his brother, who found him suffering great pain, and unable to move his right leg. Assistance having been procured, he was taken to his residence, distant about a mile from the place where the accident occurred. I found him lying on his back, complaining of great pain in the right hip and leg, and on examination discovered a dislocation of the hip into the obturator foramen, with a lacerated wound of the perineum on the right of the urethra, nearly two inches in length. He was placed under chloroform, and his injuries more fully examined. On introducing the finger into the wound in the perineum, the head of the femur could be plainly felt lodged in the obturator foramen; the greater portion of the external surface of the ramus of the pubes, and the ramus of the ischium were denuded of all muscular attachment. The dislocation was reduced with some difficulty, and the leg and pelvis securely fixed to a long, straight splint. Towards morning the bladder was evacuated spontaneously, when the urethra was found to be uninjured.

Sept. 2nd.—Having remained with him all night, I superintended his removal to the Warwick Hospital in the morning, the journey being accomplished principally by rail, without any bad effects. In the evening the temperature had gone up to 100°; pulse 110. He complained of great pain in the hip, which was relieved by the hypodermic injection of morphia and atropia.

3rd.—Passed a good night, slept frequently, and was comparatively free from pain. Ordered an enema and injection into the wound every eight hours of the following:—Salicylic acid, ten grains; biborate of soda, twelve grains; glycerine, one drachm; water to one ounce.

4th.—Suffered a good deal of pain in the forepart of night, which was relieved by hypodermic injections of morphia and atropia. Pulse 112; temperature 101°. Ordered tincture of aconite, which had the effect of temporarily reducing the temperature and slowing the pulse.

The history of the case for the next eight weeks may be summed up as follows:—Severe pain was at times felt in the hip, which was usually at once relieved by the hypodermic injections. Only on one occasion did he complain of pain on pressure in the neighbourhood of the joint. The wound closed gradually, the discharge being at no time fetid; but the temperature was always above the normal, sometimes falling to 99°, and frequently going up to 101°. The aconite was, after a day or two, discontinued, and five-grain doses of the hydrobromate of quinine given every six, and sometimes every four, hours. In order to facilitate the dressing of the wound, &c., a wooden frame, having strong girth-webbing fastened to it, was placed under him on the bed, so that four men could easily raise him as high as was necessary without disturbing the injured limb. About nine weeks after the accident the long splint was removed in consequence of his complaining of pain in the knee, which was somewhat swollen, the hip being free from pain or swelling, and the wound in the perineum nearly healed. The temperature, however, still averaged 99·3°, although the appetite had been good for some weeks, and the bowels had acted regularly. The day following the removal of the splint a good deal of swelling was noticed in the neighbourhood of the hip, with considerable pain on pressure. A large linseed meal poultice was applied, and the following morning, fluctuation being distinctly perceptible, an opening was made under the edge of a piece of lint soaked in linseed oil and carbolic acid (1 to 4), when about ten ounces of fetid pus escaped; there was also an escape of pus through the nearly closed wound in the perineum. A drainage-tube was inserted, and the lotion ordered to be injected through it into the cavity of the abscess every eight hours, the thigh and hip being carefully bandaged with a soft flannel roller. My colleague, Dr. Margetts, saw the case with me the next day, and we were both forced to the conclusion that some bone mischief had been started, the upshot of which could hardly fail to be disastrous. Contrary to all anticipation, however, the discharge gradually ceased, so that in a week after inserting the drainage-tube it was removed and the opening allowed to close. No bad symptom followed; he rapidly gained strength, and in a short time was able to get about on crutches, the hip being kept fixed by a gutta-percha shield. On the 4th of February he left the hospital, with, as I supposed, the joint in a satisfactory way towards anchylosis; this condition being, I had repeatedly told his friends, the most favourable one that could be expected. About eight months after the accident, to my great surprise I met the young fellow in one of the streets riding on horseback, seated in regular bushman style on a large colonial saddle. He told me that he had just ridden from Allora (fifteen miles), and was on his way back; that he could mount and dismount with ease, and suffered no inconvenience from the hip excepting a little occasional stiffness.

Remarks.—This case may be considered interesting—(1) from the nature of the injury, the head of the femur having been no doubt driven from its normal position right through the perineum, and then retracted into the obturator foramen; (2) the persistent increase of temperature up to the time of the abscess being formed, notwithstanding the satisfactory healing of the perineal wound and the absence of any marked tenderness or swelling of the hip; (3) the rapid formation of the abscess, and its speedy cure; and (4) the mobility of the joint being now sufficient to permit riding on horseback without any inconvenience. The results as above described may be principally attributed to the care taken to preserve absolute rest of the injured parts. The maxims relating to the value of *rest* so ably laid down by the late John Hilton, F.R.S., were adhered to as nearly as possible, and in carrying out these maxims, Mr. Saunders, the resident dispenser of the hospital, afforded valuable and unremitting assistance.

Warwick, Queensland.

ON TRICUSPID STENOSIS.

BY BEDFORD FENWICK, M.D.

(Concluded from page 696.)

B. Prognosis.—This, of course, is very grave, and depends much on the extent of the dilatation of the right auricle and the amount of compensatory hypertrophy it has called forth. The average length of life in these cases was about four years from the commencement of serious symptoms. It is interesting to notice that this fact, and those contained in Table III., bear out Dr. Gilbart Smith's suggestion that tricuspid stenosis probably does not by its advent shorten the life of those already afflicted with mitral constriction, but that it may even act beneficially, and, by equalising the pulmonary pressure, materially save the general economy.

C. Treatment.—This, I need scarcely say, consists mainly in maintaining the general health and the cardiac tone at as high a grade as possible. Two very practical points, however, I would venture to insist upon. First, a restriction of liquids in the diet, and this for two reasons especially—not only to keep the quantity of fluid in the circulation, and therefore the vascular tension, and therefore the cardiac stress as low as possible, but because these cases suffer terribly from even a small degree of flatulent distension; and it is just in these very cases that a small quantity of liquid seems—I presume from the chronic state of catarrh of the stomach and intestines consequent on the cardiac obstruction—to rapidly induce this condition. I have found a dilute acid drink containing peppermint and spirits of ether, well iced and sipped occasionally, very useful in relieving the thirst. Second, the abstraction of blood—locally by leeches over the heart or epigastrium if oppression or pain be great; or generally, *from the arm*, if the cyanosis be extreme—gives a relief which is always great, and sometimes seems almost marvellous in its extent. I have italicised "from the arm," because I believe that to open one of the jugulars in venesection, as has been recommended to relieve cyanosis, would in cases of tricuspid stenosis be almost certainly fatal to the patient; for in those cases in which these veins were examined after death they were found to be much dilated, their coats thickened, and their canals patulous; and this condition would certainly facilitate, if it did not ensure, the entrance of air into the heart, if such a vein were opened. Finally, I may add that repeated bleedings to a small extent seem safer, and appear to give more relief both at the time and subsequently than a large depletion at one time.

5. *Size of the tricuspid orifice.*—The next table shows plainly that the length of life seems to increase with the intensity of the tricuspid mischief up to a certain point, but that when the stenosis becomes very extreme, the average length of life, as might be expected, again diminishes, which again proves to a certain extent Dr. Gilbart Smith's practical observation to which I before referred. The table also conclusively proves that when the stenosis is most extreme there is almost invariably an antecedent history of rheumatism.

6. *Size of the mitral orifice.*—In every case the mitral valves were much diseased and the orifice stenosed. Generally the disease was more advanced and the stenosis greater here than in the tricuspid. Table IV. exhibits the facts more plainly than mere words would do, but it is interesting to note that here the intensity of the stenosis does not seem to depend so closely upon rheumatism, as noted in Table III. in the case of the tricuspid.

7. *Concurrent cardiac changes.*—*In no single case is the existence of any congenital defect noted.* In every case but one (No. 8) the right auricle was found dilated, and often to an extreme extent. In 26 cases, or 56·5 per cent., the aortic valves were diseased. In 14 cases, or about 30·5 per cent., the valves were thickened and incompetent, and in the remaining 12, or about 26 per cent., the orifice was stenosed, and often to an extreme degree. All these twelve cases were females. Their facts are clearly shown in Table V. From which it is evident that when aortic stenosis is present in these cases the mitral stenosis is always extreme, and generally very extreme, and that the tricuspid stenosis is always far advanced; but that its constriction is in every case less than that of the mitral, and that these aortic changes are apparently three times more common, and the average age markedly greater in cases without a rheumatic history, than in cases in which that disease has exhibited itself.

TABLE III.

Size of Tricuspid Orifice.	No. of Cases.			Average Ages.		Rheumatism.			No Rheumatism noted.

No rheumatism noted	9	36·3	5	1	3	—	2	3	4

I think we may now, with these facts before us, discuss briefly the validity of the congenital theory. Placing on the one side the immense disproportion between the sexes, and this in favour of women who are less subject than males to congenital cardiac malformation, the good health which most cases retain unimpaired for many years, the advanced ages to which these patients have lived, the well-marked rheumatic history in the usual percentage of cases, the striking symptoms of the disease when it does occur, the extreme degree of the stenosis in so many instances, the invariable concurrent inflammatory changes on the left side of the heart, the complete absence of note of any cardiac defect, which might be of congenital origin, in these cases, and such a clear history of the progress of an inflammatory disease as furnished by the story of the second case recorded in this paper; and placing on the other side the story of Dr. Peacock's congenital case which, suffering and cyanosed, lived for seven months, and was then discovered to possess a tricuspid orifice of twenty-four lines in circumference (absolutely larger, that is, than that found in twenty-eight of these forty-six adults), and a congenital defect (two small holes) in the septum ventriculorum, and the facts that *one* of these forty-six cases was subject to lividity and dyspnœa from an early age, and that three or four more were "delicate" or badly developed—weighing these, I think it will be at once allowed that, in adults at least, the disease does not "date from fœtal life."

I would end this paper by deducing from the facts the following conclusions :

1. That tricuspid stenosis is not so rare as it is generally believed to be.
2. That it attacks women far more frequently than men, in the proportion perhaps of about 8 to 1.
3. That death rarely results from it before twenty or after fifty, and that it most commonly occurs between twenty and thirty, the number of its victims steadily diminishing thereafter with each semi-decade.
4. That in 50 per cent. of the cases there is a well-marked antecedent history of acute or subacute rheumatism.
5. That in every case the mitral orifice is also stenosed, and generally to a greater degree than the tricuspid.
6. That the right auricle is in every case more or less dilated.
7. That in 56·5 per cent. of the cases the aortic valves are also diseased, and that in about 26 per cent. of the cases the orifice is stenosed.
8. That tricuspid stenosis *when found in adults* is due to disease acquired in after-life, and probably never of congenital origin.

TROPICAL RINGWORM OR SKIN FUNGUS.

By JAMES STARTIN, M.B. Cantab., &c.

The tropical ringworm or skin fungus, though rarely seen in England, is by no means an unimportant affection of the skin. It is most common in the tropics, especially amongst the natives of Ceylon, Burmah, West Indian Islands, and the Pacific Islands, but it does not confine itself to these alone, for it is to be found amongst the well-to-do classes, and more commonly amongst men than women. The usual situation is upon the inner surface of the thighs and perineum, the scrotum and buttocks and upon the pubes; it may also be seen about the axillæ and calves of the legs.

Cause and pathology.—It is now an undisputed fact that this troublesome eruption, known hitherto by the name of eczema marginatum, is due to a fungoid parasite, not to any degenerative process of the epidermis alone, as has been described by some authors. Kaposi, Köbner, and others I believe now are acknowledging it to be a parasitic disease. From those parts of the body where the folds of the skin come together, as the buttocks, scrotum and thighs, and the axillæ, the secretions are poured out, and afford a pabulum to the fungus, which is increased by tropical heat and moisture. This irritates and macerates the epidermis. We have then a vesicular, eczematous eruption caused, which is secondary to the primary cause. Living in damp situations or houses, sleeping in damp sheets, are no doubt common causes. Who has not seen mould on a sheet that has been put by in travelling? and in tropical climates this is a very active fungus. The parasite differs from the ordinary British ringworm, inasmuch as its growth is much more luxuriant, and it does not destroy the hairs; nor do I find the parasite in the root-sheath of the hair.

Symptoms.—This disease begins with an intensely irritable spreading eruption, showing vesiculation and erythema at its margin; its course is very slow and its nature very chronic. Like British ringworm, it spreads in circles, only in a much larger area, and chooses the covered parts of the body for its attacks, and those where the perspiration is poured out the most. It is influenced greatly by the tropical heat, in producing fermentation of the secretive processes of the skin in a peripheral direction, which, no doubt, is the pabulum of the fungus germ. The eruption is slightly above the surface of the skin, beginning at first as a small red and irritable circle, about half an inch in diameter, rapidly increasing in size, with small bright scales on its surface; or, if in contact with other skin surfaces, is of a greyish or intensely red appearance, increasing in irritability and vesiculation with the progress of the eruption.

Diagnosis.—This eruption can be at once recognised, by those who have seen examples of it, by its unmistakable appearance, its situation, and its microscopical appearances. It is liable to be mistaken for gyrate psoriasis, eczema, syphiloderma, intertrigo, and pruritus.

Treatment.—Tropical ringworm or skin fungus is a most obstinate eruption to cure. Even if it is relieved in England, as soon as the patient returns to the tropics it is most likely to break out again, unless completely eradicated; at least this is my experience. Oleate of mercury (20 per cent.) is a valuable remedy, or liquor carbonis detergens painted over the affected parts is effectual. Hebra's sulphur and tar application is also good, and Goa powder is much used in India with stated good effects. I use carbolic oil with a few grains of red oxide of mercury with much success.

The following cases, illustrative of the disease, which have come under my notice, are typical examples :—

Case 1.—A gentleman consulted me for an eczematous eruption and ulcer upon his legs, and upon further examining the skin I found a distinct and well-defined marginate eruption on the inner surface of the thighs and perineum, which he told me he had contracted in the West Indies, and which caused him a good deal of irritation, and that he had never been able to get rid of it. On microscopically examining the scraped skin spores and mycelium were found of large size. I prescribed carbolic oil and a preparation of mercury, which effectually removed the eruption.

Case 2.—A man came under my notice at the hospital suffering from a precisely similar eruption on the inner surface of the thigh and buttocks. He had lately come home from Ceylon. I used to this case oleate of mercury (40 per cent.), but had only the opportunity of seeing the case once.

Case 3.—A gentleman consulted me with a similar eruption, which he informed me he had had quite twelve years, round the inner surface of the thighs, scrotum, and spreading upon the nates; it was intensely irritable. Upon microscopic examination it was proved to be parasitic. In this case I used a preparation of iodine liniment, oil of Cade, and hyposulphite of soda with much success whilst he was in England, and I have since heard from him that he was very much better.

These three typical cases, and several others I could have noted, are all interesting on account of the parasitic origin of the affection, and the influence that tropical climates have upon the fungoid parasites of the skin.

Sackville-street.

Bristol Royal Infirmary.—Last week a public meeting, presided over by the Mayor of the town, was held in the Guildhall with the view of raising a fund to clear off the debt of £10,200 now existing on the Royal Infirmary. Resolutions in harmony with the purpose of the meeting were enthusiastically carried, and it is expected that the object which the friends of the institution have so much at heart will be speedily achieved.

COMPLETE APHONIA OF NEARLY FIVE YEARS' STANDING, CURED BY THE REPEATED APPLICATION OF FARADISATION TO THE VOCAL CORDS.

BY ROBERT TORRANCE, L.R.C.P. EDIN.,
SURGEON TO THE NEWCASTLE-ON-TYNE THROAT AND EAR INFIRMARY.

MISS A. P——, aged twenty-four, consulted me in October, 1880, for loss of voice of nearly five years' standing. She looked delicate, but did not complain of weakness, and informed me that she had had an ulcerated sore-throat, and lost her voice on leaving a heated room in November, 1875. On recovering from the sore-throat, her voice did not return, when the regular medical attendant applied caustic two or three times, but without any beneficial effect. She then consulted several eminent practitioners, and amongst them a leading physician in Dublin, who recommended galvanism to be applied by means of a battery, but the result was the same as before. Preparatory to my making a laryngoscopic examination, it may be stated that the fact was proved that the loss of function was not due to hysteria, as she was placed completely under the influence of chloroform, when she did not speak, but continued to whisper. The instrument then showed that the vocal cords were in a very relaxed state, and crumpled up as it were near their middle, but otherwise apparently quite healthy, and galvanism seemed clearly indicated in the case. It was therefore strongly recommended to apply it for some time by one of Pulvermacher's chains, but this failed, when it was continued by means of a metallic brush for a much longer period, but there was not the least return of the voice. Knowing that the alternation of topical remedies often proved efficacious in the treatment of chronic inflammation of mucous passages, they were prescribed during the whole of this time, but neither of them, combined with the former, produced any good effect. The cords were then faradised by means of Mackenzie's electrode, when after very few applications of the electro-magnetic current the voice was partly restored, but as a very harsh "croak" at first, and very monotonous. She was asked to sing over a scale of music, but every note was pronounced in the same tone, and she could not modulate her voice either piano or fortissimo. After the current had been repeated at gradually lengthening intervals, however, the voice was permanently restored, and now she speaks in a clear and natural tone, which had been lost for nearly five years. She was seen a few weeks ago, and I heard from her own lips that the cure had been permanent.

Remarks.—This patient, anxious to regain her voice, had previously given everything prescribed for her, both local and constitutional, a fair trial. Tonics and zinc pills were persevered in for a very long time, as well as the inhalation of vapours impregnated with different volatile principles. Powders were introduced by insufflation, and this again followed by various escharotics, but without the least benefit resulting until the vocal cords were faradised, which proved there had been no structural disease, but that the case resolved itself into one of functional aphonia or vocal weakness. The case requires no further comment, but the superiority of the internal method of faradisation must certainly be admitted.

Newcastle-on-Tyne.

CASE OF ENTERO-EPIPLOCELE; OPERATION AND RECOVERY.

BY J. NOBLE BREDIN, L.R.C.S.I., &c.

ON Sept. 4th I was sent for to see a man aged fifty-seven, of very robust constitution. On examination I found a swelling in the right groin, hard, without fluctuation, and with comparatively little tenderness. Having learned that a small nodule had been there several years, it at once occurred to me this was an enlarged gland brought on by overwork, patient being a hop dryer, and hopping just then being in full swing. He was now about resuming his occupation. I ordered him to bed, and he obeyed after much remonstrance. No history of anything coming on suddenly. All I could learn was that the swelling became larger four days previously. I then concluded it was a femoral hernia, and tried the taxis, using much caution, but without effect. At 6 P.M. the same evening I put him under the influence of chloroform after a prolonged struggle, at the same time being very careful as to manipulative measures, feeling, I must confess, rather dubious about the case. This was also without success. On the following morning patient did not seem any worse. During the time that had elapsed, now five days, no sickness, no hiccough, not even a bad symptom showed itself to give a clue to the case. I now obtained the assistance of Mr. Harris, surgeon to the West Kent Hospital, Maidstone, who fully concurred in all that was done.

We forthwith placed him under the influence of bichloride of methylene, although I must say I look on this anæsthetic as being far inferior to chloroform. Our patient inhaled a very large quantity before complete insensibility supervened. Manipulative measures were again tried, but in vain. Lister's operation was then performed, and after dividing the constricting tissues no reduction could be effected. The sac was now opened. We then found the omentum had been pushed down before the intestine. This was ligatured about half an inch from the end, cutting off the omentum, reduction taking place immediately. The wound being stitched and a bandage applied, I gave him a quarter of a grain of morphia, with directions to repeat the dose in four hours, also one tablespoonful of brandy in milk every three hours, together with beef-tea in the interim. Patient passed a good night very comfortable and free from pain. I saw him four times next day to watch the effects of the morphia, which I still continued. Patient went on without interruption, not an untoward symptom or even any pain, still going on with the morphia at intervals, until the expiration of seven days. The bowels not being relieved, I ordered two teaspoonfuls of castor oil every two hours *ad effectum*. This produced a very decided change for the better, the motions being perfectly natural, and passed without pain. On the eighth day I ordered him one pint of stout daily, directing his wife to send each day to my house for some dinner, to which he did ample justice, together with one pint of bitter beer. Wound healing and looking healthy. Dressed with carbolic acid (1 to 20). He was up and about with a truss in forty-six days after the operation.

Remarks.—Morphia seemed to me to be the sheet anchor in this case, equalising the system, thereby preventing all pain, and keeping all inflammatory action in submission. Consequently no sickness or nausea occurred, such as I have seen follow from methylene.

ST. GEORGE'S HOSPITAL.

[SKIN DEPARTMENT.]

CASE OF BROMIDE ERUPTION.

(Under the care of Dr. CAVAFY.)

THE following notes were taken by Mr. Alexander, clinical clerk.

Edward B——, aged fourteen months, was first seen at the hospital on March 17th, 1881. The child had whooping-cough, from which, according to the mother, he had suffered for five months. Six weeks before he was attacked with convulsions, which were at first very frequent. They gradually diminished and subsided in a fortnight under treatment by bromide of potassium, which the mother stated was at once ordered by the medical man who saw the child, and continued for a week after the fits had ceased. Various medicines had been given for the whooping-cough, and the last prescription (which the mother brought with her) contained bromide of potassium, tincture of belladonna, and juice of conium. The daily dose of bromide contained in this last mixture was four grains, and the medicine had been taken for about fourteen days. Four or five days before the date of application an eruption appeared on the face of the infant, which quickly reached its present condition—viz., on the right cheek there were four raised nodular patches and five similar ones on the left cheek. The nodules were large, circular or oval in outline, prominent, with a rounded surface, and sharply circumscribed. The largest measured an inch in its longest diameter, the others varying from a quarter to half an inch, and they projected fully a quarter of an inch above the surface of the skin at their central parts. They felt very tense and slightly elastic, and appeared to be tender, as the child cried when they were handled. The surface of each little tumour was covered by smooth epidermis, on which no plugged and dilated orifices of sebaceous glands could be discovered on careful inspection; the surface, however, had a somewhat coarsely granulated aspect, owing to the presence of very numerous subjacent little spheres varying in size from a mustard seed to a millet seed. These were of a milky or turbid yellowish aspect, and were imbedded at various depths in the matrix of the nodules; this was of a bright crimson-red colour, which disappeared very incompletely on pressure. The apex of each tumour was covered by a small, thin, black crust of altered blood, which was situated under the epidermis. The greater number of the nodules were studded close to each other on each cheek, and all were sharply marked off at their edges from the perfectly healthy skin on which they were seated. A few isolated red papules, of which the largest was the size of a hemp seed, were scattered over the face, chiefly on the forehead; all the remaining skin of the body was unaffected by any eruption.

No treatment was adopted beyond stopping the bromide, and in a week (March 24th) the black scab above described was found to have extended nearly over the whole surface of the nodules, from which the congestive and hæmorrhagic redness previously noticed had quite disappeared, although their size was not appreciably diminished; no trace remained of the smaller papules. The child was not seen again.

Remarks by Dr. Cavafy.—A variety of eruptions due to bromides have been described, of which an excellent account will be found in the paper on Medicinal Eruptions by Dr. Van Harlingen, of Philadelphia, in the *Archives of Dermatology* for last year. The above case resembles the "little tumours formed by small groups of very indolent, acne-like pustules" described by Voison (1868), and the similar cases published by Dr. Cholmeley (1870), Dr. Lees (1877), and others. A point of some pathological interest in my case is the great congestion and hæmorrhage into the nodules, as shown by the very incomplete disappearance of the redness on pressure, and especially by the formation of the thin sub-epidermic black crust of altered blood; this, no doubt, points to an affection of the minute bloodvessels of the skin, similar to that described by Dr. Thin (Medical and Chirurgical Transactions, 1879), as occurring in iodide eruption; no such affection, however, is noted by Neumann in his account of the microscopical appearances of bromide rash. In my case no iodide was taken to my knowledge, but it may very possibly have formed an ingredient in the medicine administered for the convulsions, of which I did not see the prescription; it is worth remembering that the eruption may appear several days after iodides or bromides have ceased to be taken. Dr. Van Harlingen prefers Dr. Duhring's name for this affection, "circumscribed phlegmonous dermatitis," to that of "confluent acne" proposed by Dr. Cholmeley. It is perhaps more accurate; but I think the simpler term bromide eruption sufficiently meets all the necessities of the case.

GENERAL HOSPITAL, BIRMINGHAM.

SARCOMA OF RIGHT OVARY; PROTRACTED METRORRHAGIA; REMOVAL OF BOTH OVARIES; RECOVERY.

(Under the care of Dr. Malins.)

For the following notes we are indebted to H. J. Borling, M.B.

M. A. B——, aged thirty-four, single, was admitted on February 11th, 1881, and gave the following history. For nearly two years past she had had profuse discharge at the periods, sometimes lasting for three or four months without cessation. She had not much pain, no difficulty in defecation or micturition, though there were occasional diarrhœa and frequent inclination to pass water. She had kept her bed for two months before admission, and had become extremely pale and feeble.

In July, 1880, the patient consulted Dr. Malins, but as she refused to submit to an examination she was not prescribed for. Subsequently she came under the care of Mr. Ker, who, in conjunction with Dr. Malins, dilated the os uteri, and examined the interior of the cavity. No remedies of any kind, either locally or by the mouth, appeared to have had any influence in abating the persistent discharge.

On admission she was very pallid and anæmic in appearance. On pressing the hand in the hypogastric region a distinct and hard tumour could be felt; per vaginam the pelvis was found to be filled with a hard mass, which moved with the uterus, and appeared to be part of it. The sound passed two inches and three-quarters apparently into the tumour, which could just be made to move independently. There was no albumen in the urine, and the other internal organs were healthy.

In consideration of the extremely weak condition of the patient it was considered justifiable, after consultation, to remove the ovaries, in order to stop the continued drain and give the patient what seemed to be her only chance of recovery. Accordingly, on March 2nd she was placed under ether, and an incision was made in the median line, under strict Listerian precautions; the left ovary was removed, and its corresponding ligament, being tied in two divisions by fine silk, was cut away with scissors. The right ovary was found to be a large mass closely wedged in the pelvis, occupying the hollow of the sacrum and jamming the uterus to the left. It could not be moved until two cysts on its surface were tapped with a trocar and emptied—one containing bloody fluid, the other serous fluid, together to the amount of six ounces. With strong cyst forceps in one hand and the two fingers of the opposite hand pushing from the vagina, the ovary was brought out of the pelvis, and the short broad pedicle was firmly tied in three portions with fine silk. The wound was dressed for the first time on the fifth day, and the patient made an uninterrupted recovery, being discharged cured on the twenty-fifth day after the operation.

The tumour was examined by Dr. Mouillot, who reported as follows:—"It is an oval growth, with cysts at the surface, enclosed in thick walls; the centre of the solid part is firm, with bands of connective tissue running through it, the external portions being softer. Weight 18 oz. Microscopically it presents the appearance of a spindle-celled sarcoma.

Remarks.—The principal points of interest in this case are the difficulty of diagnosis from uterine fibroma, and the nature of the growth; it would be rightly classed as a cysto-sarcoma, a rare condition in the ovary; the history dating back for two years probably indicates the existence of the growth for the same length of time, so that though microscopically it is described as a sarcoma, yet clinically it can hardly be considered a malignant growth, and recurrence is improbable.

TOXTETH PARK INFIRMARY.

INTERNAL URETHROTOMY.

(Under the care of Dr. Lyster.)

H. B—— was admitted on Nov. 18th, 1880, suffering from a bad stricture of eight or nine years' standing, for which he had been treated off and on during all that time. A month before his admission he went to a medical man who, failing to pass a catheter, advised him to go to the hospital. As he was not suffering from any urgent symptoms when admitted, he was ordered to bed for a day or two, previous to any attempts being made to pass a catheter. Hot baths and morphia suppositories were administered during that time. His water dribbled away from him continually, so that he was obliged to keep his penis in a urine-glass night and day. The urine was very ammoniacal, and at times contained a great quantity of mucus. The day after admission an attempt was made to pass a catheter, but it was unsuccessful; not even the filiform bougie could be passed. Dr. Lyster determined to perform internal urethrotomy as soon as the guiding-bougie could be passed. Attempts were made several times after this at intervals, but always unsuccessfully until Dec. 1st, when the patient had a severe rigor some time after coming out of the bath, followed by several others at intervals during the day. This was the precursor of a very severe attack of pyelitis, which so told upon a constitution previously debilitated as at one time to place his life in great danger. But with the aid of hot-air baths, dry cupping, diaphoretics, and diluent drinks, supplemented by the infusion of buchu and nitric acid as medicines, he got over this.

On January 5th, three weeks after the disappearance of pus from the urine, and when he had regained his strength a little, Dr. Lyster again attempted to pass the filiform bougie, and to his surprise it went in without much difficulty. It is worth noting that during the time the patient's urine was loaded with pus and the febrile disturbances great, the flow of urine was less impeded than it had been previous to the attack. Having passed the bougie, the grooved director was then screwed on (Maisonneuve's instrument was used), which went in without difficulty; after which the urethrotome was passed and the stricture divided. A No. 10 catheter was then passed with ease, and allowed to remain in some time. Eight grains of quinine were given, and he was put to bed. For some days after the operation he had no control over his bladder, his urine passing away from him involuntarily, but he gradually gained power, so that when he left the hospital he was, to use his own words, "as well as ever." When he left on February 16th he was passing a No. 11 bougie daily, and otherwise in excellent health.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Peculiar Warty Growths on the Face. — Experimental Inquiry on Artificial Respiration in Stillborn Children.

THE ordinary meeting of this Society was held on the 26th ult., Dr. Barclay, President, in the chair.

The first paper read was one by Dr. THIN on "Peculiar Warty Growths upon the Face," of which the following is an abstract. The paper described the case of a young unmarried woman, twenty-one years of age, whose face had during the course of three years become covered with a great number of dark-brown, smooth, flat, papular growths, averaging about the twelfth of an inch in diameter. On some parts of the face these growths were so thickly set that they had coalesced into small patches. The whole face was covered, but the scalp and neck were free. They began on the skin, and gradually showed themselves on the upper part of the face. With the exception of the backs of the hands, on which they had begun to show themselves after they had existed two years on the face, no other parts of the body were affected. They produced no symptoms, and the skin surrounding them was healthy. Their number was so great that the face was nearly as much disfigured as if it were the seat of an extensive small-pox eruption. Microscopical examination of one of the growths showed that the affection had its seat in the epidermis, and might be considered as a rare variety of warts. The papillæ were much elongated, and the interpapillary epidermic projections correspondingly deep and wide. The papillæ contained a considerable number of exudation cells; there was very slight cell exudation in the superficial vessels immediately under the epidermis, and the connective tissue of the cutis was healthy. Some features in the case suggest an increase in the number of the growths by a process of auto-inoculation. None of the growths had disappeared, and they had resisted a variety of local and general treatment.

Then followed a paper by Dr. F. H. CHAMPNEYS, entitled, "Second Communication on Artificial Respiration in Stillborn Children: the Expansibility of various Parts of the Lungs. An Experimental Inquiry." The question dealt with is, "which part of the lungs of a child which has been subjected to various methods of manipulation with the view of artificial respiration is most frequently expanded, and which most frequently unexpanded?" An answer is attempted by careful study of the lungs of children thus manipulated, who have, however, breathed. The material was furnished by twenty-six fœtuses, the results of the experiments having already been laid before the Society. Of these twelve only could be utilised for the present inquiry, all those in which direct inflation had been used being necessarily excluded. A table is given in which the first column refers to the number of the experiment, the second to the methods of manipulation employed, the third to the amount of air charged, the fourth to the conditions of the thorax as shown by dissection. An analysis is given of thirty-six cases selected from Schmidt's 101 cases (Neue Versuche, &c. Wien, 1806); and of sixteen cases selected from Joerg's nineteen cases (De morbo pulm. Lips. 1832, and Die Fötuslunge Grimma, 1835). The results of this analysis are stated as follows:—In children which have died soon after birth: 1. The right lung is usually better expanded than the left. 2. The anterior surfaces more than the posterior. 3. The lower lobes are the parts most often expanded. 4. The right middle lobe is usually well expanded. 5. The part of the left lung corresponding to the right middle lobe is often better expanded than the rest of the left lung. When the right middle lobe, on the other hand, is ill expanded, the corresponding part of the left lung is often unexpanded also. It is remarkable that in children who have breathed naturally, the bases are so often unexpanded; this seems to correspond with the fact that the characteristic of feeble breathing in infants is feeble descent of the abdominal viscera, betokening feeble descent of the diaphragm. The author concludes, from his experiments, that in children which had been manipulated by the various efficient methods of artificial respiration: 1. The right lung is more usually expanded than the left. 2. The anterior surface than the posterior. 3. The apices of the upper lobes are often unexpanded. 4. The anterior inferior borders the same. 5. One of the places of selection for atelectasis is a strip running vertically along the angles of the ribs on each side of the spine. 6. The patches of expansion or atelectasis, when considerable, are not confined to lobes, nor bounded by fissures. 7. The last circumstance is not due to obstruction of the bronchi. 8. The spots of predilection for expansion or atelectasis underlie the region of greatest and least movement of the chest walls.—The PRESIDENT remarked that the simplicity of the conclusions arrived at were great proof of the value of the philosophical argument in the paper. — Dr. DOUGLAS POWELL, without wishing to anticipate the author's further contribution to the subject, thought it would be of interest to learn in which method of artificial respiration there occurred mediastinal emphysema and pneumothorax, which one was hardly prepared to hear could follow upon the use of the ordinary methods. The parts of the lung expanded corresponded tolerably closely to the attachments of the muscles on which traction was used—e.g., the pectorals. Another part expanded was the anterior inferior angle, which is the weakest part of the lung and the first to suffer collapse after absorption of pleural effusions. Again, the posterior parts which remained unexpanded in the child when the diaphragm was not used are those which are least able to expand. He could hardly explain the non-expansion of the apices, but then conversely it was not easy to account for the ordinary expansion of these parts. The scaleni muscles may exercise some traction on them, and perhaps the descent of the diaphragm also; but in Silvester's method, although the arms are drawn fully upwards, yet Dr. Champneys had found the apices commonly collapsed. The paper was of great practical value, although but a record of experiments. — Dr. REGINALD THOMPSON suggested that besides the possibility of rupture of the lung, the mediastinal emphysema and pneumothorax might be produced through the tracheal wound. Wilks and Moxon described two cases of sudden dyspnœa and death from collapse of the lungs following tracheotomy, and Dr. Thompson had seen a case of the same kind, where, however, the pneumothorax was unilateral, the lung on the opposite side being universally adherent. The portions of lung which Dr. Champneys found to be expanded were just those selected under other conditions—e.g., in acute over-distension of the lung (wrongly termed emphysema), sometimes occurring in a few hours in cases of acute œdema or rapid pleural effusion, where sudden and violent dyspnœa arises. The anterior and lower portions of the lung were drawn upon in such cases, and in becoming over-distended with air yield a very resonant percussion note, whereas the portion in the spinal fossa does not expand.—Mr. SAVORY suggested the importance of determining the degree to which the areas of expansion were due to the inherent qualities of the lung as well as extraneous causes. When a lung is inflated outside the body it expands unequally, and there might be anatomical conditions which determined this and the results of Dr. Champneys' experiments. The greater expansion of the right lung might be explained by the larger size of its bronchus, and the unequal expansion to variations in the degree to which different parts of the lung are developed, or the accidental accumulation of mucus in the air-tubes might produce such irregularity.—Dr. ROPER, finding it difficult to understand how pneumothorax could be produced by the gradual admission of air, suggested that there must be undue violence in the method to produce it. He had known rupture of the liver to occur from too violent measures. Perhaps the difference between the fœtal and adult lung had something to do with the production of the pneumothorax.—Dr. O'CONNOR in two cases of attempted inflation of the lungs in the stillborn had found only the anterior portions of the lungs expanded. In each case the artificial respiration was conducted with the child lying on its back, and he thought the position of the body might have some influence on the result, the absence of air in the dependent parts of the lung being possibly due to gravitation of mucus.—Mr. BARROW suggested that the emphysema and pneumothorax were produced in the expiratory movement, having found such emphysema in cases of children who had been overlain, when he attributed it to the pressure on the chest, causing rupture of the air vesicles. —The PRESIDENT asked in what respect insufflation differed from the other methods in its effect on the lung.—Dr. CHAMPNEYS, in reply, said that by insufflation the lungs could be perfectly inflated, in one or two cases to the extent of rupture. Owing to the small amount of material at his disposal he had practised all the methods in each case, but he had no doubt that it was in Schultze's method that the mediastinal emphysema and pneumothorax occurred. As he had shown in his previous paper, that method is a violent one, causing even a temporary over-inflation as shown by the manometer; and in performing it a peculiar sucking noise is produced at the root of the neck by the air finding entrance from the tracheotomy wound beneath the cervical fascia into the mediastinum. He had proved this by laying open the cervical fascia (without opening the trachea); then, placing some injection material in the wound and performing artificial respiration, the material disappeared, being forced into the mediastinum. Dr. Powell's explanation of the expansion of the anterior portions of the lung being related to the attachment of the pectoral muscles was good. He could not account for the non-expansion of the apices, except that the lower ribs move more than the upper; certainly it could not be from accumulation of mucus. Nor could mucus plugs explain the unequal expansion entirely, for the unexpanded parts were not limited to particular lobes. No doubt there were differences in the fœtal and adult lung, but the lung of a child which had never breathed was expanded with the greatest facility. Even a few breaths largely increase the tenacity of the lung, probably because its expansion allows of greater influx of blood and increased nutrition. The rapid improvement in the nutrition was evidenced by the rapid growth of the rib cartilages after birth. In his former communication he had noted that he had not found the portion of the body to influence the degree to which the lung is inflated.

Mr. CLEMENT LUCAS showed an infant the subject of Desquamative Syphilis of the Tongue, to which M. Parrot had recently drawn attention. The child was three months old, and began to suffer from an eruption on the nates at the age of one month. Later there appeared two small red patches on the tongue; these patches increased in size, and the interval between them became coated into thickened epidermis, resembling thrush, some varieties of which were, he supposed, of this nature. There was a clear history of syphilis in this case, the parents being two years married, and the mother showing syphilitic manifestations four months after marriage, and a previous child died a few weeks after birth, having an eruption on the nates.

MEDICAL SOCIETY OF LONDON.

Chancre on the Lip.—Evil Results of Partial Operation in Cancer of the Breast.—Acute Prostatitis.

AT the meeting on April 11th, Dr. Broadbent, President, in the chair,—

Mr. ED. OWEN exhibited a patient, a widow, with a Hard Chancre upon the Lower Lip. There was induration of the submaxillary lymphatic glands, and the chest and arms were covered with a papular syphilide. There had been no sore-throat, nor pains in the forehead or tibiæ. From the evidence before him he concluded that the sore had originated from syphilitic virus inoculated from mucous tubercles in the act of kissing. The patient had been taking drachm doses of the solution of perchloride of mercury twice daily for a fortnight, and the induration was steadily diminishing.—Mr. MASON referred to an instance where a man had been twice operated on by others for cancer of the lip; but in his opinion the induration was of syphilitic origin. He did not consider that the presence of a hard chancre in an extraordinary situation was very uncommon, and referred to cases which had been under his care.—Mr. WORDSWORTH said it was more difficult to distinguish a soft sore upon the eyelid, of which he had seen several cases.—Mr. HENRY MORRIS related the case of a young man who had been under his care for a chancre of the lip contracted from a female patient with a guttural voice and ulcerated tongue. The case recovered under mercury.

Mr. GEORGE LAWSON read a paper "On the Evil Results which follow Partial Operation in Cases of Cancer of the Breast." He stated that in the cancer wards of the Middlesex Hospital patients were admitted from all parts, and allowed to remain for life. Opportunities were thus afforded for studying not only the varieties of cancer, but also the various methods of treatment adopted by surgeons for the removal of the disease. He read the history of two patients who had been admitted into this hospital under his care, suffering from cancer of the breast, and in each of whom two partial operations had been performed. In each case the primary nodule had been excised without removing the breast. A recurrence of the disease soon took place, and the recurrent growth in each patient was excised, but the breast left. Mr. Lawson expressed his opinion that to do a partial operation and remove the tumour only, and leave the breast was not only useless, but worse than useless. One operation stimulates the growth of the cancer, and hastens the progress of the disease instead of retarding it. The delay of efficient treatment which such a partial operation causes is also very prejudicial, as the recurrence of the disease, which is almost certain to take place, is usually very extensive, and frequently such as to forbid any further operative proceedings. "I am convinced," he said, "that in all cases of scirrhus of the breast which admit of operation, even though the growth be no larger than a chestnut, and be placed at the edge of the gland, the whole breast should be removed, and that rather than perform a partial operation it is better to allow the disease to run its course."—The PRESIDENT remarked that the paper opened up the old question as to whether cancer was of local or constitutional origin.—Mr. MASON asked if the author would remove the whole mamma if the disease were situated well to one side of it. Few cases came back to him for secondary operation, and he would ask what became of all the cases operated on. Did they relapse or get well? Sir W. Fergusson had a case where there had been no recurrence ten years after operation.—Dr. GILBART SMITH asked whether in a case of cancer implicating both breasts Mr. Lawson would remove the whole of each organ.—Mr. OWEN asked the author for his opinion upon repeated operations in recurrent scirrhous infiltration. He mentioned the case of a woman who had been operated on no less than four times by himself and by Mr. Lynch once for return of the growth in the cicatrix and the axillary glands. It was now about eight years since he had performed the first operation, and more than a year since the last; to all appearance the patient was now perfectly well.—Mr. LAWSON, in reply, said that in his opinion it was expedient to remove the whole of the breast even when the malignant infiltration invaded it but partially. His experience was that patients operated upon continually returned for further advice. In the majority of cases there was recurrence. He had never had occasion to operate on a patient with each breast affected, but he had removed a scirrhous mass from a woman on whom Mr. De Morgan had, many years before, excised the other gland for cancer, and who even now continues well. He thought that in many cases, such as that reported by Mr. Owen, everything was gained by repeated operation, but there were others in which the local and constitutional conditions precluded further operative interference.

Mr. REGINALD HARRISON, of Liverpool, read a paper on Acute Prostatitis, of which he distinguished two forms—the follicular and the parenchymatous. The former was most frequently seen as a complication of gonorrhœa, and suppuration was exceptional. In reference to suppuration and the insusceptibility of the muscular element of the prostate to inflammation, Bumstead's observations apply accurately to follicular prostatitis. He says:—"There is never at the outset an abscess of considerable size. Such occurs only by the coalescence of a number of small ones seated in the follicles. Meanwhile the muscular tissue which constitutes so large a portion of the prostate gland is unaffected, except that it is in a constant state of contraction, thereby inducing urethral and rectal tenesmus." The other form of prostatitis, the acute general or parenchymatous, was a much more serious condition, as the whole mass of the prostate, becoming inflamed, tended to suppurate rapidly. Here, unless the treatment was prompt and decisive on the first appearance of fluctuation, as detected by rectal examination, the most serious results, both to structure and life, were likely to follow. This form of prostatitis was rare, and few examples were recorded, but sufficient to distinguish it. It was usually accompanied with more or less serous, or even purulent, infiltration of the structures around the gland, a condition which had been described as periprostatitis, which he had only seen as secondary to acute prostatitis. This form of the affection was only observed in individuals of either much deteriorated constitutional powers, or whose urinary organs had been more or less damaged by long-standing obstructive disease. Some instances he had observed were apparently due to a previous state of tuberculosis of the gland. The occurrence of suppuration was to be carefully looked for, as the spontaneous escape of matter in such directions as the rectum, bladder, and peritoneal cavity was likely to be much more detrimental than the opening which the surgeon would afford. Gangrene of the prostate as a consequence of inflammation was referred to as occasionally happening, and two illustrations of this were given, one following lithotomy in an unhealthy subject. Inflammation and suppuration round the membranous portion of the urethra, not uncommon in gonorrhœa and phlebitis of the vessels forming the prostatic tissues, simulated prostatitis. The former presented many points of resemblance to inflammation of the gland, but distinguished by perineal tumefaction and digital examination of the rectum. Particulars of two cases of blocking of the dorsal vein of the penis followed by an extension of the blocking to the prostatic tissues were briefly narrated. In the treatment of prostatitis the local abstraction of blood and hot applications were most efficacious at the outset of the disease. Hot enemata, as advised by Guthrie, and the injection of hot water into the urethra by means of a douche were also recommended. Mr. Harrison was strongly opposed to the use of purgatives, as causing pressure to be exercised on the inflamed prostate by the levator ani muscle, and being opposed to the principle of securing rest in the treatment of an inflamed part. The occurrence of suppuration was to be carefully looked for, and in reference to this point he was disposed to formulate a conclusion to the effect that any formation of matter which was not to be detected by the finger in the rectum might with safety be left to evacuate spontaneously; but that when fluctuation was in this way detected, a perineal incision became imperative Incision was preferred to puncturing the abscess with a trocar by the rectum. Stress was laid upon the great importance of rectal examination in all these cases, or in those simulating it, and for this purpose should the pain or tension be so great as to interfere with the thoroughness of the procedure, the use of an anæsthetic was advised. A brief reference was made to abscess of the prostate unattended with the ordinary symptoms, such as the case recorded by Dr. Pitman of St. George's Hospital, where this happened as a sequence of gonorrhœa, and terminated in the death of the patient. An occasional consequence of follicular prostatitis was a more or less permanent dilatation of the follicles, and this was believed to be a not uncommon source of prostatorrhœa—a complaint well described by Professor Gross, and often very difficult to cure.—Mr. LAWSON mentioned the case of a man who had pain on micturition and defecation, found to be due to an abscess, which was successfully evacuated by puncture through the rectum.—Mr. H. MORRIS referred to a similar case, in which the chief sign was a painful diarrhœa, which turned out to be associated with prostatic abscess. This was treated by incision through the perineum. The abscess did not seem to be in communication with the urethra. He considered it impracticable to distinguish between a follicular and parenchymatous abscess. Many such abscesses started in follicular inflammation and suppuration; and he thought that in some cases the condition was associated with sudden suppression of the seminal discharge.—Mr. TEEVAN agreed that it was hard to discriminate between a follicular and parenchymatous inflammation. He was in the habit of applying solid ice to the rectum in the early stages of inflammation, and he related two cases in which the inflammation was due to sudden attacks of cold.—Mr. OWEN asked the author if he would not prefer to open a prostatic abscess which lay quite close to the rectal mucous membranes through the bowel rather than through the perineum. When, as sometimes happens, the surrounding tissue is healthy or indurated, it might take weeks before such a localised abscess would burst into the urethra. In his experience acute prostatitis with suppuration attacked the strong and healthy rather than the tuberculous subject. From the analogy afforded by the relief given in acute orchitis he suggested that puncture of the acutely inflamed growth might give speedy relief, and obviate the future formation of abscess.—Mr. MASON had practised puncture of the acutely inflamed prostate with manifest advantage.—Mr. GOODSALL said that in his experience prostatic abscess was rare, and when seen was usually the result of gonorrhœa. An enema was valuable at the outset of treatment.—The PRESIDENT, though he had never seen a case of prostatic abscess, had seen several instances in Ricord's clinic in which suppuration had been diagnosed in the glands of Cowper.—Mr. HARRISON, in reply, said that when the abscess seemed close to the rectum the incision might be made through the bowel. He admitted that it was often difficult to diagnose the inflammation beginning in the follicle from that starting in the parenchyma. The former was of much more common occurrence, and general suppuration within the capsule was no doubt rare. The causes of inflammation were various, though the gonorrhœal poison was most frequent. There was an analogy between acute inflammation of the prostate and that of the testis, and in certain cases multiple puncture may be performed, though he had no experience of it. When inflammation was followed by tumefaction in the perineum, such abscess as a rule had no association with the prostate.

The meeting then adjourned

Reviews and Notices of Books.

Grundzüge der Physiologie des Menschen mit Rücksicht auf die Gesundheitspflege. Von JOHANNES RANKE, Prof. au der Universität zu München. Fourth Edition. 274 Woodcuts. Pp. 1086. London: Williams and Norgate.

PROFESSOR RANKE'S work is one of the great German text-books on Physiology, and takes equal place with those of Müller, Ludwig, Otto Valentin, Otto Funke, Hermann, Wundt, Budge, and Landois. Each of these great works has an individuality of its own, and Ranke's treatise holds no mean position amongst them. For breadth of view and general knowledge none surpass John Müller's classical book, and we should be inclined to place this at the top of the series, though now, of course, it is antiquated. Many parts may, however, still be read with advantage by the teacher if not by the pupil. Otto Funke's, perhaps, comes next, though it is heavy reading after Müller. Its enormous paragraphs, sometimes extending over two or even three pages without a break, are very trying, though they are full of matter. The account of the senses, and especially of the eye, is remarkably complete and full, occupying, in fact, nearly one-sixth of the whole work. The death of the author prevented the fifth edition from being carried further than the first two parts, but a new edition has been recently issued, brought up to the present day. This constitutes a very excellent text-book for the lecturer, but is hardly serviceable to the student. Valentin's treatise is pleasantly written, was well translated by Dr. Brinton, is excellently illustrated, and contains many facts that when the work was issued were original, and its short and pithy sentences strongly impress themselves upon the mind; but it is now far behind the time in every branch of physiology. Wundt's Physiology is a sound work, but is only a part of an encyclopædia, many points being relegated by the author to his treatises on Medical Physics and Physiological Psychology. Of Hermann's work we can only say that it is uncommonly tough reading — in fact it is rather a memorandum-book for the lecturer than a text-book for the student. The original has faults of arrangement that even Dr. Gamgee's abilities have failed to remove in translation. The introduction of the authority for each statement in brackets is destructive to all continuous reading. The perpetual occurrence of parentheses, the alternation of large type and small type, and the harsh dogmatic style, are all features that render it unsatisfactory for the student. The chemical introduction has graphic formulæ that make one wonder whether any mortal has achieved the task of fixing more than one on his memory.

Landois' work is a very successful one, and deserves translation. It is full, accurate, not too lengthy, excellently illustrated, and well adapted for the practitioner. A due proportion is maintained between the different parts, and both the practical and theoretical side of physiology are well represented. It has the advantage of giving all recent work clearly and intelligibly, and rarely deals with mathematical symbols.

The distinguishing characteristic of Ranke's work is the pains he has bestowed upon that side of physiology which is of practical utility and can be applied by the physician. Though Funke's work is double the size of that of Ranke, the latter devotes nearly twice as much space to the consideration of the subject of nutrition, including the different kinds of food, the action of the digestive fluids upon them, the structure and movements of the intestinal canal, and the balance of the ingesta and egesta. Ranke bestows much attention upon the blood, upon the subjects of respiration, ventilation, and the urine, and generally upon the application of physiology to hygiene. On the contrary, the nervous system and the special senses are very shortly discussed, and development is practically omitted. There are good sections appended to each chapter on the manipulation of physiology. In these the student will find the best and most recent methods of testing for the various normal and abnormal constituents of the urine, the tests for the bile and for the purity of milk, and modes of applying electricity.

There are a few points to which we should like to call attention in Professor Ranke's work. In speaking of the blood, he makes a statement, which is probably true, to the effect that in the new-born infant it amounts to only 5·2 per cent. of the weight of the body, instead of 7·7 per cent., as in the adult, which may account for the serious effects of small losses of blood in young children. He has found also that fat, well-fed persons have but little blood comparatively, which might not be expected. Strong muscular exertion diminishes the quantity of blood, and it diminishes in the course of many diseases; yet its normal proportion, as his experiments show, is rapidly regained—perhaps owing to the great diminution of the secretions on the one hand, and on the other to the powerful current that sets in to the blood from the tissues.

Ranke has made some interesting researches on the distribution of the blood in the system, and considers that the whole mass may be divided into four parts—one of which is contained in the heart and large vessels, one in the liver, one in the quiescent muscles, and one in all the remaining organs put together. Great variations occur at different times in accordance with the functional activity of the several organs, and no better instance of this can be given than in the case of the muscles of the frog, which when exhausted by long-continued exercise, contain 47 per cent. more blood than when in the quiescent condition. As a consequence blood being withdrawn from the general system the activity of the secreting glands is considerably lowered, and the quantity of urine and bile secreted is diminished.

All the sections on nutrition are interesting in this work. Speaking of the influence of flesh diet on the excretion of urea, he states that whilst the average healthy man eliminates 37 grammes per diem, which proceeds chiefly from the disintegration of albumen, he has been able by taking an excess of animal diet to raise the quantity to 86 grammes per diem, or 1345 grains. Ranke's observations on himself whilst fasting showed, on the other hand, that on the second day of complete abstinence, the quantity of urea eliminated was only 17 grammes, or 260 grains, a very small amount for a man of large frame, weighing about 200 lb. Ranke shows very clearly that for the absorption and application in the economy of non-nitrogenous food, the presence of a certain amount of albumen is absolutely necessary—a point that is now well-known, and always mentioned in text-books, but which he, with Bischoff and Voit, was the first to ascertain by direct experiment.

Professor Ranke mentions the chief centres in the spinal cord and medulla oblongata, and states also over what functions they preside; but we think he should have mentioned the afferent and efferent fibres in each instance. The views of Meynert on the structure, and those of Hitzig and Ferrier on the physiology, of the brain, are given fully enough. Upon the whole, the work seems to us to be sound, and it certainly contains many facts which are the outcome of Ranke's own observations. The illustrations are 274 in number, and though not particularly finished specimens of wood engraving, are useful additions to the text.

Dysmenorrhœa. By Heywood Smith, M.D. London: J. and A. Churchill.

Dysmenorrhœa is treated of in this work as ovarian, tubal, uterine, that arising from diseases of the broad ligaments, and from general diseases. As painful menstruation is or may be present with most diseases of the uterus, broad ligaments, and ovaries, it follows that most of these diseases would have to be noticed under such a classification. And this we find the case in this little work of 122 pages. In the preface the author states that the work was "written originally with an object other than publication." It is a pity he did not adhere to his original intention. There is, however, something new in the work. In a note it is stated, "On January 20th the author performed an operation which he believes is entirely new, in a case of retroflexion, where the utero-sacral ligaments were shortened and very tense. The operation consists in passing a knife per rectum, and slightly cutting through the ligament near its sacral origin." We readily allow the claim made by the author; but while we grant that he is the first, we may be permitted to express a hope that he may be the last to perform an operation of this nature.

A Treatise on the Diseases of the Ox. By John Henry Steel, M.R.C.V.S., &c., late Demonstrator of Anatomy at the Royal Veterinary College of London. London: Longmans, Green, and Co. 1881.

A really good work on the diseases of cattle has not yet been produced. Youatt's treatise on the ox was undoubtedly a great advance on anything that had been previously published, and up to the present day it has been pretty well the standard book on cattle disorders. Other works have been issued since it first appeared, but they have generally been written for amateurs, and aimed at teaching every cow owner how to minister to the ailments of his animal, rather than advancing bovine pathology. Mr. Steel's "Diseases of the Ox" does not belong to what might be designated the popular class of animal-doctoring books, as he has evidently aimed at something better, and has attempted to produce a work which might be useful to the student, or even to the veterinary practitioner, as a handy work of reference. In this he has very well succeeded, considering the materials at his hand, and we have a book which fairly represents the knowledge possessed of the maladies of the bovine tribe in this country. The author does not pretend to offer anything in the way of novelty, but rather to give a summary of the various notions which prevail among those who have specially devoted themselves to this branch of veterinary medicine. To the medical man who may have occasion to deal with the subject at any time, the book will be found better and more reliable than any other we are acquainted with in the English language, and more especially as it gives at the end some bibliographical notes which will assist the inquirer to extend his knowledge further.

THE

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, APRIL 28TH.

DR. ACLAND, PRESIDENT, IN THE CHAIR.

Dr. PYLE, pursuant to notice, asked the President whether certain business referred to in the minutes of the Executive Committee did not more properly belong to the Branch Council, and if it was consistent with the Council's recommendations for the Executive Committee to undertake such duties.

The PRESIDENT said that the categorical answer to the first question was "Yes," and to the second "No," but that the subject might be further elucidated under Dr. Storrar's motion for a reconsideration of the Standing Orders of the Council with reference to the duties of the committee.

Mr. TURNER, in resuming the debate on the adjourned consideration of the report of the Executive Committee in regard to certain students from India, said there were two questions before the Council—whether the pass examination in Latin was to be insisted on as a necessary preliminary to registration of the student; and whether the licensing bodies were to be allowed to admit to the professional examinations candidates who had not been registered. The Executive Committee had acceded to the applications of the gentlemen from India, who had been registered as students, substituting some other language for Latin. The Council ought not to forget that similar applications had been made on former occasions. Several had been received by the Scottish Branch Council, who declined to register until the students had passed an examination in Latin. Complaints had been made that Indian students had been examined by certain of the Boards without passing in Latin, and special reference had been made to the Society of Apothecaries.

Mr. BRADFORD said that no one was admitted to the first examination at Blackfriars who had not passed a preliminary examination in arts, including Latin. No exception was made to that rule, even in the case of the Indian students.

Mr. TURNER said that as conflicting views appeared to be entertained on the subject, it should be decided by the Council. The Court of Examiners of the Society of Apothecaries had had under consideration the cases of Parsee candidates, and were prepared to institute a special examination in Latin for those who had not already passed in that language. As to the second question to which he had alluded, Sir J. Paget had said that the College of Surgeons of England had reserved to itself the right to take into consideration the cases of students from India and the colonies who had not gone through the examinations required by the Council, and had not been registered. The Scottish Branch Council, however, had decided that in all cases medical students should be registered as such before being admitted to the professional examination, even although their whole course of medical education had been taken out of this country. There was thus a want of uniformity in the matter, and the question was what course ought the Council to adopt. Should it act upon a rigid rule, or make some allowance in the cases under consideration? He thought that a rigid rule should not be established, but that some allowance should be made on good cause being shown. A large number of colonists and Indians came to this country to obtain medical qualifications, and ought the Council to tie up the examining bodies by a rigid rule, and say that no one should be admitted to professional examination unless he had been registered as a student after passing such an examination as the Council had prescribed? He thought not. His own feeling was that discretionary power might be given to the licensing bodies, who might be required to report on all cases in which exceptions had been made, and the reasons for such exceptions.

The PRESIDENT said as Chairman of the Executive Committee he was grateful to Mr. Turner for having put the case so clearly before the Council. It might be a question whether the Executive Committee had been strictly right in the course it had adopted, but their choice lay between that course and summoning the Branch Council from all parts of England to decide upon the cases of seven or eight students, thus bringing to bear upon them a costly and cumbrous machinery.

Dr. PITMAN moved, "That the General Medical Council delegate to the Executive Committee as well as to the Branch Councils the power to make exception to the recommendations on education and examination in cases in which such exception shall seem to them to be reasonable."

Dr. QUAIN, in seconding the motion, said there were cases coming before the Executive Committee of students from the East, to whom Latin would not be of the slightest use, and it would be a great hardship if they were not allowed to commence their studies in England without a knowledge of that language.

Mr. TURNER moved, as an amendment, "That in cases where, for some special reason, candidates for admission to professional examinations by the licensing bodies may not have been able to comply with all the recommendations of the Council as regards the examination in general education and registration thereon, exception may be allowed."

Sir W. GULL said that at present no one could go to the College of Physicians or the College of Surgeons for a diploma without having a certificate of registration from a Branch Council.

Sir JAMES PAGET, in seconding the amendment, said that licentiates from various countries in Europe came to England for diplomas, being already qualified practitioners. Were such persons to be registered as students? He was sure that any of the licensing bodies would exercise the right of dealing with such cases. There were other cases of students who merely came to England to complete their education, and to add to titles acquired elsewhere, having passed an examination fully equivalent to that required in their country, though not, perhaps, including this or that special subject. It would be unfair to exclude all such students, and to require registration before examination. Registration was not compulsory by Act of Parliament, and could not be enforced. The Council should retain sufficient power to check abuses, and do nothing more.

Sir W. GULL thought that all exceptions should be made through the Branch Councils.

Mr. MACNAMARA said that the branch registrar had no power to refuse to register a candidate who produced a licence from the Royal College of Surgeons; he could not compel the candidate to produce evidence of having been registered as a medical student. It was competent, however, for the Council to recommend the bodies not to issue their qualifications unless the candidate had fulfilled the requirements of the Council. He agreed with Sir James Paget that it would be wrong to lay down a hard and fast law. Cases would arise as to what the corporations were best qualified to judge for themselves. The college which he represented had determined in future to send all such cases to the Branch Council.

Mr. SIMON said that the Council had passed no law in reference to the matter, but had only issued a recommendation. He thought that a rider might be added to Mr. Turner's amendment defining the classes of cases to which the exceptions should apply.

Dr. STORRAR said that hitherto the matter had been brought before the Branch Councils, and he was not aware that they had found any difficulty in dealing with it. He looked with suspicion on applications for special exemptions, and if they were too readily received there would be no end to them. It appeared that the Society of Apothecaries had already provided that Cæsar's Commentaries should be presented for examination to candidates coming from India, and that was a sufficient remedy for the difficulty. He objected to providing any special machinery for regulating exemptions. The matter should rest with the Branch Councils.

The amendment was then put and carried, with the addition, after the word "exceptions," of the words (suggested by Mr. Simon), "on principles to be fixed by the General Medical Council."

It was then referred to the Executive Committee, with Mr. Turner, to prepare for the consideration of the Council draft rules defining the classes of cases in which exceptions might be properly allowed.

Mr. SIMON again brought under consideration of the Council the question whether passing the second-class examination of the College of Preceptors, provided the candidate passed in the first division, might be taken to satisfy the requirements of the Council for Preliminary General Education. He moved, "That passing the second-class examination of the College of Preceptors may, on the following conditions, be deemed to satisfy the requirements of the Council for Preliminary Education—that is to say, provided, as regards Section 5 of the examination, that both algebra and Euclid be taken; and provided, as regards Section 6 of the examination, that Latin and also one of the modern languages be taken; and provided that the candidates' pass of the examination be in the first or second division of the pass; and with the understanding that the requirements of the Council in respect of Preliminary Scientific Education are not in any degree diminished by reason of a candidate's having passed the above-described Preliminary *General* Examination."

Mr. TURNER seconded the motion, which was agreed to.

DENTAL BUSINESS.

On the motion of Dr. PITMAN, seconded by Dr. SMITH, Dr. Haldane was appointed a member of the Dental Committee, in the place of the late Dr. Andrew Wood.

A communication was read from the Representative Board of the British Dental Association, thanking the Council for its prompt consideration to the elucidation of certain provisions of the Dentists Act.

Applications were received from a number of registered dentists also holding medical or surgical qualifications, requesting that such qualifications might be added to their descriptions in the Dental Register. Upon these applications,

Dr. STORRAR moved, "That every registered dentist holding any of the qualifications recited in Schedule A of the Medical Act shall be entitled to have such qualification or qualifications recorded on the Dentists' Register, as evidence of the possession of a higher degree of knowledge." The object of the Dentists' Register was to inform the public who were duly qualified and who were not. There could be no doubt that a dentist having a diploma, for instance, of the College of Surgeons was better qualified than one having no such diploma.

Mr. TURNER said he would second the motion if it was limited to the *surgical* qualification recited in Schedule A.

Dr. STORRAR assented to the insertion of the word "surgical" in the resolution.

Dr. QUAIN called Mr. Turner's attention to the resolution previously passed by the Council directing the registrar not to make entries in the column headed "Additional Diplomas," &c.

Mr. TURNER maintained that Dr. Storrar's motion had nothing to do with the "column," but if it had anything to do with it he saw no reason why the Council should not reconsider its decision. Dr. Storrar had made no proposal that there should be a separate column, he had only proposed that the qualifications in question should be recorded in the Register. The Dental Act stated that the Register should contain a list of dentists with the qualifications in respect of which they were registered, and "such particulars and in such a form as the General Council may from time to time direct." The opinion of counsel was that the only additional qualifications which should appear on the Register were such as should express or imply a fitness to practise dentistry. Did not the possession of a surgical qualification imply a superior degree of fitness to practise dental surgery? If it did he maintained that the Council had power to record it on the Register.

Dr. QUAIN said if surgical qualifications were entered, he did not see why physicians should not have the same advantage. He did not think that Dr. Storrar's proposal could be carried out without an amendment of the Act of Parliament.

Mr. SIMON said they were not justified in maintaining as a universal law that a man was a better dentist for being a member of the College of Surgeons. If surgical qualifications were to be entered where were they to stop? If they went beyond actual dental knowledge and requirements they would get into serious difficulty.

Dr. BANKS agreed with Mr. Turner that it would be a hardship to the holders of higher qualifications not to have them entered. Some dentists possessed the same education as medical men, while others were simply tradesmen.

Dr. PITMAN said the question was to determine what was "an additional qualification in dentistry." He maintained that that was the function of the Council, which had powers to "make, and, when made, revoke and vary orders for the registration in and removal from the Dentists' Register of any additional diplomas, memberships, degrees, &c., which appear to the Council to be granted after examination by any of the medical authorities in respect of a higher degree of knowledge." Was not membership of the College of Surgeons a higher qualification as regards dentistry? That was a question for the Council alone to decide.

Dr. SCOTT ORR thought it would be a great hardship to deprive the holders of higher surgical qualifications of the privilege of having them registered; and he thought there would be no objection to their being entered in the first column immediately following the name.

Mr. TEALE agreed with Dr. Pitman, that the Act contemplated that the Council should decide what was a higher qualification in dentistry.

Mr. SPENCE had no hesitation in saying that a man possessing the diploma of one of the medical bodies was certainly better qualified as a dentist than a person not possessing such a qualification; and he saw no reason why the public should be prevented from knowing who were the best men.

Dr. PYLE thought that the entry of the additional qualifications acted as a stimulus to members of the dental profession, and tended to raise their status.

Sir JAMES PAGET said that dental matters often involved questions of constitution, but an ordinary dental qualification implied no power to judge, say, of the liver or other organs of the body, an examination of which might be necessary in order to decide on the proper treatment of the case. It would be difficult to find any case in surgery in which a man who had been educated in regard to one locality alone would be so good a judge as one who had been educated in regard to all. Upon those grounds he could not doubt that if the Council had a right to add such qualifications, it ought to enter them upon the Dentists' Register.

Dr. MCCLINTOCK thought it would be a retrograde movement on the part of the Council to throw any discouragement in the way of men who desired to take higher qualifications.

Dr. HUMPHRY maintained that the "higher degree of knowledge" must be within the meaning of the Act, and that the Council could not go beyond it. It was true that a surgeon might be a better dentist for his surgical qualification, but the same thing might be said with regard to any well educated man. The Council had decided to enter the qualifications and had then taken them off, and he should be sorry to have them put on again without good reason.

Dr. HALDANE would vote for the insertion of the additional qualifications if he thought that the Council had the requisite power, but believing that it would be illegal he felt compelled to vote against Dr. Storrar's motion.

Sir WM. GULL asked why the resolution was limited to "surgical" qualifications, and suggested that a person acquainted with the diseases of women and children would be a better dentist for that qualification.

Dr. STORRAR said he had no objection to introduce medical as well as surgical qualifications.

Dr. PITMAN said in that case he would retract all he had said.

Dr. STORRAR said his desire was to allow all dentists with higher qualifications to place them on the Register, but if he could not succeed in regard to medical qualifications, he would take the opinion of the Council first on the question of surgical qualifications.

Mr. OUVRY, at the request of the Council, called attention to various clauses of the Act, and said it was clear that the Council could not put in the existing column any of the additional diplomas or titles in question. If they were inserted at all they would have to be inserted in the first column after the name. It was for the Council to decide whether the examination which the licentiates had passed was or was not equal to, or higher than, the amount of dental knowledge enabling a person to obtain a dental diploma.

Dr. STORRAR'S motion was then put and carried by a majority of 13 against 5.

Dr. QUAIN said those who held College diplomas, and who practised as dentists, but did not register as dentists, might require the Council to revoke its proceeding if illegal.

It was moved by Dr. PITMAN and seconded by Dr. TURNER, "That the additional surgical diploma, membership, degree, licence, or letter, be entered in the fourth column of the Dentists' Register, and after the original entries."

Dr. SCOTT ORR moved, as an amendment, "That any additional diplomas, memberships, degrees, licences, or letters, be entered in the same column."

The amendment having been seconded, was put and negatived. The original motion was afterwards put and carried.

The Council then adjourned.

FRIDAY, APRIL 29TH.

On the usual motion for the confirmation of the minutes,

Mr. SIMON, referring to the proceedings of the Council yesterday in reference to the Dental Register, asked that the members who objected to those proceedings on the ground of illegality might be permitted to record their protest against them.

Dr. QUAIN asked whether the previous resolution of the Council, at its last sitting, should not have been rescinded before the resolution of yesterday had been passed.

The PRESIDENT said he would answer the question at a future time. Those who protested against the proceedings could, if they desired, vote against the confirmation of the minutes.

Mr. SIMON complained that Mr. Ouvry's opinion had not been placed on the minutes, and moved as an amendment that that opinion against the legality of the proposed motion should be recorded.

Dr. STORRAR and Sir JAMES PAGET objected to Mr. Ouvry's opinion being entered on the minutes. They had no objection, they said, to the statement of the fact that Mr. Ouvry had given his opinion.

The question was rather warmly discussed for some time, and ultimately Mr. Simon's proposal was negatived, the PRESIDENT remarking that perhaps Mr. Simon's object would be attained by the insertion of his amendment on the minutes. It was then resolved that a record should be made of the fact that Mr. Ouvry was asked to give, and gave, his opinion on the interpretation of the Act.

The following is an abstract of the report presented by the Finance Committee:—

"The Finance Committee reports that the income of the General and Branch Councils for the year 1880 (ending January 1st, 1881) has been £6871 19*s.*, an amount which exceeds the income of the year 1879 by £702 5*s.* The expenditure during the year 1880 has been £5303 18*s.*, which is less than the expenditure of 1879 by £116 9*s.* 9*d.* The committee has the satisfaction of reporting to the Council that the income during the year 1880 has exceeded the expenditure by the sum of £1568 1*s.* The items of expenditure in which there is an increase in the year 1880 over that of 1879 are:—(1) On the Pharmacopœia, the expenditure for which amounts to £483 5*s.*, due to a reprint of the work being required during the year. This outlay is in course of reimbursement. (2) The other items on which a noticeable increase of expenditure has taken place are miscellaneous printing, amounting to £98 10*s.* 1*d.*, and on the Medical Registers, £60 3*s.* 4*d.* The increase in the expenditure of 1880 over 1879 in regard to certain items is £732 2*s.* 5*d.* The principal items of diminished expenditure of the year 1880, as compared with 1879, are in the fees paid to the Council, amounting to £533 13*s.* 6*d.*; in salaries and retiring allowances (the retiring allowance to one of the late clerks having lapsed by his death), amounting to £94 5*s.* 5*d.*; and some smaller sums, amounting altogether to £779 2*s.* 4*d.* This will show, on the whole, a decrease of £46 19*s.* 11*d.* The average income of the General and Branch Councils during the last seven years exceeds the annual average expenditure by the sum of £62, whilst the excess of income during the years 1879 and 1880 is respectively £961 10*s.* and £1568 1*s.*

"DENTAL FINANCE.—On January 1st, 1881, there remained to the account of the Dental Fund a sum of £9000 of New 3 per Cent. stock, and in the bank £824 8*s.* 11*d.*, making a total of £9824 8*s.* 11*d.*; but it must also be noticed that while the total income of this fund during 1881, from all sources, amounted only to £616 7*s.* 3*d.*, the expenditure amounted to £1808 10*s.* 7*d.*, leaving a deficiency of £1192 3*s.* 4*d.* to be met out of invested capital.

"By request of the committee, the registrar has prepared the following roughly approximate estimate of the probable future annual income and expenditure of the Dental Registration:—

ESTIMATED INCOME.	£	*s.*	*d.*	ESTIMATED EXPENDITURE.	£	*s.*	*d.*
Dividends	274	0	0	Proportion of General Council's Fees	510	0	0
Fees (at present rate)	250	0	0	Fees for Executive and Dental Committees	117	0	0
Total Income	524	0	0	Proportion of General Expenses	500	0	0
Deficiency	883	0	0	Printing	150	0	0
				Law Expenses	50	0	0
				Miscellaneous	80	0	0
	£1407	0	0		£1407	0	0

"This table shows a probable future excess of expenditure over income of about £880, which will have to be met by drafts on the invested capital."

Dr. QUAIN moved and Dr. SMITH seconded the adoption of the report.

Mr. TURNER remarked that if the calculated annual deficiency in the dental account went on for ten years the Dental Fund would be bankrupt.

Dr. QUAIN said they anticipated a considerable increase in the fees in future.

Mr. TURNER said it was a question whether the dentists had not been somewhat over-weighted in the proportion they were called upon to pay towards the expenses of the Council.

Dr. QUAIN said that the registrar was very scrupulous in his division of the expenses so as to make it as accurate as possible.

The PRESIDENT was very anxious that something should be done to diminish the expenses.

A report was received from the General Branch Council recommending an alteration in Section 5 of Chapter 16 of the Standing Orders, with reference to the appointment of trustees of the funds of the Branch Councils.

Dr. QUAIN, in moving the adoption of the recommendation, explained that at present, when a trustee ceased to be a member of the Council, it was necessary to appoint another who was a member; and as that involved considerable expense it was proposed that a trustee once chosen should continue in the office whether a member of the Council or not.

The motion was agreed to.

Mr. MACNAMARA moved, "That it is desirable to hold a stated meeting of the General Medical Council once in each year." He did not wish to interfere with the prerogative of the President to convene at any time a meeting of the Council, but he thought that a stated meeting once a year would be a great advantage to the members. The President would still have the power of convening special meetings whenever he thought it desirable.

Dr. LEET seconded the motion.

Dr. BANKS said he had been requested by Dr. Haughton to express his great regret that it was quite impossible for him to attend. It was also extremely inconvenient for himself (Dr. Banks), but he was quite sure that the President had exercised a wise discretion.

Dr. STORRAR said that there had been no greater difficulty experienced by the Presidents of the Council than that of fixing its meetings. At the same time he thought the duty should still rest with the President, who would do his best to meet the general convenience of the members and the exigencies of the business of the Council.

Dr. SMITH concurred in the views of Dr. Storrar. A special meeting of the Council, he said, could be summoned at any time in cases of emergency.

The PRESIDENT, in putting the motion, said that with reference to one meeting of the Council he had written seventy or one hundred letters before fixing the time, and that on another occasion he had consulted the Government as to the time when the second reading of a Medical Bill would come on. He hoped that the time would come when the Council would be able to hold its meetings at stated periods, but he hardly thought that that happy time had yet arrived. With regard to the present meeting, as soon as he learned that Dr. Haughton could not attend he considered whether it would not be his duty to postpone it, although the time had been settled for some days, by writing personally to every member on the subject; having, however, carefully considered the matter, he decided that it would not be in the public interest to adopt that course. The duty of arranging for the meeting, he need not say, was a very anxious one.

Mr. MACNAMARA said that after the kind words of the President he would withdraw the motion.

Mr. MACNAMARA moved, "That it be recommended to the several licensing bodies to institute examinations at the end of each year of professional study, which the student should pass before being permitted to enter on the subsequent year's course of study." The motion, he said, was in accordance with the expressed opinions and recommendations of the Council, which had almost unanimously decided that the examinations should be broken up into departments. Anyone who had had experience in medical education would know that in the first year of study pupils were ardent and diligent, that they often relaxed in the second, were still more indifferent in the third, and redoubled their efforts in the fourth to make up for lost time. It was, therefore, desirable that at the end of each year the pupils should be tested in the studies they had gone through in the year. He did not propose any formal method, but would leave it to the discretion of the several authorities. In many cases parents and guardians sent their sons to receive a medical education, and paid large sums for that purpose, which in the end were found to have been wasted owing to the failure of the students. If the failure were discovered at the end of the first year but little expense would be incurred, and the student's efforts could be directed elsewhere.

Dr. MCCLINTOCK seconded the motion.

Mr. TEALE objected to the motion as being a mere reaffirmation of an existing recommendation of the Council.

Mr. SIMON said he could not quite adopt Mr. Macnamara's motion, but he was of opinion that there should be a division in the professional education, and that time should not be allowed to count in the more advanced studies until an examination had been passed in the earlier part of the curriculum.

Mr. MACNAMARA having replied, the motion was put and negatived, only two members voting in its favour.

The Council then proceeded to the consideration, in private, of a motion by Mr. TURNER, "That it be remitted to the consideration of the Executive Committee to reconsider and amend the Standing Orders bearing on the mode of procedure to be followed in cases where inquiry is to be made into the case of registered medical practitioners charged with being guilty of infamous conduct in any professional respect."

The motion was adopted.

On the readmission of strangers, the Council took into consideration the answers from the medical licensing bodies to its resolutions in regard to the institution of a preliminary scientific examination, together with the report of the committee appointed to communicate with the licensing bodies on the subject. After setting out the resolutions of the Council and the questions forwarded to the medical authorities by the committee, the report proceeded:—"Answers have been sent in by sixteen of the licensing bodies. The University of Dublin does not approve of the resolutions, 'their principle being contrary to that of the present system of Trinity College, which they consider superior'; the University of London enters into no detail, but merely refers to its own regulations as published in the Calendar of the University. The other fifteen bodies have answered more or less in detail. The following digest expresses generally the opinion entertained by these bodies with regard to the questions submitted to them:—1. *Subjects of examination.* On this point the universities adhere to their own practice, and express no opinion as to what should be required as a minimum qualification. There is more diversity of opinion on the part of the corporations. The College of Physicians of Edinburgh considers the present preliminary examination sufficiently extensive, but would make natural philosophy a compulsory subject; the College of Physicians in Ireland recommends an examination in the elements of mechanics, hydrostatics, physics, and chemistry; the College of Surgeons of England would encourage study in one or more branches of natural science; the College of Surgeons in Edinburgh recommends mathematics, as at present, elementary physics, and chemistry; the College of Surgeons in Ireland recommends physics, elements of chemistry and botany; the Glasgow Faculty, physics, chemistry, and 'perhaps an elementary knowledge of general biology'; the Apothecaries' Hall in Ireland recommends elementary mechanics, chemical physics, and the elements of zoology and botany.—2. *Should proficiency as ascertained by examination be sufficient? or should proof of special instruction be required?* The universities for the most part require proof of systematic instruction. The corporations are generally in favour of the examination test alone. The Apothecaries' Society of London is of opinion that evidence of special instruction should be required. The Glasgow Faculty would recommend, but not require it.—3. *Time of passing examination.* The University of St. Andrews, the College of Physicians of Edinburgh, the Colleges of Physicians and Surgeons of Edinburgh, the Glasgow Faculty, and the Apothecaries' Halls in England and Ireland, recommend that the examination be passed before the commencement of the medical curriculum; the Colleges of Physicians and Surgeons in Ireland, during or at the end of the first year of the medical curriculum; the Universities of Edinburgh and Glasgow, not earlier than the end of the first year of the medical curriculum; the University of Cambridge, as soon as the student pleases, provided not less than three full years intervene between it and obtaining a degree or diploma.—4. *Should passing in a subject at the general preliminary exempt from re-examination in the same subject at the scientific preliminary examination?* On this point the universities would adhere to their present practice, which in most instances admits no exception, but the University of Edinburgh suggests:—'If a candidate has already passed an examination in chemistry, botany, or geology, such as that required for a degree in science, this should *pro tanto* exempt him from further examination.' The College of Physicians in Ireland would require the full scientific preliminary to be passed; the three Colleges of Surgeons would exempt (the College of Surgeons of England partially); the Glasgow Faculty, provided there are to be two examinations, would make the first literary, the second scientific; the Apothecaries' Society of London would require the examination in natural science subject to be compulsory either at the preliminary general examination or at a second or preliminary scientific examination.—5. *Modifications in the medical curriculum consequent on establishment of a preliminary scientific examination.* The Universities of Edinburgh and Glasgow and the Colleges of Physicians and Surgeons in Ireland would make no modification; the College of Surgeons of Edinburgh and the Glasgow Faculty would exclude chemistry, if passed at the preliminary examination, from the medical curriculum; the Universities of Cambridge and St. Andrews and other bodies cannot reply without knowing what is to be the nature of the preliminary scientific examination. From a consideration of the answers, of which an abstract has been given, it will be seen that there is a considerable difference between the views of the universities, on the one hand, and of the corporations on the other, the former adhering to their present standard, the latter keeping in view the danger of raising the standard too high. It may be expected that there will be a decided difference in the requirements for a degree and a mere licence to practise, and that the difference would consist not merely in professional education and examination, but also in the standard of literary and scientific acquirements. Thus, while it is right that candidates for a degree should be required to possess a good general knowledge of biology, it does not seem desirable that knowledge in so wide a range should be required from every medical student. The committee are of opinion that in the case of non-university students, instead of a special preliminary scientific examination, it would be better to carry out a recommendation (31) of the Medical Council, respecting a first examination, to be passed at any time before the end of the first year of medical study, and to include elementary mechanics (if not previously passed), chemistry and chemical physics, and elementary human anatomy or elementary biology. There is reason to believe that the first year, at least, of medical study is too often wasted, in consequence of the first examination, which in many instances does not take place till the end of the second year, being looked upon as something in the remote future; whereas the institution of an examination to be passed at an earlier period would necessarily give a stimulus to early exertion. In conclusion, your committee would beg to recommend:—Firstly, that the natural science subjects remain, as at present, optional subjects at the preliminary examination in general education; forty-five months to elapse between that examination and the final examination, as at present. Secondly, that the attention of those licensing bodies which have not complied with Recommendation 31 of the Medical Council be directed to that recommendation; and that it be further recommended that the subjects of this first professional examination be:—1. Elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics (unless an examination in that subject shall have been passed at the preliminary examination). 2. Chemistry and chemical physics (meaning thereby heat, light, and electricity). 3. One or more subjects of elementary biology, which may be elements of human anatomy, or of human anatomy and physiology, or of botany, or of zoology and comparative anatomy. The committee are of opinion that it is desirable that evidence of attendance on lectures and practical instruction in chemistry should be required; but they do not think that this is necessary in the case of elementary mechanics. They would observe, however, that the Council have not hitherto issued recommendations relating to requirements of attendance on lectures."

Dr. HALDANE, in moving the adoption of the first recommendation in the report, after explaining the reasons for the delay in submitting it to the Council, said that when he entered upon the inquiry he was not very hopeful that it would lead to any satisfactory result, because he regarded the requirements of general preliminary education as being already too extensive. Though not coming strictly within the range of the report, he had a few figures which he desired to lay before the Council with reference to the results of preliminary examinations which had lately taken place in Scotland before the University of Edinburgh, where there were 412 candidates, and the Colleges of Physicians and Surgeons of Edinburgh, where there were 109 candidates. Of the candidates before the university 24 per cent. failed in English, and before the Colleges of Physicians and Surgeons 37 per cent. In Latin the failures were 27 per cent. and 62 per cent.—the latter proportion being exceptionally large. In Greek the failures at the university were 27 per cent., but there were no failures at the colleges—the subject being an optional one, and only four candidates taking it up, all of whom passed. In French 42 per cent. failed at the university and 54 per cent. at the colleges. In German 8 per cent. before the university and 20 per cent. at the colleges. In arithmetic the failures were 17 per cent. and 33 per cent.; in mathematics 24 per cent. and 51 per cent.; in natural philosophy 25 per cent. and 30 per cent. With those figures before them it seemed hopeless to endeavour to raise the standard of preliminary education. It was very rare that a student passed in all the subjects at once in the Colleges of Physicians and Surgeons. Of the 109 candidates only one passed the entire preliminary examination, it being the custom of the candidates to come up twice or three times, and no doubt it was the same thing in the university. That showed the melancholy state of secondary education throughout the country. It was not so much the fault of the young men, who appeared to be fairly intelligent, as it was the fault of the system of education. He thought that the plan proposed in the report would be found useful without adding anything to the present requirements of candidates. The committee were of opinion that there should be a decided difference between the requirements for a degree and a mere licence to practise, but he thought that that difference should be mainly, if not entirely, in the scientific subjects, not in the practical and professional. They had a right to look for more highly educated men amongst university graduates, but those who were licensed by the corporations ought to be thoroughly qualified for the practice of their profession. The committee were satisfied with the requirements of the universities as to preliminary and scientific education, and did not propose to interfere with them. They had carefully considered the recommendations of the Council decided upon last year, that a preliminary scientific examination should be instituted, and also the best method of carrying it out, and the conclusion to which they came was that it should not be called a primary preliminary scientific examination, but a first professional examination to be passed during the first year of medical study. According to the scheme given in the report (and quoted above), therefore, the first preliminary examination would remain as at present. He agreed with Mr. Macnamara, that it was desirable that the examination of medical students on professional subjects should be instituted at an early period. The committee were of opinion that attendance on lectures should not be enforced in the case of physics, but that in the case of anatomy and chemistry the evidence of such attendance should be required.

Mr. TEALE said that if the subjects to which reference had been made were pressed, the result would be an additional examination, because it was tolerably clear that a small proportion of students would be able to take them up in their general preliminary examination. The more examinations were multiplied the more they were likely to impair medical education in certain directions. If the proposed examination were to be an additional one, taking the student to the great centres a third time instead of twice only, great additional expense would be entailed, and if the examination were very strict the students might be thrown back in their studies.

Dr. PETTIGREW said he had some difficulty in receiving the report in its totality. It appeared to him that an undue prominence had been given to the elementary mechanics of solids and fluids, and that an insufficient prominence had been assigned to other subjects equally important, such as physiology, botany, and zoology.

Dr. PITMAN moved, as an amendment, that the report should be referred back to the committee, with the request that, after they had received and considered the answers from all the medical authorities, the report should be revised and sent to each member of the Council preparatory to its consideration at the next session. It was impossible, he said, to do justice to the subject at present, or to arrive at a practical result.

The further consideration of the subject was adjourned, and the Council proceeded to transact the remaining dental business on the programme. Three dentists whose cases had been referred to the Council by the Dental Committee were decided to have been duly registered, and the cases of two others were referred to the Dental Committee for further inquiry.

The Council then adjourned.

SATURDAY, APRIL 30TH.

At the meeting of the Council to-day,

Dr. QUAIN, pursuant to notice, asked the following question. A resolution was adopted by the General Council on March 26th, 1879, having reference to an important feature in the formation of the Dentists' Register. A resolution entirely altering the resolution referred to was adopted by the Council on April 28th, 1881. The question is: Is it or is it not correct, as a matter of order, "that an original resolution should be rescinded before a new resolution is proposed?"

The PRESIDENT said that generally it would, no doubt, be more regular to rescind an original resolution before a new one was passed; and in the case in question it might have been better if the second resolution had been framed, setting forth that the first was rescinded, but inasmuch as the latter resolution did in fact rescind the former, it hardly appeared that that course was necessary. The President further said that the two other questions had been asked him by the registrar with reference to the carrying out of the Council's instructions as to the Dentists' Register. (1) Is a diploma not registered in the Medical Register registrable in the Dentists' Register? (2) What qualifications are registrable as surgical qualifications?—e. g., is the licence of the College of Physicians of London to be so registered? Perhaps the Council would allow him to depart from the usual course of giving a categorical answer to those questions.

Dr. PITMAN said they could scarcely expect the members of the Council to answer questions involving legal interpretations, and it would be undesirable to leave the matter with the President without the assistance of the solicitor. The proper course would be to take the solicitor's advice.

Dr. QUAIN thought the Council might be placed in a very awkward position by the course that had been adopted. It would have been better if the Council had said that the qualifications already registered in the Medical Register might be placed on the Dentists' Register.

Dr. STORRAR thought they had already had too much law, and that the better course was to rely upon common sense. The College of Physicians had a charter of Henry VIII. distinctly declaring that the science of medicine included surgery. Its licence was conferred after an examination in medicine and surgery, and it was therefore a surgical qualification. ("No, no.")

Dr. PITMAN said it was recognised by the Local Government Board as a surgical qualification.

Mr. TURNER said that in that case a great injustice was being done to the Scotch universities, because the degree of Bachelor of Medicine in those universities, though granted after an examination in medicine and surgery, was not accepted by the Local Government Board as a surgical qualification; and the candidates were therefore obliged to have another diploma, that of Master in Surgery.

Sir WM. GULL said that the Council had been doing a most stupid thing in deciding that surgical qualifications alone should be entered. A knowledge of the diseases of women and children might save a great many teeth. He could see no reason why, if a dentist was an M.D. of the University of London or a licentiate of the College of Physicians, he should not be allowed to enter the qualification on the Register.

Dr. STORRAR: Will you move that medical qualifications be also entered?

Sir WM. GULL: Yes; and I think midwifery qualifications should be entered too.

Dr. SCOTT ORR said he should be glad to second Sir W. Gull's proposal.

Dr. STORRAR said the question was a purely medical one, and the opinion of the Council was more satisfactory than that of the lawyers. He objected to the motion which had been already passed being sent back to be strangled.

Mr. TURNER said he did not think that the proposal to take legal advice upon the matter was at all antagonistic to the resolution already passed by the Council. The sole object was to carry out that resolution strictly.

Dr. QUAIN maintained that the matter had been finally settled, and could not be reopened.

Sir WM. GULL said that the resolution already passed was only an instalment, the understanding being that something more was to follow.

Mr. SIMON hoped that, pending the further consideration of the matter, the Council should refrain from taking action in pursuance of the resolution already passed.

The PRESIDENT pointed out that other questions might also arise as to whether similar difficulties might present themselves. Of course, if the Council came to no decision in the matter the President and the registrar would have to exercise their judgment in the best way they could.

Sir JAMES PAGET said that if the question were referred to the President and the registrar they would of course be at liberty to obtain legal assistance before arriving at at decision.

Dr. HUMPHRY said he should be sorry to complicate the matter, but he wished to point out that "Surgical qualifications in Schedule A of the Medical Act" had no existence. No such things were mentioned in the Act.

Dr. Pitman's motion was then put and carried, thirteen members voting in its favour.

The adjourned debate on Dr. Haldane's motion with reference to the recommendation of the Executive Committee as to preliminary examination was resumed.

Dr. HUMPHRY said he regretted that there was a difficulty in the way of proceeding with Dr. Haldane's motion. It was, he considered, almost a dereliction of duty not to enter at once into the consideration of the question, but he felt that the discussion as to the desirability of entering upon it would of itself occupy the entire sitting of the Council, and (judging from the expressions of opinion he had heard) to no purpose. He believed, therefore, that Dr. Haldane was prepared to state that the consideration of the report of the Executive Committee would not be proceeded with.

Dr. HALDANE said he entirely approved of the course which had been recommended, and he accordingly agreed to the amendment, that the report be referred back to the committee and again brought forward at the next session.

Mr. MACNAMARA said he objected to Dr. Haldane's motion being withdrawn. The question had been discussed for many years, and it was a most important one, lying at the foundation of the profession, and he believed that by remitting the matter to the committee when the object they desired was almost within their grasp, they would be damaging the reputation of the Council, and putting the students throughout the country in a state of ferment.

Sir WM. GULL said that some of the answers from the licensing bodies were very vague, and that further inquiries were necessary before a final decision could be arrived at.

Mr. SIMON suggested that a middle course might be adopted. The Council might be unable to enter into minute details, but it might do something to help forward the principle which it was desired to promote. Instead of shelving the matter the Council might adopt the course which Dr. Fergus and himself had proposed on a previous occasion—that of suggesting to the licensing authorities to consider whether they could separately or conjointly take steps to promote the establishment of a preliminary scientific examination, and to require that all candidates for their licences after passing a preliminary examination in general education, should, either before commencing the purely medical curriculum or before the end of the first year thereof, pass such a preliminary examination as was proposed.

Dr. HALDANE said he quite agreed with Mr. Simon's proposal, and was prepared to withdraw his motion in favour of it.

After some further conversation it was agreed, "That it be recommended to the several licensing authorities under the Medical Act, to consider whether they can, separately or conjointly, take steps to promote the establishment of a preliminary scientific examination, and to require of all candidates for their respective licences that, after passing the preliminary examination in general education, and either before commencing the purely medical curriculum, or, at latest, before the end of the first year thereof, they shall pass such a preliminary scientific examination as is proposed."

Sir JAMES PAGET proposed, "That the whole subject be referred to the same committee, with a request that, after they have received and considered the answers from all the medical authorities, they report thereon, and that their report be sent to each member of the General Council, preparatory to its consideration at the next session of the Council."

The motion was seconded by Dr. BANKS, and agreed to.

Dr. STORRAR moved, "That the Standing Orders as regards the duties of the Executive Committee be reconsidered by the Council." In doing so, he said he had already during the present session called attention to what he considered rather an extreme course taken by the Executive Committee in superseding the action of the General Council. What they had to do was to consider and report on definite questions submitted to them, though he did not go the length of saying that there may not be extreme cases of urgency when it might be desirable to take further action. There was a considerable sense of soreness among the dentists in regard to the manner in which the dentist business had been conducted by the committee. The educated leaders of the dentists had been seriously desirous of improving their profession, and had been glad to hand the matter over to the Medical Council, who were therefore in some degree trustees to the dentists. They ought, then, to transact their business in such a way as to give the dentists the opportunity of giving advice on questions which particularly concerned them. What took place last year? Two opinions of counsel were obtained, but the publication of those opinions was objected to on the ground that there was a conflict of opinion on some plea. When the Executive Committee met after the Council had risen they set to work to take their own course as to the manner in which the several applicants for registration connected with pharmacy should be registered. He had looked in vain through the minutes of the Executive Committee to see in what way the question was laid before Sir Farrar Herschel and Mr. Mackenzie. In common with other members of the Council he received a copy of the case, but as it was marked "Strictly confidential, for the use of the Council only," he was bound in honour not to show it to Mr. Tomes and other dentists, who were of opinion that Sir Farrar Herschel and Mr. Muir Mackenzie's opinion was unsound. It was even a question whether they would not seek a judicial decision from the law courts. In matters of this kind the proper course was to have the case fairly argued on both sides. He thought it might be possible to alter the action of the Executive Committee by altering the Standing Orders under which they were governed.

Dr. PYLE seconded the motion. Two months ago he wished to bring something before the Branch Council, but he felt himself perfectly disfranchised, as no meetings were being held.

The motion was subsequently withdrawn.

On the motion of Dr. HUMPHRY, seconded by Dr. PITMAN, the following report was received, ordered to be entered on the minutes, and adopted.

REPORT BY THE COMMITTEE ON SWISS MEDICAL EXAMINATIONS.

"The committee appointed on April 26th, 1881, to consider the latest regulations for the conduct of the Swiss Medical Examinations, which have been transmitted to the Medical Council by the direction of the Lord President of the Privy Council, reports as follows:—The regulations appear to have been framed with much care, and to provide that the candidates shall be well tested in the various subjects of professional study. The examinations are under the control of a committee of direction, consisting of five members, appointed by the Federal Council, selected from the five localities in which examinations are held, and of two assessors (Section 3). The examination for a diploma is in two parts—a first part, or 'examen propédeutique,' in physics, chemistry, botany, zoology, and comparative anatomy, anatomy and histology, and physiology; a second part, or 'examen professional,' in pathological anatomy, pathology and therapeutics, surgery and surgical anatomy, obstetrics, ophthalmology, and legal and sanitary medicine. The examinations are practical (including examination in writing) and oral. When foreigners desire to submit themselves to the Federal examinations each case must be submitted to, and approved by, the committee of direction. Foreigners who, after due examination, have obtained a foreign diploma, giving full privilege to practise in their respective countries, can only obtain the Federal diploma after having gone through the whole professional examination, unless an international treaty of reciprocity recognises the validity of the foreign diplomas. It is, however, in the power of the committee of direction to admit foreigners of high scientific reputation, or who have been in practice ten years, to an 'examen sommaire,' which will be an oral examination in pathological anatomy, special pathology, and therapeutics, surgery, and obstetrics, or to exempt such foreigners from examination altogether. The committee views with satisfaction the opportunities offered by these provisions which are made, seeing that they are made under the circumstances of there not being any international treaty of reciprocity for giving validity to foreign diplomas."

The report of the Business Committee was also adopted.

"The Business Committee begs leave to report that, having considered the motion referred to them—viz., 'That Chapters I. and IV. of the Standing Orders be referred to the Business Committee to report whether any, and if so what, alterations or additions they would recommend in those sections of the Standing Orders,' recommends that in Chapter IV. of the Standing Orders the following clauses be added after Clause 7:—(1) The Business Committee shall continue in office for a period of one year from the date of its appointment, or, if the Council be not sitting at the time when the year expires, until the first day of the next meeting of the Council. (2) Should there occur, during the recess, any vacancy in the Business Committee, the Executive Committee shall be empowered to fill up such vacancy. (3) In Chapter I., Clause 3, after the words 'The General Registrar shall,' add, 'with the Chairman of the Business Committee.' (4) After Clause 3, add the following Clause: Any notice of motion to be submitted to the General Council on the first day of the session must be sent to the registrar at least six clear days before the beginning of the session."

Dr. PITMAN moved, and Sir JAMES PAGET seconded, "That the additions and alterations suggested in the report by the Business Committee be adopted."

This was agreed to, as was also the reception of the following report, moved by Dr. Pitman, seconded by Dr. Banks.

REPORT BY THE REGISTRATION REGULATIONS COMMITTEE.

The committee appointed April 28th, 1881, to prepare for the consideration of the Council draft rules defining the classes of cases in which exceptions may be allowed to the recommendations of the Council as regards the examination in general education and registration, reports as follows:—"That exceptions may be made in the case of a student from an Indian, colonial, or foreign university or college who shall have passed the matriculation or other equivalent examination of his university or college, provided such examination fairly represents a standard of general education equivalent to that required in this country. Before any such student can be registered, sanction must be given in Scotland and Ireland by the respective Branch Councils of those countries, and in England, either by the Branch Council for England, or by the Executive Committee, as may be most convenient. In case a graduate in medicine of an Indian, or colonial, or foreign university, or a student who, having completed the full time required by the Medical Council, and having given satisfactory evidence of general education, shall have spent the whole or three-fourths of that period at an Indian, colonial, or foreign university, is admitted to examination by any of the licensing bodies, the licensing body is requested to report the particulars of each such case to the General Medical Council."

The following resolutions on the report were agreed to:—"That after Recommendation 8 of the Council's Recommendations on Education and Examination, a proviso be inserted to the effect that, in the opinion of the Council, exception to Recommendations 7 and 8 may properly be made in the case of a student from any Indian, colonial, or foreign university or college, who shall have passed the matriculation or other equivalent examination of his university or college, provided such examination fairly represents a standard of general education equivalent to that required in this country. That, after Recommendation 20 of the Council's Recommendations on Education and Examination, a proviso be inserted to the effect that, in the opinion of the Council, exception to Recommendation 20 may properly be allowed in the case of any graduate in medicine of an Indian, or colonial, or foreign university, or of any student who, having completed the full time required by the Medical Council, and having given satisfactory evidence of general education, shall have spent the whole or three-fourths of that period at an Indian, colonial, or foreign university. That in Recommendation 15 of the Council's Recommendations on Education and Examination, line first, after the words 'Branch Councils,' be inserted the words 'and in England the Executive Committee, if its meeting be more convenient and the case be urgent.' That the several licensing bodies be requested to communicate to the Council annually, in the month of January, a statement of the action taken by them respectively during the last preceding calendar year, in regard of exceptional cases under Recommendation 20 of the Council's Recommendations on Education and Examination."

Other resolutions were also passed, vesting the usual "powers and duties" in the Executive Committee till the next meeting of the Council; and tendering the thanks of the Council to the President, to Dr. Pitman (Chairman of the Business Committee), to the Treasurers, Dr. Quain and Dr. Pitman, and to the Registrar.

The Session then terminated.

ANNUAL REPORT
ON THE
CONTAGIOUS DISEASES ACTS FOR 1880.

THIS report will attract the more attention for those interested in the Contagious Diseases Acts, as the Select Committee is now engaged in receiving evidence as to their being continued or repealed. We have, therefore, thought it advisable to make an analysis of its contents, and to lay its chief conclusions before our readers.

The Assistant Commissioner of the Metropolitan Police reports that the members of the police employed under the Acts have discharged their duties to his entire satisfaction, and that not a single case of excess or violation of duty has been brought under his notice, whilst the common women in the several places subject to the Acts have attended for medical examination with great regularity. 1624 have been registered for the first time during the year, of whom many have come from unprotected districts, and 367 who had been removed from the register were re-registered, making 1991, which, with 1795 remaining from last year, make a complete total of 3786 women under the surveillance of the Acts. Of these 1879 remained on the register at the end of the year. This number is an increase of 84 on the year preceding, and is the highest total since 1875, but is still nearly 800 less than in 1870, from which period until 1877 there was a steady decrease; the numbers since then have fluctuated a little from year to year, but at present are 97 more than in 1876, being 55 in excess of any of the past five years. The removals from the register are of great interest, and are thus classified: 927 left the district, 67 married, 262 entered homes, 629 returned to their friends, and 22 died. The mortality is extremely small, for during the past five years it has remained steadily at less than 6 per 1000. The amount of obstruction to the Acts on the part of the women themselves was so small that in only eleven cases was it necessary to apply to the magistrate for an order. Imported disease from unprotected places figures largely in the returns, inasmuch as out of 612 prostitutes who were known to have arrived from places outside the Acts, 404 (66 per cent.) were found on their first medical examination to be diseased, and a large proportion of them seriously. These imported cases form nearly a fourth of the total number of women (1849) admitted to the various Lock hospitals during the year, and they are especially fruitful in spreading venereal diseases, as there is no possibility of reaching them until they are discovered by the police and brought up for medical examination. With regard to the work of reclamation, the beneficent value of which can scarcely be estimated, we find 93 young girls under eighteen, 86 women under thirty, and 7 above that age have been rescued from bad company and immoral places. Of these 13 were under fifteen years of age. Besides these 174 had commenced an immoral life, but abandoned it on being cautioned, and are therefore not registered. Of these 4 were under fifteen, and 45 under eighteen years of age. The difference between the amount of disease in those who were examined for the first time and those who were on the register from the previous year is very startling, and deserves great attention from the advocates of repeal, for in the former case 40·95 per cent. were found to be diseased, whilst in the latter it amounted to only about 8. The number of the women in both classes was so nearly equal as to prevent the statistics being vitiated by any error of average numbers.

In conclusion, we may refer to a few points which have attracted our notice in making this analysis. In Portsmouth there are 30 prostitutes under eighteen years of age, including 2 under fifteen, 4 under sixteen, and 9 under seventeen. In no other district is there one under sixteen. In Chatham there are 2 under seventeen, and in Aldershot and Colchester 1, whilst in other districts they all exceed this age. These facts should surely command the attention of the various reformatory agencies in those towns. Again, in Devonport, out of 287 newly registered women, 133, or nearly one-half, were found to be diseased on being medically examined; and Dover (50 per cent.), Colchester (52), Aldershot (62), and Maidstone (63) even exceeded this proportion. In the case of previously registered women the greatest proportion of venereal cases existed at Deal (30 per cent), Winchester (22), and Aldershot (13); whilst Sheerness, Windsor, and Gravesend were, as far as such women were concerned, entirely free from venereal diseases at the time of the first medical examination.

THE ROYAL COMMISSION ON THE MEDICAL ACTS.

(From *The London Gazette*, May 3rd, 1881.)

WHITEHALL, MAY 2ND, 1881.

THE Queen has been pleased to issue a Commission under Her Royal Sign Manual in words and to the effect following:—

VICTORIA, R.

VICTORIA, by the Grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, to our right trusty and right well-beloved cousin Robert Adam Philips Haldane, Earl of Camperdown; the Right Reverend Father in God William Connor, Bishop of Peterborough; our right trusty and well-beloved Councillor William Henry Ford Cogan; our right trusty and well-beloved Councillor Sir George Jessel, Knight, Master or Keeper of the Rolls and Records in Chancery; our right trusty and well-beloved Councillor George Sclater-Booth; our trusty and well-beloved Sir William Jenner, Baronet, Knight Commander of our Most Honourable Order of the Bath; our trusty and well-beloved John Simon, Esquire, Companion of our Most Honourable Order of the Bath; our trusty and well-beloved Thomas Henry Huxley, Esquire, Doctor of Laws; our trusty and well-beloved Robert McDonnell, Esquire, Doctor of Medicine; our trusty and well-beloved William Turner, Esquire, Bachelor of Medicine; and our trusty and well-beloved James Bryce, Esquire, greeting!

Whereas it is of importance to all classes of our subjects that the conditions under which persons are permitted to represent themselves as qualified medical practitioners should be such as to afford the best attainable security for their skill and knowledge in medicine and surgery.

And whereas powers in relation to the education and examination for a grant of medical degrees, diplomas, or licences, to medical practitioners are by various statutes and charters vested in certain universities, medical colleges, and other bodies in the United Kingdom.

And whereas under "The Medical Act, 1858," and the Acts amending the same, the General Council of Medical Education and Registration was constituted, and vested with a superintendence over the exercise of the said powers, and also with entering in a register of medical practitioners, and removing therefrom the holders of certain medical qualifications obtained in the United Kingdom, exclusive of those obtained in our colonies or in foreign States.

And whereas by the last-mentioned Acts certain exclusive privileges were conferred on the persons so registered, and persons not so registered were placed under certain restrictions, disabilities, and penalties.

And whereas divers representations have been made in Parliament, and otherwise, and both from our subjects in the United Kingdom, and from the Governments of our possessions out of the United Kingdom, in relation to the unsatisfactory position of the above matters.

And whereas we have thought it expedient that, with a view to legislation, further inquiries should be made into the above matters, and that a commission should forthwith issue to inquire into the grant of medical degrees, memberships, fellowships, licences, and other diplomas by universities, colleges, and bodies in the United Kingdom, and the courses of education and examination, payments, and other conditions required as a preliminary to such grant, and into the skill and knowledge which such degrees, memberships, fellowships, licences, or diplomas represent; and further to inquire into the conditions and manner under or in which medical practitioners are entered in and are struck off the register of medical practitioners, and the privileges of registered and the disabilities of unregistered practitioners, and the position of medical practitioners so registered in our possessions out of the United Kingdom, and the position in the United Kingdom of medical practitioners educated in our possessions out of the United Kingdom, or in a foreign State.

And further to inquire into the constitution, functions, powers, and procedure of the General Council of Medical Education and Registration, and their relation to the above-mentioned universities, colleges, and bodies, and to the medical profession.

And further to inquire into the result of "The Medical Act, 1858," and the Acts amending the same, and into all matters dealt with by those Acts.

Now know ye, that we, reposing great trust and confidence in your knowledge, discretion, and ability, have authorised and appointed, and do by these presents authorise and appoint you, the said Robert Adam Philips Haldane, Earl of Camperdown, William Connor, Bishop of Peterborough, William Henry Ford Cogan, Sir George Jessel, George Sclater-Booth, Sir William Jenner, John Simon, Thomas Henry Huxley, Robert McDonnell, William Turner, and James Bryce, to be our commissioners for the purposes aforesaid.

And for the better effecting the purposes of this our commission, we do give and grant unto you, or any three or more of you, full power and authority to call before you, or any three or more of you, such persons as you shall judge necessary by whom you may be the better informed of the truth on the subjects herein submitted for your consideration, and every matter connected therewith; and also to call for, have access to, and examine all such books, documents, papers, and records as may afford the fullest information on the subjects of this inquiry; and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And our further will and pleasure is that you, or any three or more of you, do report to us, with all convenient speed, under your hands and seals, the result of your inquiries into the above matters, and what amendments are required in the above-mentioned Acts, and what provisions it is expedient to make in the matters above-mentioned, or any of them.

And we further will and command, and by these presents ordain, that this our commission shall continue in full force and virtue, and that you, our said commissioners, or any three or more of you, may from time to time proceed in the execution thereof, although the same be not continued from time to time by adjournment.

And for the purpose of aiding you in such matters, we hereby appoint our trusty and well-beloved John White, Esquire, Barrister-at-Law, to be Secretary to this our commission.

Given at our Court at Saint James, the thirtieth day of April, one thousand eight hundred and eighty-one, in the forty-fourth year of our reign.—By Her Majesty's Command,

W. V. HARCOURT.

THE LANCET.

LONDON: SATURDAY, MAY 7, 1881.

A Royal Commission has been appointed to investigate the working of the Medical Acts, and, at length, consider the necessity for amendments of them. The following is the list of names as they appeared in *The Gazette* of Tuesday last:—The Earl of Camperdown, the Bishop of Peterborough, Right Hon. W. H. F. Cogan, the Master of the Rolls (Sir George Jessel), Right Hon. G. Sclater-Booth, M.P., Sir William Jenner, Bart., M.D., J. Simon, Esq., C.B., Professor Huxley, Dr. Robert McDonnell (Dublin), Professor Turner (Edinburgh), J. Bryce, Esq., M.P., with John White, Esq., Barrister-at-law, as secretary. Our readers will remember that when it was first announced that such a Commission would be appointed, it was given out that it would include no medical men. This determination altogether surprised and disappointed us. It was quite evident that a Commission without medical men on it would be in a fog from beginning to end of their work, unable to extract facts from the various witnesses, and equally unable to use the information elicited. We lost no time in showing this and in pointing out that a Commission so constituted would be obliged to seek some medical guidance, and would naturally seek guidance of the Medical Council, one of the bodies whose administration is complained of by those who are best able to judge. We have reason to believe that our arguments had weight in convincing many, members of the Government included, that medical men ought to be added to the Commission, for the double reason that they were deeply interested in medical legislation, and that they were most capable, by reason of their knowledge of the technical and complicated nature of the questions, of seeing and assisting others to see the points really at issue, and getting at the truth touching the working of the Medical Council and of the various examining bodies. When it was once determined to appoint medical men, it became a question how they were to be selected? Obviously it was not to be thought of that only such gentlemen as were known to be favourable to, or actual members of, the Medical Council were to be put on the Commission. Some names representing independence, and a knowledge of the educational questions involved, were required to satisfy the public and the profession. The names chosen will have this effect. It is to be regretted—seeing that the questions to be settled have reference chiefly to general medical practice in its broadest sense—that the Government have not seen fit to appoint a Commissioner familiar by experience with the present position of the general practitioner, and his relation to the public. But the profession will be well content to be represented by Sir William Jenner and by Professor Huxley. The too scanty representation of the profession on the Commission will naturally lead medical practitioners to look to Sir William for the thorough investigation of questions which it is important to have settled. They will, we believe, not look in vain, and meantime we will accord our own thanks to him for agreeing—at what must be great personal sacrifice and inconvenience—to accept so important a duty. Sir William was once a general practitioner, and though now moving in the highest spheres of consulting practice, is always showing his sympathy with those who are doing the hard work of common practice, in which work, too, he laid the deep foundations of that practical sagacity and knowledge of disease which now qualify him so well in guiding his brethren. He is well known also to believe that the existence of a Medical Council with no representative of the medical profession in it is one of the greatest anomalies. Professor Huxley will look at the questions which come before the Commission from a somewhat different standpoint from that of the medical practitioner, but he will not be out of sympathy with him; and we shall be greatly disappointed if his influence is not used to simplify examinations, and to make the education that precedes them more thorough and more effective. Professor Turner and Mr. Simon are members of the Medical Council; but the one represents such an enormous medical school, and such an efficient university, and the other is so able a medical statesman, and withal so anxious to make the Council worthy of the respect of the profession, that we cannot but commend the judgment of the Government in appointing them. The other members of the Commission will come to their work with various, though not medical, qualifications. An improvement in the Medical Boards and the Medical Council is an object of the widest interest to the public and to all classes. Politicians and statesmen may be apt to say this is solely a public question, and has nothing to do with the interest of the profession. We shall trust any body of educated men, and certainly this Royal Commission, to avoid such a narrow view as this—as if it were possible to dissociate the interest of the public and that of the profession on which it is most deeply dependent. The questions to be investigated and the problems to be solved by this Commission must form the subject of earnest consideration. We accept the appointment of the Royal Commission as an evidence of good faith on the part of the Government—not, as some would have us regard it, as a device for shelving or indefinitely postponing a great question, but as a means of establishing the profession in the esteem of the State, and securing to its members the possession of those rights which are the only set-off against the severe exactions and duties which are imposed on them by law and by the nature of their relation to the public. We publish in another column the terms of the Reference for this inquiry, as set forth in the Royal Commission, dated April 30th, 1881.

◆

What are euphemistically called "accidents" in lunatic asylums can scarcely be held to be numerous, when we consider the great total population of the insane; its unequal distribution; the relatively small number of attendants employed to maintain order; and the large amount of personal liberty now commonly accorded to persons who are either incapable of self-control, or—to their own knowledge—absolved from the duty of restraining their impulses by the fact of being "under certificate." Probably the aggregate return of assaults committed in an equal population of sane persons, of the same heterogeneous character as this multitude of so-called "lunatics," living for the most part idly, under lax, and daily relaxing discipline, and being as well fed as they are, would *exceed* the gross total of those scenes and acts of violence which have lately attracted public attention, and gone far to produce a wrong and unfair impression of the general excellence of our asylum management. We believe, not without the power and opportunity of forming a judgment, that the superintendents of institutions for the care of the insane are maligned when it is supposed or assumed that they are in any way responsible for these occurrences. The responsibility—so far as there can be said to be any—lies with the attendants, and with the "insane" themselves. If attendants were only a little more watchful, and lunatics would not let their angry passions rise at the smallest provocation, things might go on quite pleasantly. As it is, the reputation of really deserving establishments is damaged, and an objectionable—we may be excused for saying hateful—subject is again and again thrust under public notice, without the smallest necessity, and of course without any good result. We are aware that the inmates of asylums, both sane and insane, read all that is written about them, being much interested in several burning questions recently and now under discussion in the professional and lay journals and newspapers, and we think t expedient to speak plainly. An asylum for the insane ought, under the benign influence of the system extant, to be at least as peaceful as the model zoological institution in the Regent's-park, whereas we too often find its amenities sinking to the level of those which prevail in a vulgar caravan.

The modern lunatic asylum and the Zoological Gardens of fashionable resort are conducted nearly on the same principle and with the same objects—namely, to keep the wild animals in a state of comparative tranquillity and with safety to the public, while affording opportunities for the study of the classes of life to which the *feræ* belong or which they are supposed to illustrate. The wild men and women are not at present chained to the walls or kept in cages as they used to be. Outside pressure has been brought to bear on the keepers of asylums during the last half of the century, and the inmates of these establishments are now allowed to walk about like the members of a "happy family," being kept from injuring one another by means identical with those adopted to keep up appearances in the improving street show of mingled cats and birds and mice—namely, the coercive force of fear and kindness, tempered by bribery and favouritism. In the enterprise thus carried out the keepers of asylums generally are meeting with a large measure of success. A tour round the public and the private institutions for the insane throughout the country would not perhaps prove an amusing, but it could not possibly be deemed a revolting, excursion for the humane sensation-seeker of either sex. It would probably result in disappointment, except to the initiated student of types of insanity and idiocy, because there is little positively exciting to witness. The mournful jingling of chains has been eliminated from the entertainment, and where there are locks they are well oiled and the keys turn easily. For the rest, quiet reigns, where years ago there was hideous turmoil; decent dresses replace the rags of the raging maniac; and—which is the greatest trophy of recent success in the treatment of the insane—they are now to be seen dancing solemnly to festive music, or sitting patiently, if not enthusiastically, in melancholy rows, while their protectors amuse themselves with theatrical performances. Altogether, as we have said, the scene presented at any average specimen of our well-conducted asylums—and all are well conducted now—is of a nature to allay anxiety as to the care, of the insane. Then why should public opinion be disturbed because every now and again it hears of "accidents," which are not either more numerous or more serious than the "accidents" of ordinary life among the sane? It is impossible for us to feel anything except pity for the poor folk who "do not understand" these things, and so give way to feelings of indignation when they hear of the accidents and misadventures which occur, and we cannot withhold our sympathy from the enterprising managers of asylums, who are misrepresented by the character these occurrences seem to give the institutions under their control.

There is, however, another aspect of the case which cannot be wholly shut out of sight or forgotten when the unpleasing incidents of asylum life are thrust under notice side by side with tokens of peace and comfort, and even of enjoyment. In theory, at least, lunatic asylums are hospitals for the *cure*, not simply retreats for the *care* of the insane. Is the first mentioned, and we take leave to say the only *professional*, object kept steadily in view, or is it not rather allowed to fall almost out of remembrance? In the rage to rob asylums of their disagreeable character they have been swept and garnished and their inmates have been clothed; but with these triumphs of humanity the philanthropist rests content! Little, if anything, is done to restore the sufferer from mental disease to his right mind. It is not too much to say that the inspiring genius and system of modern improvement have for their motive and key-note the hypothesis that insanity is always dependent on organic disease, and therefore rarely, if ever, curable. It does not require any large amount of experience, or a very high degree of acumen, to recognise that under the influence of a belief so enervating as this must be, scarcely anything is done, or expected to be done, for the active and personal treatment of the cases of insanity "huddled" together in asylums. Nor are the inmates of these institutions in a much worse plight in this respect than the victims of mental disease in private families. There is practically no such thing as "treatment" now-a-days. The most that is done anywhere is to place a patient under what are deemed to be favourable circumstances, amid pleasant surroundings, and to leave the rest to nature. It is true drugs are given—to produce quiet, to relieve pain, to stupefy those who are unable or unwilling to sleep, to allay paroxysms of excitement which disturb the wards of an asylum or occasion distress in a household. Beyond this, however, little or nothing is done except to treat the physical maladies of the insane, and to try the effect of such drugs as come, recommended to the notice of the asylum physicians of England, from the Continent and the United States. For ourselves we are lying on our oars, and amusing our leisure with theatrical entertainments while we bask in the sunshine of a high reputation for the advanced humanity and philanthropy we manifest in our management of the insane. The picture presented is more creditable to the "keepers" of asylums than to the professional enterprise of the physicians and practitioners engaged in what is called "psychological medicine."

The real cause of "accidents" in lunatic asylums is the fact that their inmates are not treated as patients, but as pensioners or boarders. There is little or nothing personal in the treatment they receive. How can there be, when to give only half a minute to each case would make a routine round of the wards last some five hours, at least? When this argument is pressed on the attention of Committees of Justices and medical authorities, we are asked to look at the class of cases which form the bulk of an asylum population, and to say what proportion of these could possibly be benefited by any amount of time or attention bestowed upon them. As a matter of fact, we believe, new and practical light would be shed on the actual, as distinguished from the "assigned," causes of insanity if these seemingly uninteresting cases were more closely studied than they now are. It is disheartening to go round asylums and notice how little attention medical men who enjoy the largest opportunities of observing the progress of what are now deemed "uninteresting" and "incurable" forms of disease give to them, and how little use they make of the rich and abundant material at hand. Let that pass, and we will admit that the proportion of obviously "curable" cases in the great majority of asylums is exceedingly small. Five per cent. of the whole would be an excessive estimate in many, if not most, large institutions. It must be granted that this represents a state of matters which is essentially demoralising. Even good and earnest men inevitably lose heart in the midst of misery which they are not so much unable to relieve, as prevented by the circumstances and conditions of their practice from even attempting to benefit! The result is that in most cases matters are allowed to drift; and, except for the interest displayed in a few show cases and an occasional outburst of energy in the trial of some novel expedient suggested for the relief or remedy of a special form of disease, nothing medical is done or contemplated. Quiet wards and uncomplaining patients are the most satisfactory results obtainable, and for these superintendents, lessees, and managers are dependent on their subordinates. They cannot, as a rule, afford to pay attendants very highly, or to employ a sufficient number of them to keep the inmates of asylums under continual protection of the most perfect sort. It follows that accidents must every now and again occur; the only occasion for wonder is that they are not more numerous and grievous than those reported. The sole remedy for the existing state of matters, with its inevitable consequences, is a complete change of the whole system of lunacy practice, a reform which shall convert asylums into hospitals; but for this change neither public nor professional opinion seems to be as yet ripe. Until the medico-economic view taken of insanity, as a class of disease and a burden on the community, has undergone a sweeping change, we must put up with the *status quo*, and—except for the neglect of opportunity, the needless perpetuation of hereditary disease, and blind persistence in carrying a weight which might be greatly reduced,—there is actually little of which to complain.

◆

OBSERVATIONS which have lately been published seem to demonstrate almost conclusively the association of bacterial organisms with the process of typhoid fever. VON RECKLINGHAUSEN, in 1871, first noted the presence of micrococci in points of suppuration in that disease, and this observation was corroborated in the following year by EBERTH; but the organisms were regarded as connected with a secondary pyæmic process rather than with the primary disease. The description by KLEIN, in 1875, of abundant micrococci in the intestinal follicles received less attention than it, perhaps, deserved, on account of the doubt which was afterwards expressed by himself regarding the accuracy of some of his conclusions. SOKOLOFF found micrococci in the spleen in only three out of twelve cases, and conjectured that they might be due to the necrotic process in the intestine. FISCHEL, in 1878, found the organisms in the spleen in fifteen out of twenty-nine cases, and still more frequently in the lymphatic glands. EBERTH, in a paper published last year, describes a series of observations in which he found bacilli in eleven out of twenty-three cases. Rod-like bodies were abundant, about the same in size as those which are met with in decomposing blood, but differing from them in shape, and very strikingly in the slighter degree with which they are tinted by methyl-violet. They appeared to be identical with those described by SOKOLOFF and FISCHEL. They differed also from the organisms associated with pyæmia. Their occurrence bore no relation to the time which had elapsed after death, and they were more frequently found early than late in the disease. Their localisation was also different from that of the organisms in pyæmia. The latter are found in the blood-vessels of various organs, but the bacilli in typhoid are found only in the spleen, intestinal follicles, and lymphatic glands. In a more recent communication to VIRCHOW'S *Archiv*, EBERTH describes some further observations on the same subject. In seventeen other cases of typhoid, the bacilli were found in six, were absent, or at least were not discovered, in eleven. The changes in the intestine and glands were more recent in the positive than in the negative cases. The organisms were precisely similar to those met with in the other series. EBERTH has also examined a large number of cases in which death occurred from other diseases, but in none did he find this organism. The same bacillus was also found last year in cases of typhoid by KLEBS. Its special character and frequent occurrence leave little doubt that it is in some way connected with the disease. Whether it is actually the vehicle of, or constitutes, the contagium, can only be decided by further experimental investigations. For these we must wait; but meanwhile some important observations have been published in the last number of VIRCHOW'S *Archiv*, by Dr. BRANLECHT, on the presence of "pathogenic" bacteria in the drinking-water during epidemics of typhoid. The organisms consist of rods, filaments, and micrococci, and if the water containing them was allowed to stand at a warm temperature, they formed a scum on the surface. It was readily cultivated in organic solutions, that employed being a solution of gelatine containing a little phosphate of ammonia. The rods and filaments were twice as thick as the bacillus found by KOCH in septicæmia, and half the size of bacterium termo. Its action on the culture-solution was found not to be of the powerful deoxidising character peculiar to some bacteria, and no fetor arose during the growth.

After culture, if the liquid be distilled, the distillate is neutral in reaction, and the first part contains a body capable of producing pyrexia, but which loses this capability on prolonged exposure to heat. These bacteria are very sensitive to acids; if the gelatine possesses the faintest acid reaction, they will not grow, and alkalinity is similarly but in a less degree inimical to them. In water which is kept at the ordinary temperature the growth of the bacteria is extremely slow, even when they are abundantly supplied with their ordinary nourishment. Nevertheless they do multiply, and, what is equally important, they preserve all their properties, including their pathogenic power, for at least nine months. BRANLECHT has found the same bacteria in the urine of a man suffering from typhoid fever. Micrococci were chiefly present at the height of the fever, but they were accompanied by a considerable quantity of rods and filaments.

The same organisms were also found in a quantity of green algæ which was decomposing, in very hot weather, in a district at the time perfectly free from typhoid fever. Culture and experiment on animals demonstrated the identity of this form of bacteria with that already described. An injection of the decomposing material into a rabbit caused an intense necrosis of the intestinal glands, such as was not seen with the cultivated bacilli. BRANLECHT throws out the suggestion that in such decomposing vegetable matter this organism may perhaps take its origin—that is, be produced by a transformation from some allied organism. He notes as curious that during culture another organism often appeared, having a diameter twice that of the first, and not possessing the same pathogenic properties. He is inclined to regard it not as an accidental contamination, but as a special form of growth, which, when it attains a certain proportion, renders the culture innocuous.

The injection beneath the skin of a rabbit of a centimetre of the culture-solution causes a slight rise of temperature, amounting sometimes to a degree and a half Centigrade, which lasts eighteen or thirty-six hours; and then, in spite of abundant food, and usually without diarrhœa or pyrexia, the animals gradually emaciate, until in two, four, or eight weeks they are reduced "to a skeleton." In those a few weeks old abundant diarrhœa is produced, causing death at the end of a few days, with merely the signs of congestion of the stomach and intestine. In the older animals there is found an intense catarrh of the small intestine, swelling of the mucous membrane, and enlargement of Peyer's patches, with considerable increase in size of the spleen and of the mesenteric glands, especially in the neighbourhood of the cæcum. There was never any considerable irritation at the point of injection. The introduction of the masses which resulted from culture, with as little as possible of the culture liquid, gave nearly the same results. Infection by the stomach could not often be produced, but in the successful cases there was considerable diarrhœa as well as symptoms identical with those presented by the animals infected by the subcutaneous method. Prolonged culture caused no diminution in the morbific power.

The coincidence of the occurrence of this bacillus with epidemics of typhoid fever is certainly remarkable; and the experiments show, at any rate, that, just as well-water may contain innocent bacteria, it may also contain such as, injected into animals, cause an acute illness having some of the characteristics of typhoid fever. It is of great importance to ascertain whether this organism is, as seems probable, identical with that found by KLEBS and EBERTH, but for this purpose it will be necessary to compare them under similar conditions of artificial cultivation.

WE have little further space to devote to the proceedings of the Medical Council at its late meeting. There was practically little else to do than erase a name from the Medical Register, to counsel the Educational Bodies with reference to the times of holding their Preliminary Examinations, and to partially undo the work of last year in the matter of recommending the institution of a Preliminary Scientific Examination. The answers of all the bodies are not yet to hand, and the Council has postponed the application of its recommendation, with a mild request to the various bodies to consider how such an examination could be realised. In the last year or two the income of the Council has been in considerable excess of its expenditure. Generally the balance is very slight. But in 1879 and 1880 it was respectively £961 10*s.* and £1568 1*s.* The dental business of the Council does not promise to bring profit to the Council any more than it has brought credit. There was an accumulation fund of £10,000 from the first registrations, but Dr. QUAIN, the chancellor of the exchequer for the Council, estimates that, whereas the estimated annual expenditure on the dental registration will be £1407, the estimated income will be only £524, leaving a deficiency of £883! This is verily a poor business!

Annotations.

"Ne quid nimis."

THE PRELIMINARY SCIENTIFIC EXAMINATION.

IT will be remembered that at the meeting of Convocation of the University of London on January 13th, 1880, a resolution was unanimously passed to the effect, "That the Senate be requested to consider whether it would not be desirable that in future the Preliminary Scientific and First M.B. Examinations should be held twice annually." The doubling of an examination is not so easy a matter as it appears to those who know nothing of the ways and means and arrangements of the University, but nevertheless the Senate (always ready to consider the suggestions and recommendations of Convocation) consented to entertain the idea, to begin with, of doubling the Preliminary Scientific, at which examination the number of candidates shows a disposition to increase rapidly, and a sub-committee of the Senate who investigated the question admitted its desirability. The various medical schools were informed of the proposed change, and the opinion of the medical teachers in London and the provinces was asked upon it, with the result of showing an almost complete unanimity in its favour. Opposition has, however, been offered to the proposed change by some of the science teachers of London, who have memorialised the Senate, and have urged that the holding of two examinations in the year would be unnecessary and injurious to regular study; because (1) the necessary abandonment of separate honours examination would discourage the development of scientific tastes in medical students; (2) it would disorganise the present (or any efficient) course of study; and (3) there would be a difficulty in securing examiners with the necessary qualifications. On the receipt of this memorial, the matter was referred back to the Annual Committee of Convocation, who appointed a sub-committee to reconsider the question. The result has been that both the sub-committee and the Annual Committee have upheld the opinion expressed by Convocation on January 13th, 1880, and at the meeting of Convocation to be held on Tuesday next (May 10th) Convocation will be asked to reaffirm its opinion by passing a resolution to the effect that it is desirable to hold the Preliminary Scientific Examination twice in the year.

This seems to us a matter of no small importance to the medical teachers and students of London. It is clearly a subject which concerns the medical profession, rather than the teachers of science, and we believe the objections raised by the scientific memorialists to be purely imaginary. The University of London is practically the only university at which the London medical student can obtain a degree, and it is but mere justice that every facility should be afforded him for doing so. We believe that the great obstacle to obtaining the London degree is the long time which is necessary, a time which, in case of failure at any of the examinations, becomes oppressive to many by reason of the expense. We have, in fact, pointed out in these columns that the percentage of rejections at the College of Surgeons is greater than it is at the analogous examinations of the University, and we believe that if the Senate of the University can manage to carry out this much-needed reform, we shall no longer be scandalised by the yearly exodus of hundreds of Englishmen across the Scotch border. As there may be some opposition to the resolution which Convocation will be asked to adopt, we trust that medical graduates will make a point of being present. The resolution will be moved by Dr. Poore and seconded by Dr. Curnow, who had charge of it on the previous occasion, and as it is the first business on the agenda-paper after the presentation of the report members should be in their places by five o'clock.

THE SMALL-POX QUESTION.

THERE is happily—as a matter of chance and of good fortune—a slight decline in the apparent ravages of that most easily preventable of all diseases, small-pox. This is a matter of thankfulness, though certainly not of self-gratulation, as we are practically doing nothing to stem the progress of the malady. Meanwhile, several phases of the grave medico-economic question raised by this epidemic must be thoroughly discussed. The great pressure on our columns this week—caused chiefly by the verbose and valueless "proceedings" in the Medical Council—compels us to defer the discussion until our next. Dr. Cameron, the member for Glasgow, has an article in the May number of the *Fortnightly Review* on the question, whether "vaccination," as commonly practised, is degenerating; and the chief medical officer of the General Post Office makes a special report on the subject of "Revaccination." These and other contributions to the general controversy call for special comment, which we are obliged to postpone. The continued ventilation of this subject must weary the medical reader; but the public interests involved are so vast that it cannot yet be set aside, although professional opinion is sufficiently informed and clearly formulated.

MICROGRAPHIC TRACINGS.

M. MAREY described at a meeting of the Académie des Sciences on April 18th an ingenious modification of the method of the graphic record of phenomena, with which his name is so honourably associated. In many physiological tracings it has been thought that some of the curves supposed to be of significance may possibly have been the result of oscillations of the lever. It seemed, therefore, to M. Marey desirable to remove this doubt, and to demonstrate the fidelity of the instruments by showing that identical tracings may be obtained by other instruments which cannot be affected by this cause. This result has been attained by making the scale of record extremely small. If, for instance, the tracings of a sphygmograph are five millimetres high, it is possible that the lever may in its rapid movement go too far before the friction arrests it. If, however, the amplitude of the movement is reduced to one-tenth, the effect of the momentum of the lever will be reduced to one-hundredth (the square root) of that which it possessed in the former case. But in order to preserve the form of the trace, the surface on which the lever writes must move very slowly, not more than one millimetre per second. The details of the curves thus obtained will not be visible to the naked eye, but if placed under a microscope, and magnified twenty diameters, their form can be plainly seen. This method of record has another advantage. Donders has remarked that a recording apparatus is only accurate for movements of a certain rapidity, for which it has been constructed, and if it is made to record movements of much greater rapidity they are not accurately represented. But the microscopic inscription multiplies almost indefinitely the field of work for the graphic method, by obtaining a sufficiently fine steel point to write and a black layer thin enough to receive the tracing. M. Marey has already succeeded in receiving and registering the movement of a tuning-fork vibrating 200 times per second, and in recording the vibrations of a voice singing at one end of a tube. Even the vibrations of blood in a vessel, which causes the "bruit de souffle," seem to be among the movements which can be recorded. At least, in the case of elastic tubes and artificial aneurisms, M. Marey has succeeded in recording the vibrations produced by a current of water, and which are also audible. A possible source of error in this method, which must not be overlooked, is the friction of the style against the glass. Momentum and friction are two sources of possible error in all tracings. The former augments with every increase in the range of movement of the lever, the latter with every decrease, and special care will be necessary to reduce the friction to a minimum to avoid this error.

THE PHYSICAL DETERIORATION OF THE ENGLISH PEOPLE.

IS it a fact that the Anglo-Saxon race is in slow process of physical deterioration? Such is the opinion of Mr. Horsfall in a letter addressed to the *Manchester Guardian*, arising out of a statement by Dr. Beddoe and Mr. Tuckett that "British heads are smaller than British heads used to be." He points out that the conditions under which the youth of the country are brought up in these days are such as to favour the development of a stunted race. No playgrounds, no public gymnasia, and an enforced resort to early drinking and smoking are the main factors at work, according to this authority, in the production of a general enfeeblement, unknown in the freer and robuster times of old. And there is, it must be admitted, considerable truth in the argument. With all our endeavours at improved sanitation, there remains much to be done in the way of physical education, and the gospel of a healthy body which shall be capable of all the demands made upon it needs to be strenuously preached and acted upon in the interests of the nation. The mode of life of a great number of our urban population is *the* great evil of civilisation. Deprived of fresh air and healthy exercise, combined often with an improper and an inadequate supply of food, and a consequent resort to artificial stimulants, such people are growing up under conditions which can only lead to one result, that of defective development. For our own part we heartily endorse the suggestion made by Mr. Horsfall, that places of open-air recreation and gymnasia should be vastly multiplied, and access to them obtained even on that day of the week termed a "day of rest," but which is too often a day of idleness and dissipation. We sadly want in this matter the exercise of that common sense which has usually been regarded as the peculiar feature of the British character, but which in some matters is kept wholly in the background, and never asserts itself.

CONVERSAZIONE AT THE MEDICAL SOCIETY OF LONDON.

THE usual conversazione held at the close of the session of the Medical Society took place on the 2nd inst., and was well attended. It was preceded by the delivery of the annual oration by Mr. Arthur Durham, which was quite worthy of the occasion. The orator chose for his subject the Surgery of the Future, not, as he remarked, meaning thereby the remote future, when the need for surgery might cease to exist entirely, but the immediate future. The subject was happily chosen and cleverly expounded, comprising the topic of cancer, which Mr. Durham showed from the Registrar-General's returns to be steadily on the increase. He pointed out the paramount necessity of early recognition of this direful disease, and of its prompt and effectual removal by the knife, which should not be sparingly used. He cited cases from his own experience where many years' immunity from recurrence had been enjoyed by the recognition of these important facts; but he admitted that underlying the local manifestation of cancer there was a constitutional tendency, which must be dealt with if cancer were ever to be eradicated or its increasing mortality controlled; and he appealed to physicians to seek for some remedies which should have as marked an effect in this disease as iodide of potassium has in syphilis. Turning to the subject of abdominal surgery, he spoke chiefly about operations upon the kidney, and related a case he dealt with in 1870. The patient was a young woman who had all the symptoms of renal calculus in an aggravated degree, whose life was rendered intolerable on account of pain in the loin, who had hæmaturia and attacks of vomiting, and who was known to have passed gravel. Under these circumstances, and after consultation, Mr. Durham explored the kidney, but found no calculus; the operation, however, afforded some months' relief. Then with return of the symptoms he ventured to remove the kidney, which presented a normal appearance. In a few days the patient unfortunately died, and the cause of death was not cleared up on post-mortem examination; indeed he could not help thinking that fright had something to do with the untoward issue of the case. He referred to Mr. Morris's case, where after a similar diagnosis a calculus was found and successfully extracted, and pointed to this as an encouragement for a procedure which, however, might not often be required. Nephrectomy was now being much more frequently performed; and Mr. Barker's statistics were quoted to show that the mortality after this formidable operation was not by any means excessive considering its nature, and the nature of the diseases for which it was undertaken. Other abdominal operations, such as gastrostomy, excision of the pylorus or stomach, and operations for the relief of intestinal obstruction, were noticed; and the importance of the early performance of the last-named strongly insisted on. Want of time prevented him taking up all the points in which the field of surgery was being enlarged, but he concluded by some interesting remarks upon antiseptic surgery, humorously deprecating the title "antiseptic," as if all surgeons who did not carry out its details were "septic," and comparing the phraseology to that of the "homœopaths," who regard those who do not pursue their lines as being devoid of science, or "allopathists." He warmly eulogised Mr. Lister's labours, and held that the practice of "antisepticism" was perfectly distinct from the acceptance of the germ theory, which had been useful as enforcing attention upon the methods employed, and he summed up the advantages and disadvantages of the "spray" in a practical and convincing manner. Altogether Mr. Durham's oration was considered to be a success; the subject was a well-chosen one, and travelling over a wide field upon matters which are at the present time most inviting attention in the surgical world, it was interesting and suggestive, and a cordial vote of thanks, proposed by Dr. Broadbent from the chair, was carried by acclamation.

CHARCOT ON HYPNOTIC CONTRACTURES.

THE strange phenomena of hypnotism are elicited with readiness in the subjects of hysteria, and have been for some time the subject of special study at the Salpétrière by M. Charcot. His latest investigations (described at a recent meeting of the Société de Biologie) have been chiefly directed to the phenomena of muscular contracture, which is readily obtained by the mechanical stimulation of the tendon, of the motor nerve, or of the substance of the muscle, so that it can readily be localised in a single muscle or group of muscles. This contraction is very intense, and fixes the limb in a given attitude with a force which cannot be overcome even by energetic efforts. When the hand is closed thus it cannot be opened by any force which can be applied to it. Nevertheless, it can be at once relaxed by mechanical stimulation of the antagonists, such as is afforded by gentle rubbing of the extensors of the hand; the fingers are at once extended, and the contracture disappears as if by enchantment. If the contraction is not thus relaxed, when the patient is awaked one of three things may happen. (1) The contracture may disappear, the patient recovering, with consciousness, the liberty of all movement. (2) If the patient is rendered cataleptic the contracture may continue after the awaking, being, as it were, fixed by the catalepsy. (3) In some cases the contracture persists, although the patient is not rendered cataleptic. The patients who preserve the contracture after the recovery of consciousness present the closest resemblance to hysterical patients affected with permanent contracture. Friction of the antagonists is powerless to resolve it. A magnet applied near the fixed limb only increases the contracture, but applied to the opposite limb it causes the curious phenomenon of the transfer of the contracture. This changes its place to the opposite side, but does not yield to the magnet. To remove it the patient must be again placed in the hypnotic state, when the stimulation of the antagonists suffices to make it disappear. In most cases the change of contracture occurs in all the muscles of a limb, but it has also been found that when only a few muscles are affected by the contracture, the transfer involves exactly the same muscles of the opposite side; and this is true however the first contracture may have been brought about. Anæmia of a limb, such as is produced by Esmarch's bandage, hinders the development of the neuro-muscular hyper-excitability, as Brissaud and Richet demonstrated. If, for instance, a limb is thus treated, the patient hypnotised, and the muscles of a limb are rubbed, no contracture is induced; but as soon as the current of blood is restored the contracture occurs, without any further stimulation. Hence it seems that in the anæmic limb there is a sort of potential contracture. The impulse is received by the nerve centres, and is preserved there until the re-establishment of the current of blood, restoring to the muscles the ability to contract, permits it to manifest itself. This latent contracture may be transferred by the magnet from one limb to another on the opposite side, just as may be the developed contracture. As an illustration of the method of obtaining these results an instance is described in detail. The patient, having been hypnotised, is in a state of lethargy, with muscular hyper-excitability; but it would not do to apply Esmarch's bandage while she is in that condition, because the mechanical stimulation would probably cause a contracture of the whole limb. The patient's eyelids are therefore raised. She at once becomes cataleptic, the limbs retain any position in which they may be placed, but the muscles have ceased to be sensitive to mechanical excitation. Advantage is taken of this loss of excitability to apply the bandage. The eyelids are then pressed down. The catalepsy at once ceases, the patient resumes the condition of lethargy and the muscles recover their excitability. Then, without touching the limb elsewhere, a small button is pressed several times against the ulnar nerve behind the elbow. No effect follows until the bandage is removed, and then, as the blood returns to the limb, the hand slowly assumes the position due to contracture of the muscles supplied by the ulnar nerve, especially the interossei. In this experiment the excitation of the ulnar nerve has impressed the nerve centre in a peculiar way, but only in the parts corresponding to the ulnar nerve. The nerve action for the contracture in the muscles supplied by the nerve takes place in the nerve centre, but not in the periphery until the return of blood to the muscles restores their contractility. Again, the patient being asleep, the arm is anæmiated. The ulnar nerve is then stimulated, of course without effect. Nevertheless, the spinal cord has been influenced, and if the circulation were to be restored the contracture would come on. But if, instead of this, a magnet be applied to the other arm, the contracture is produced in this in exactly the same way as if it were actually transferred from the first side. The lateral contracture has been transferred. These phenomena, in the opinion of M. Charcot and M. Richer, are evidence of the reflex nature of the neuro-muscular hyper-excitability, whether produced by the mechanical stimulation of a nerve, a muscle, or a tendon.

REPORT OF DR. JAMES DOUGAL ON THE FASTING GIRL AT CHAPELTON.

DR. JAMES DOUGAL, C.M. Glasg., of Strathaven, has favoured us with the following account of this case:—

Christina Marshall was born in the village of Chapelton, Lanarkshire, in the year 1867. While from her father she could only inherit a vigorous and robust constitution, by her mother she could fall heir at least to a system generally weakened, and probably specially tainted, from the fact that the building up of that system was coeval with the development of a pulmonary phthisis which six years later left her without the care of a maternal parent. The family, of which she is the third youngest, consisted originally of nine members. Two have died of consumption, and one of scarlet fever. The remaining six can by no means be classed as hardy, but have as yet shown no decided tendency to the development of the undoubtedly family weakness, and of those six our patient is decidedly the least strong. They have been provided for through the exertions of the father as a road surfaceman; and, on the whole, the upbringing has resulted comparatively favourably, alike bodily and mentally, in the case of Christina. As regards her personal history I am told that, when three years old, she was the subject of a rather peculiar ailment, which was the more noticeable as it evidenced itself in the development of a strong craving for sugar, and an equally strong aversion to what had previously been her staple diet. This condition of matters lasted nearly three months, and life was maintained solely by the administration of beef-tea. This is certainly a most important historical item, seeing that we are now confronted with similar but much more pronounced symptoms. From the age of three onwards till last May no incidents particularly bearing on the present phase of the case have been discovered. Her condition during those years may be best described by saying that she was tender to rear, often a little unwell, seldom seriously. Her parents had never been made aware of any development of the seeds of consumption. She had phlyctenular ophthalmia, which left a considerable dimness of vision, and she had further been frequently harassed with severe attacks of headache, probably gastric in their origin. Owing to these complaints her attendance at school was broken, but the periods of absence were of usually short duration. She was considered an intelligent girl, was possessed of a disposition which was above the average in its liveliness, while it was properly tempered with a quiet and becoming thoughtfulness, to which the term melancholy could at no time properly apply. Exactly a year ago she contracted a cold, and this showing no signs of leaving her, I was asked to see her about the middle of July. I then found her suffering from a moderate attack of bronchitis, and I was pleased to be unable to detect any phthisical element in the case. From this she recovered in the course of ten days, to be immediately tortured with a severe headache, which has continued more or less ever since. During the autumn she was able to be out a good deal, but towards its end a great change came over her disposition. She now seldom spoke, almost never except when questioned, and she maintained a stolid and morose cast of countenance. She became very averse to all kinds of food, extremely constipated, and very sleepless; and I saw all those symptoms gradually but firmly and surely establishing themselves as part of her existence. For some weeks previous to December she went less out of doors; on the 20th her outing only lasted a few minutes, and it was her last; and on the 8th January she lay down on the bed, which she has never since quitted. Eighteen weeks ago last Sabbath she took a small piece of fruitcake; since then her parents distinctly and firmly assert that no food of any description has been taken by her. She takes water freely, and occasionally sweets, but obstinately refuses to be tempted by even the pressing and kindly entreaties of her father. When earnestly appealed to she begins to cry, and says she would like to take something, but can't swallow; and if deluded into taking a mouthful of water with a minute proportion of milk in it, she at once emits it. When reminded as to what must be the result of such a course, she says she has the inward feeling of approaching death, but that no possible efforts of hers are powerful enough to avert the fate which is slowly, but surely, enchaining her.—*Present condition:* Body very emaciated, but free from bedsores; complexion very sallow; lips pale and dry; tongue very red and dry; throat abnormally high in colour, and the seat of a choking sensation. On the cornea of each eye there is a nebula, the result of the ophthalmia. Headache constant and severe; continuous pain over stomach and bowels, increased on pressure; abdomen sunk. Lungs healthy, excepting the faintest suspicion of dulness on percussion over left apex. No cough; cardiac action weak, but sounds normal. She occasionally vomits a glairy fluid streaked with blood, and while the effort entailed leaves behind it great weakness it gives a transient relief to the gastric pain. Urine scanty, rather pale; deposits some urates, but is free from albumen. Bowels have not been moved for eleven weeks, and previous to that the intervals were six and seven weeks. At these times the motions were hard, dark, and small in quantity. She is quite unable to leave her bed, which is situated in the kitchen, and is quite removed from any, to her, possible source of food. This, in fact, her parents have now ceased to offer her. The only persons who see her are her father and stepmother, who alternately sit every night with her; a sister and brother, respectively eleven and eight years old, who stay in the house, and three older sisters, who visit her at rather long intervals. When I have mentioned these, and added the clergyman and myself, I have noted everybody who has any regular communication with her room. I omitted to mention that she has never menstruated. I have now given a minute report of this rather mysterious case. I have simply put on paper the results of my inquiries amongst her attendants, and added thereto my own medical examination of the case. I can vouch for the truth of none of the statements made to me by others, but I may fitly close my remarks by saying that I have known the father and stepmother for six years; that they are in easy circumstances; that I believe the honesty and integrity of their characters to be above the faintest tint of suspicion; and that I have never, in all my connexion with the district in which the girl resides, heard even the gentlest murmur of gossip pointing in the direction of latent channels of food-supply. My attendance on the case has been pretty close, and has now included a large number of visits, but I have not yet been able to formulate an explanation of the case satisfactory even to myself.

ENGLISH HEALTH IN THE WINTER OF 1880-81.

THE Registrar-General's Quarterly Return, relating to the three months ending March last, which has just been issued, completes the official record of the mortality in England and Wales during the winter of 1880-81. The death-rate among the English people in the two quarters ending December and March last was exceptionally low. In the last quarter of 1880 the annual death-rate was but 19·6 per 1000, and was 2·1 below the average rate for the quarter; only once since civil registration was established in 1837 has so low a death-rate prevailed in the fourth quarter of the year. In the first quarter of this year the death-rate was 21·8, and again 2·1 below the average; so low a death-rate has not occurred in the first quarter of any year since 1856. This low rate of mortality is especially noteworthy on account of the severe frost and intense cold that prevailed during a considerable portion of January. Indeed, the aggregate cold of last quarter was greater than that in the corresponding period of any year since the memorable frost of 1855. It would be interesting to inquire why the severe cold of last quarter did not cause the usual excess of mortality arising from such low temperature. The general tendency of the Registrar-General's recent mortality statistics point, however, conclusively to the improving sanitary condition of the country, and in the quarterly return just issued both infant mortality and zymotic fatality are reported to have been considerably below the average. Especially noteworthy is the recent marked and steady decline in the death-rate from "fever," mainly enteric. The fever death-rate was lower last quarter than in any previous corresponding period on record; the annual rate from this cause did not exceed 0·26 per 1000, whereas in the ten preceding corresponding quarters it averaged 0·48. Since 1870 the deaths referred to fever have continuously declined, and the death-rate recorded in the first quarter of this year is scarcely more than one-third of that which prevailed in the corresponding period of that year. It is not necessary to look further for conclusive evidence of the direct effect of the recent public awakening in sanitary matters. The return just issued shows that during the first quarter of this year small-pox prevalence and fatality was again practically confined to the metropolis. The deaths referred to this disease in England and Wales during the three months ending March last were 730, of which no less than 652 occurred in London and its outer ring of suburban districts, 12 in nineteen of the largest provincial towns, and 64 in the rest of England and Wales. Out of London the only fatality of the disease of an epidemic character occurred in Bury, where 24 fatal cases were recorded. The national health bulletin, supplied by the Registrar-General's last Quarterly Return, is exceptionally and unexpectedly favourable.

THE TRANSVAAL WAR: GALLANT CONDUCT OF MEDICAL OFFICERS.

THE Natal papers publish some interesting particulars of the gallant and heroic conduct of the Army Medical Officers who took part in the recent engagements with the Boers, two of whom perished in their noble efforts to succour the wounded on the field. We read in the *Natal Witness* that, at Laing's Nek, "Doctors Ring and Landon moved up behind the advancing column, and on its retirement remained, amidst a shower of bullets, attending to the wounded. At the final disaster, at Majuba Hill, the officers of the Medical Service remained faithful to their duties—even unto death. Dr. Cornish was shot as, with a piper of the 92nd Highlanders, he was carrying a wounded man on a stretcher that had been abandoned by the native bearers. Dr. Landon, always keen for duty in the field, and taking a special pride in his Army Hospital Corps, met his fate at the final rush of the Boers, as with a few of his men he was engaged in seeing to the wounded on the ridges. The ruling passion strong in death, he called Dr. Babington's attention, shortly before he expired, to the meritorious conduct of his men. And well he might; the conduct of some of the Army Hospital Corps orderlies was beyond all praise." General Sir Evelyn Wood has recommended that the highly prized Victoria Cross should be bestowed on Corporal Farmer, of the Army Hospital Corps, for his gallant conduct at the Majuba action. Corporal Farmer was attending to some wounded on the field, and at the approach of the Boers, although he had time to fly, he held up a white flag with his right arm, which was shot away; but exclaiming, "I've another arm left," he raised the flag with his left, and was again shot down; even then he remained with his wounded, giving all the assistance he was able. Sir Evelyn Wood characterises his action and conduct as of bravery deserving the highest reward. The Victoria Cross has seldom been more gallantly earned. In the *Gazette* despatches and enclosures from Commodore Richards, describing the part taken in the engagement by the Naval Brigade at the Majuba Hill, Commodore Richards mentions the conduct of Dr. Edward Mahon, R.N., as deserving of special approbation and reward.

HEPATIC ABSCESS AND DYSENTERY.

THE vexed question of the connexion between dysentery and tropical abscess of the liver was the subject of some discussion at the Pathological Society last Tuesday. The matter arose out of the presentation by Sir Joseph Fayrer of two examples of hepatic suppuration: one showing multiple abscesses apparently dependent upon dysentery; the other a large solitary abscess, in which it was doubtful if the intestinal affection, from which the patient had previously suffered, bore any relation to the liver disease. In his subsequent remarks Sir Joseph reaffirmed the opinion, which is held by him in common with most surgeons of Indian experience, that the solitary abscess is usually the outcome of a primary hepatitis, independent of dysentery, which may or may not be a concomitant of the case. This opinion, which was, it may be remembered, strongly advocated by the late Dr. Murchison, was supported at the meeting by Dr. Longhurst; but many of those who spoke took the contrary view. Thus, Dr. Dickinson exhibited a specimen of solitary abscess of the liver following extensive dysenteric ulceration contracted in this country after exposure to cold and an indigestible meal; and Drs. Wilks, S. West, and Moore adduced facts in the same direction. The subject certainly admits of more ample discussion, and it seems clear that both views are, to a certain extent, right. We believe that there is evidence of primary hepatitis even in cases of hepatic abscess arising in our climate under certain conditions, where there has been no trace of intestinal ulceration, and where everything pointed to primary inflammation, or where, in some cases, thrombosis with necrosis of the liver was the cause of the abscess. In other cases a single abscess may result from a local infective process from diseased intestines. Such cases, however, may be originally produced by the fusion of several "multiple" foci of secondary inflammation; but whether this be so or not they do not strictly come under the category of "tropical abscess," being linked ætiologically with those cases of disseminated suppuration of the liver which are admitted by all to follow upon ulceration of the intestines, as well as upon other sources of pyæmic infection; examples of which were quoted by Drs. Taylor, Moore, and Day, at the meeting. However, as we have indicated, the subject is certainly open to reconsideration, and it is one which the Society would do well to take up for special discussion, availing itself of the wide experience of such authorities as Sir Joseph Fayrer, for example, to initiate a debate which shall sift the matter to the bottom.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

THE extension of time accorded to intending exhibitors for making applications for space has been much appreciated. At the meeting of the committee, last week, it was found that the number of exhibitors amounted to nearly 400, and the frontage applied for to over 2000 feet. The applications from the Continent and from America have exceeded fifty. The success, therefore, of the undertaking is more than assured, and that it will prove a great source of attraction to visitors to the Congress there can be no doubt. The applications in all classes have been numerous, and from first-rate firms. The Commissioners of 1851, the Science and Art Department, and the Council of the Horticultural Society have vied with each other in their courteous endeavour to meet the wishes of the Exhibition Committee, and full justice will be enabled to be done to all exhibitors. A plan of the exhibition building is being made, and each exhibitor will have a portion of the plan sent to him with his exact position marked thereon, so that all confusion at the last will be avoided. The committee will, we understand, be glad to receive applications up to the time of the final allotment of space, which will be proceeded with on the completion of the plans. The claims of late applicants will, of course, be considered only after those who have already applied have been finally dealt with.

AN ACTION FOR DAMAGES AGAINST A SURGEON.

AN action for damages brought against Dr. Stainthorpe of Wareham on account of alleged careless and unskilful treatment of a fracture of a thigh was lately tried before the County Court judge at Wimborne, who gave judgment for the defendant. The issue was by no means a novel one, and the whole history of the affair and some of the medical evidence were as unsatisfactory as in many similar cases. The plaintiff recovered with a shortened but otherwise sound limb, and attempted to prove that the shortening was occasioned by improper treatment. In his support was brought the evidence of several local practitioners, one of whom declared that shortening was quite an exceptional occurrence after oblique fracture of the thigh. The most charitable view to take of such an opinion is that it is the result of inexperience. Professor Longmore considered the treatment adopted quite satisfactory, and stated, what is only too true, that in spite of all precautions shortening will very often eventually occur, even when none is present at first. Dr. Stainthorpe appears to have been very attentive and careful, and we sympathise with him under the extremely annoying circumstances in which he has been placed.

NON-LIABILITY OF PATIENTS FOR SERVICES RENDERED BY A SUBSTITUTE.

A COUNTY COURT Judge, according to *The Globe*, has lately ruled that when a medical man sends a professional brother to a patient instead of going himself, the patient may legally refuse to pay. Our contemporary thinks this important to doctors and a good ruling. We think it neither the one nor the other. It is not very important, because medical men as a rule, with few exceptions, do their own work, and do not trouble their neighbours to do it. The instances in which patients are handed over to a substitute are generally matters of arrangement, the patient's feelings being consulted as to the substitute whom he would prefer. Besides this, patients, as a rule, are incapable of such bad behaviour as is implied in accepting this ruling. They are such patients, we should say, as a doctor would be better without. A medical man cannot be ubiquitous, and most medical men occasionally require a holiday. To do the public justice, they feel this, and accept the fact with much generosity and good sense. For all these reasons the ruling is not very important to doctors, and we do not think it will be sustained by higher authorities. There are some special cases where doubtless it would be more reasonable, such as obstetric cases. Here a medical man should make a point, *if possible*, of attending personally. To send a substitute is a proceeding which can only be excused under exceptional circumstances. But even here exceptional circumstances will occur, and a patient is lucky in having a medical man who, failing himself, can always command a substitute.

A STEP IN THE RIGHT DIRECTION.

WE learn from a literary contemporary that a movement is on foot to petition the Senate of the University of London to abolish the habit of setting definite books for their pass examinations, substituting for that cram-fostering practice the selection of passages for translation with the aid of a dictionary. Such a change would be welcome on many grounds. The literature of schoolboys consists at the present time largely of so-called "keys" and translations, which are actually often committed to memory by the candidate. The University of London, whilst only an examining body, has done so much in the cause of education by indicating the lines on which it requires competent knowledge to be shown, that we may hope to see it lend a favourable hearing to these representations. The crying evil of the examination system is the encouragement it affords to the successful but baneful practice of "cramming," and any step which can tend to put a stop to this is decidedly "in the right direction."

BOGUS DEGREE REVELATIONS.

ANYTHING that Mr. John Buchanan—the principal personage in the bogus degree trade, and now in prison—may say is of little value; but the papers and documents which he is said to have handed over to the authorities of the United States are of a little more importance; these include letters from five thousand persons who either obtained, or wanted to obtain, degrees. This is bad enough, as showing the number of people in the world who are willing to perpetrate a fraud, and to pass off for what they are not. But more startling still is the revelation of the share taken in this disgraceful traffic by others—altogether, it is estimated that nearly ten thousand persons are more or less compromised by Buchanan's revelations.

WE regret to announce the death of Brigade Surgeon Exham L. Hiffernan, Army Medical Department, at the Royal Victoria Hospital, Netley, shortly after his arrival from Malta. Mr. Hiffernan entered the army as an Assistant-Surgeon on the 16th June, 1854, was promoted Surgeon in July, 1866, Surgeon-Major in June, 1864, and Brigade Surgeon in November, 1879. Mr. Hiffernan was for many years in the 19th Regiment, and served in the Crimean campaign, receiving the medal with clasps for Alma, Inkerman, and Sebastopol, and the Turkish war medal.

GEORGE EDWARD PAGET, M.D., F.R.S., Regius Professor of Physic, late President of the Council of Medical Education of the United Kingdom, has been elected to a Fellowship at Caius College, Cambridge. Dr. Paget was eighth wrangler in 1831, and in the following year was elected to a Fellowship, which he vacated by marriage, according to the then existing statutes of the College.

THE Court of Governors of Owens College have resolved that the Council should take steps to give evidence before the Royal Commission on Medical Legislation with the object of obtaining for the Victoria University power to confer medical degrees.

DR. W. MCEWEN has obtained the Lectureship in Surgery in the Glasgow Infirmary School of Medicine, recently vacated by Dr. Cameron. To the chair of Medical Jurisprudence the managers of the infirmary have appointed Dr. John Glaister.

IT is anticipated that University College, Liverpool, will open for its first session next October. The donations to the funds of the institution have reached nearly £100,000, and the preliminary work of drafting a constitution has just been completed.

MR. JOHN KELLOCK BARTON, Surgeon to the Adelaide Hospital, and Lecturer on Surgery in the Carmichael School of Medicine, Dublin, will be a candidate for the Vice-Presidency of the Royal College of Surgeons in Ireland, at the annual election in June.

THE *Daily Telegraph* draws attention to the statement made in the return of Sir E. H. Currie, to the effect that "during the last twenty-three days 1500 persons suffering from small-pox have been refused admission" to the small-pox hospitals of the metropolitan district.

OUR readers will have learned with regret that amongst the victims of the lamentable explosion on board the *Doterel* is the medical officer of the ship, Staff-Surgeon Septimus Evans, whose appointment dated from Dec. 13th, 1880.

THE Town Council of Oswestry has elected Mr. Lewis W. A. Aylmer, L.R.C.P., L.R.C.S. Edin., as Coroner for the borough, in the vacancy created by the death of Mr. J. Sides Davies, M.R.C.S.

THE office of deputy chairman of the Briton Life Association, long held by Dr. Samuel Richards, of Bedford-square, has been filled by the appointment of Dr. B. W. Richardson, LL.D., F.R.S.

VICTORIA HOSPITAL FOR CHILDREN.—The Princess Louise (Marchioness of Lorne), attended by Lady Sophia Macnamara and Captain Arthur Collins, paid an early and private visit to this hospital on the 28th ult., to inspect the out-patients' department, and subsequently visited the wards, speaking to each child in its cot, and leaving some toys for their amusement.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Walborough.—Estimated population, 1880, 7300; birth-rate 33·0 per 1000 inhabitants; death-rate 16·03 per 1000. Mr. Armstrong gives a curious and instructive instance of the exemption of the workhouse children, averaging 80 to 100 in number from infectious diseases, prevalent in the town: "Although the house is situated in the town, and scarlatina, measles, and whooping-cough have been frequently present among the children living in the adjoining street—the infection has never been carried over the workhouse walls. People sometimes allege, as an excuse for neglect and carelessness in carrying out sanitary precautions, that 'these complaints come in the air,' and that it makes no difference whether children are kept away from infected houses or not. The infective matter of these diseases is undoubtedly diffused in the atmosphere, but it is very doubtful if it ever travels even a very moderate distance, in the open air, without losing its infecting power. This instance, and others well known in regard to fever and small-pox hospitals, tend to show that active infection is not wafted for unlimited miles across the country, but is confined to the immediate precincts of the sick. These poor workhouse children are not particularly isolated, and the elder ones are frequently marched through the street; but they have a school and play-ground to themselves, have not many outside friends to visit them, and are consequently less liable to catch infectious disease than their richer neighbours. In a sanitary point of view workhouses and prisons are becoming the most healthy places of residence, and most free from epidemic disease." (Walborough forms part of the combination of which the other districts are Newton Abbot and Dawlish. The report as respects these districts has already been noticed in THE LANCET, pp. 672, 717.)

Hanley, Urban (*Staffordshire*).—Dr. Swift Walker reports for 1880 a birth-rate of 44·5 and a death-rate of 24·37 per 1000 of the estimated population, the former being 1 per 1000 more and the latter 1 per 1000 less than in the previous year. The most notable event of the year was a severe epidemic of what Dr. Walker designates choleraic diarrhœa, which prevailed during the months of July, August, September, and October, proving fatal to no less than 113 young children. Many of the cases, Dr. Walker observes, did not receive medical assistance until they were in a moribund condition, and of the outbreak generally he remarks:—"Every precaution was taken to warn the mothers, and many papers concerning the 'Proper Feeding of Infants,' published by Dr. Lankester, were distributed; but amongst the labouring classes the subject is very much neglected, as they *generally* attribute relaxation of the bowels to teething, and consider it rather salutary than otherwise—a great mistake, especially during such high temperatures as were experienced during the summer of last year. There is little doubt that a great number of the children succumbed to improper feeding and nursing, as food is in many cases given to a child whenever it is fretful. Few medical men can succeed in impressing upon mothers the vital importance of nursing or feeding children at *stated* intervals. Others succumbed to climateric influences, and some were in such a low state of vitality, either from hereditary predisposition or want of breast milk, that as soon as they were attacked with the disease there was not sufficient constitutional stamina to withstand any serious shock as such an exhausting disease as diarrhœa. In the case of many children of the poorer classes met with in practice, the bowels and stomach are in a state of sub-acute congestion from improper feeding long before any active disease makes its appearance. Then diarrhœa or any other affection makes a secondary complication to deal with, and must inevitably lead to a fatal result." The report is chiefly founded on the data as to the mortality of the locality, and does not give much information as to the sanitary condition and administration of the place.

Buckingham, Rural (*Bucks*).—Mr. De'Ath reports a death-rate of 14 per 1000 of the population in 1880, the lowest death-rate recorded in the district for several years. He writes of the sanitary condition of the district having been much improved in recent years, and states that it was free from any serious epidemic disease in the past year. Evidently the question of cottage accommodation is one of the most serious questions in this district.

Bollington, Urban (*Cheshire*).—Mr. James Allen reports approximately for this district in 1880, and pending the results of the census, a birth-rate of 33·8, and a death-rate of 23·73 per 1000 living. He remarks upon the excessive infantile mortality in the district as contrasted with the previous year, and to the registered causes of death—namely, convulsions, diarrhœa, debility, atrophy, marasmus, or the like, causes which, he observes, "experience teaches us are frequently produced by improper food which children get."

Dundee.—Dr. Wallace reports a manifest and generally satisfactory improvement in the state of the public health of this town during the four weeks ending Feb. 26th. The rate of the mortality for this period fell to 19·9 per 1000 inhabitants as contrasted with 27·9 for the corresponding period of the previous year. Typhus still continues in the town, 13 cases having been reported during the four weeks in question. Dr. Wallace attributes much of this persistence to the real nature of the disease not having been at first suspected, and consequently not early enough reported.

Wortley, Rural (*Yorkshire*).—Dr. Samuel Drew reports for this district in 1880 a death-rate of 18·0 per 1000 inhabitants, as compared with 23·0 per 1000 in 1879, and he states that the sanitary condition of the whole district is improved; but although several of the villages in it are well supplied with water, others, it appears, are not, and need the attention of the sanitary authority in this respect.

Kirkham, Urban (*Lancashire*).—Mr. Davidson Walker reports for the year 1880, among a population estimated at 4043, a birth-rate of 37·5, and a death-rate of 19·5, per 1000 inhabitants. The year was characterised by a great decline in the infant mortality of the district, which Mr. Walker assigns to the efforts made by the sanitary authority to promote the health of the community. It would appear, however, that there are still matters which remain for the sanitary authority to do before the town can have reaped all the results to be obtained from a thorough sanitary administration, and we shall hope to learn from future reports of their medical officer of health that they have been done.

Glasgow.—The remarks made by Dr. Russell to accompany the mortality tables of the City of Glasgow for the quarter ending the 31st Dec. 1880, are of the usual detailed character, and cannot usefully be either epitomised or detached from the tables to which they apply. The death-rate of Glasgow in the fourth quarter of 1880 was 24·0 per 1000 inhabitants, as compared with an average of 27·6 for the corresponding quarter of the ten preceding years.

Cases illustrative of the present difficulty of dealing with small-pox in the metropolis appear to be multiplying in the police-courts. A woman was recently fined in one court for suffering her child, a boy, to play with other children in the streets before he had fully recovered from small-pox; and a laundress was fined in another court for continuing her business while she had a son ill from small-pox in the house where it was conducted, and so conveying the disease to the servant of a customer through linen submitted to wash. In this case the illness proved fatal, and no medical man was called in. In a third case a householder was fined for sending a servant home in a public tramcar with the eruption of small-pox out upon her.

A very useful Parliamentary return has been issued, under the signature of Sir John Lambert, K.C.B., of the Local Government Board, of the present number and names of the Urban Sanitary Authorities in England and Wales, under the Public Health Act, 1875, the names of the several parishes and townships within the district of each such authority, distinguishing those parishes and townships which are wholly from those which are partly within the district, and also the area, the population, according to the census of 1871, and the gross estimated rental and rateable value of each district.

The discussion on Dr. Richardson's Address, at the Sanitary Institute, on the management of small-pox cases in the metropolis and large towns is still further adjourned to May 11th, when it is expected that Dr. Richardson will make his reply to the various observations which have been made.

Two groups of houses, one consisting of twenty and the other of twenty-three, were recently directed by the magistrate sitting at Worship-street to be closed until they could be placed in habitable repair.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a further slight decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5730 births and 3089 deaths were registered last week. The births exceeded by so many as 544, whereas the deaths were 168 below, the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had been equal to 22·9 and 22·0 per 1000 in the two preceding weeks, further declined last week to 21·2. The lowest rates in the twenty towns last week were 12·8 in Leicester, 15·7 in Norwich, 15·8 in Sunderland, and 16·8 in Leeds. The rates in the other towns ranged upwards to 23·5 in Manchester, 23·8 in Wolverhampton, 25·1 in Liverpool, and 26·9 in Salford. During the first four weeks of the current quarter the death-rate in the twenty towns averaged 22·1 per 1000, against 24·8, the average rate in the corresponding periods of the five years 1876-80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 410 and 382 in the two preceding weeks, further declined to 375 last week; these included 83 from measles, 83 from whooping-cough, 71 from small-pox, 60 from scarlet fever, and 35 from fever, principally enteric. The annual death-rate from the principal zymotic diseases averaged 2·6 per 1000 in the twenty towns, and ranged from 0·9 and 1·2 in Sunderland and Norwich, to 3·2 and 3·4 in London and Liverpool. Measles showed the largest proportional fatality in Bristol, Newcastle-upon-Tyne, and London. The fatality of whooping-cough was very considerably below the average for the season; and the deaths from scarlet fever were also below the average. The highest death-rate from fever was recorded in Liverpool. The 11 deaths from diphtheria in the twenty towns included 6 in London and 2 in Liverpool. Small-pox caused 75 deaths in London and in its outer ring of suburban districts, and 1 in Birmingham; whereas no fatal case was recorded in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased from 820 to 963 in the four preceding weeks, declined to 943 on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 395 and 338 in the two preceding weeks, further declined last week to 328, and were 11 below the corrected average number in the corresponding week of the last ten years; they included 191 from bronchitis and 99 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 4·6 per 1000 in London last week. The rate from the same diseases was equal to 6·0 in Liverpool, and to 8·0 in Salford.

The causes of 67, or 2·2 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·2 per cent. in London, whereas it averaged 3·1 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth, Plymouth, Birmingham, Bradford, Sunderland, or Newcastle-upon-Tyne; while the proportions of such deaths were largest in Norwich, Salford, and Leeds.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half persons, the annual death-rate last week was equal to 21·2 per 1000, against 23·5 and 22·1 in the two preceding weeks; this rate corresponded with the average rate in the twenty English towns. The rates in the eight Scotch towns ranged from 19·3 and 20·0 in Aberdeen and Edinburgh, to 23·4 and 25·4 in Leith and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 82 and 69 in the two preceding weeks, further declined to 64 last week; they included 21 from whooping-cough, 15 from diarrhœa, 9 from diphtheria, 7 from fever, 6 from measles, 5 from scarlet fever, and one from small-pox. The annual death-rate from these zymotic diseases averaged 2·5 per 1000 in the eight towns, which was slightly below the average rate (2·6) from the same diseases in the twenty English towns. This zymotic death-rate in the eight Scotch towns ranged from 1·1 and 1·3 in Paisley and Greenock to

2·9 in Edinburgh and Dundee, and 4·3 in Leith. The fatal cases of whooping-cough, which had been 26 and 24 in the two preceding weeks, further declined to 21 last week, of which 9 occurred in Glasgow, 4 in Edinburgh, and 3 in Leith. The 15 deaths from diarrhœa showed an increase upon those returned in the previous week, and included 5 in Dundee, 4 in Edinburgh, and 3 in Glasgow. The 9 deaths from diphtheria, of which 5 occurred in Glasgow and 2 in Dundee, showed an increase upon those in the previous week. The deaths referred to "fever" (typhus, enteric or typhoid, and simple continued), which had been 7 and 11 in the two previous weeks, declined again to 7 last week, of which 5 were returned in Glasgow, and 1 each in Edinburgh and Perth; the annual death-rate from this cause was equal to 0·28 per 1000, and slightly exceeded the average rate from the same cause during last week in the twenty English towns. The fatal cases of measles and scarlet fever showed a considerable decline from recent weekly numbers. The death from small-pox (the first that has occurred in any of these eight towns since January, when one was registered in Dundee) was returned in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 163, 144, and 135 in the three preceding weeks, further declined to 116 last week, and were equal to an annual rate of 4·6 per 1000, against 4·2 from the same diseases in London. The greatest proportional fatality from lung diseases in the Scotch towns occurred last week in Aberdeen and Paisley.

HEALTH OF DUBLIN.

The rate of mortality was not quite so high in Dublin last week. The annual death-rate in the city, which had been equal to 29·0 and 32·6 per 1000 in the two preceding weeks, declined again to 30·7 last week. During the first four weeks of the current quarter the death-rate in the city averaged 30·8 per 1000, against 22·2 in London and 21·2 in Edinburgh. The 196 deaths in Dublin last week showed a decline of 12 from the number in the previous week; they included 19, or not quite 10 per cent., which were referred to the principal zymotic diseases, against only 12 and 9 in the two previous weeks. These 19 deaths from zymotic diseases included 14 from fever (typhus, enteric or typhoid, and simple continued), 3 from diarrhœa, 1 from scarlet fever, 1 from whooping-cough, and not 1 either from small-pox, measles, or diphtheria. The annual death-rate from these zymotic diseases was equal to 3·0 per 1000 in Dublin last week; the rate from the same diseases was equal to 3·2 in London and 2·9 in Edinburgh. The deaths referred to fever in Dublin, which had been but 8, 7, and 2 in the three previous weeks, rose to 14 last week, and exceeded any weekly number since the end of February; the annual death-rate from this cause in Dublin last week was equal to 2·19 per 1000, and was more than nine times the average rate from the same cause prevailing in the twenty English towns. The deaths referred to diarrhœa showed a slight increase, while the fatal cases of the other principal zymotic diseases were again exceptionally few. The deaths of infants and of elderly persons differed but slightly from those returned in recent weeks.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

Messrs. Edwards and Son, of Great Marlborough-street, announce they have constructed a fire-grate founded upon Dr. Arnold's principle, for which they claim a practical immunity from smoke, a long-continued fire without need for interference, and the doing away of chimney-sweeping except at intervals, perhaps, of ten years. Mr. R. H. Griffin, moreover, of Lonsdale-chambers, Chancery-lane, has introduced a fire-grate combining the merits of the closed hot-air stove and the ordinary register stove, with the additional professed advantage of giving off a minimum of smoke.

The National Health Society have made arrangements for a series of lectures to be delivered to working plumbers, at the Rooms of the Society of Arts, on "The Science and Art of Sanitary Plumbing." The lecturer will be Mr. S. Stevens Hellyer, and the lectures will be delivered on the evenings of May 17th, June 1st, 14th, and 28th, and on July 12th and 28th.

A considerable amount of fever—typhus and enteric—exists at present in the Union of Waterford, and additional accommodation for patients in the Fever Hospital is urgently required.

THE SERVICES.

Surgeon-Majors G. C. Gribbon, H. B. White, and Surgeon C. C. H. Smyth are on passage home from India in H.M. troopship *Malabar*, which left Bombay on April 12th.

Deputy Surgeon-General C. D. Madden has been ordered to Aldershot for duty, vice Deputy Surgeon-General J. Ogilvy, transferred to Bermuda.

ADMIRALTY.—Staff-Surgeon Stephen Sweetman has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of April 1st, 1881. Fleet Surgeon Stephen Sweetman has been appointed to the *Invincible*, vice Endey.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, April 28th, petitions were presented as follows:—From Clogheen Union for inquiry into the subject of butter adulteration; from Hampstead against a loan to the Metropolitan Asylums Board in connexion with the proceedings in the small-pox hospital case; from a large number of provincial towns against the opium trade; and from various places against the Rivers Conservancy Bill. Mr. Mellor gave notice that he will move the rejection of the Poor Removal (Ireland) Bill. Sir Sydney Waterlow gave notice that in Committee on the Alkali Works Bill he will move the following amendment:—"It shall be necessary to prove to the satisfaction of the judge before whom any action for fines under this Act is or may be tried, that injury has been caused to the health of the inhabitants of the district from or in consequence of the management of any such work, and from the emission of gases therefrom, or that damage has accrued to some person or persons, to an extent of not less than ten pounds."

Fulham Small-pox Hospital.

On Friday Colonel Makins asked the President of the Local Government Board whether it was a fact that the authorities of the Fulham Small-pox Hospital, or the parish authorities, were erecting a temporary wooden building for the reception of small-pox patients on the surface and extending to the whole width of the Imperial-road leading to the river Thames from the Fulham-road; and, if so, by what authority such an erection was placed upon a highway dedicated to the use of the public. In putting the question, the hon. member said he believed the erection was really a tent surrounded by a wooden hoarding, and that the authorities were the Local District Board. There were nine patients in the tent, and he believed there was great local excitement, and some talk of an attempt to pull it down. Mr. Dodson said the Local Government Board had no information as to the erection of any such building. The only authorities over whom the Board had jurisdiction who had power to provide hospital accommodation in Fulham were the managers of the metropolitan district and the guardians. From neither of these bodies had the Board received information of their intention to adopt the extraordinary proceeding of setting up a small-pox hospital on a public highway. Subsequently Col. Makins asked the Home Secretary whether he would make inquiry into the matter, and Sir W. Harcourt at once agreed to order an inquiry to be made.

On Monday a petition from various Scotch burghs was presented in favour of the Lunacy Law Amendment Bill. The following notice was given for Thursday:—Mr. John Hollond to ask the Secretary of State for the Home Department whether any action has been taken by the local authorities under "The Artisans' and Labourers' Dwellings Act (1868) Amendment Act, 1879;" and, if so, whether any account of the funds spent in carrying out the Act has been presented by the local authorities in accordance with section 18. And whether any application has been made to the Home Office under section 38 of "The Sanitary Act, 1866."

On Tuesday, the Select Committee on the Coroners (Ireland) Bill was nominated as follows:—The Attorney-General for Ireland, Mr. Daly, Mr. Ewart, Mr. Healy, Mr. R. Fowler, Mr. Litton, Mr. Richardson, and Mr. Tottenham. The Committee were instructed to consider the operation of the law relating to coroners in Ireland, and if they think fit to amend the Bill accordingly. Mr. Healy moved that the Committee have power to send for persons, papers, and records, but the Attorney-General for Ireland opposed this as unnecessary, and on a division it was rejected by 75 to 15. Mr. Summers asked the Vice-President of the Council whether the Royal Commission which is being appointed to inquire into the working of the Medical Acts will be empowered to receive evidence as to the grounds upon which the Victoria University claims to have the right conferred upon it of granting degrees in medicine. Colonel Makins asked the Secretary of State for the Home Department if he will give to the House the result of his inquiries on the subject of the small-pox tents in the Imperial-road, Fulham.

Mr. P. A. Taylor put down his anti-vaccination resolution for Tuesday, May 31st.

On Wednesday Mr. Blennerhassett was added to the Select Committee on the Coroners (Ireland) Bill. Colonel Makins deferred to Friday his question as to the Fulham Small-pox Hospital; and for the same day the following notice was given: Mr. Donaldson-Hudson, to ask the Secretary of State for War, whether Her Majesty's Government will accord to Volunteer Battalion Surgeons, after twelve years' service, the rank and title of Surgeon Major, as in the case of Militia Battalion Surgeons; and whether they will give to them, under the Memorandum showing the principal changes in army organisation, &c., intended to take effect from 1st July, 1881, the same privileges upon retirement, after fifteen years' service, as to other officers of the Auxiliary Forces.

Maintenance of Lunatics.

Mr. Stanley Leighton gave notice that on an early day he would call attention to the state of the law relating to the superintendence and maintenance of lunatics, and move that it is unfair to the ratepayers to oblige them to maintain out of the poor rates asylums which are largely occupied by the middle and professional classes; that the practice of granting licences to individuals which authorise them to make a profit by keeping private asylums is liable to abuse; and that it is the duty of the Government to undertake the charge of all lunatics.

The Contagious Diseases Act.

On Thursday Mr. Hopwood asked the Secretary of State for War whether his attention had been called to the case of a friendless girl named Elizabeth Burley, who recently, through fear of the police officer appointed to carry out the Contagious Diseases Act at Dover, threw herself into the water of the harbour. Sir W. Harcourt said he understood that the girl in question had been under the observation of the police for the past three weeks in consequence of leading an immoral life. That fact she admitted at the Sailors' Home. It was therefore the duty of the police to ascertain her name and address, with a view to cautioning her under the statute. In doing that the police seemed to have shown a want of discretion and judgment, for which they would be severely reprimanded. The girl threw herself into the water, but was promptly rescued. He believed there was now reason to hope that the girl would be reclaimed from the unhappy life she led.

Oleomargarine.

Mr. Severne asked the President of the Board of Trade whether oleomargarine is permitted to be sold under the name of butter; and, if not, whether since the admixture of oleomargarine with butter may be easily detected by analysis, the district inspectors are directed to endeavour to discover such fraudulent admixture. Mr. Dodson said the sale of oleomargarine as butter was not permitted under the Sale of Food and Drugs Act, and numerous prosecutions were taking place where it had been sold as such.

Small-pox in the Metropolis.

Baron Henry de Worms asked the Secretary to the Local Government Board whether, seeing that the small-pox epidemic is very much on the increase in Greenwich and other parts of the metropolis, and that the hospitals of the Asylums Board are overcrowded and incapable of dealing with the emergency, any and what steps will be taken by the Local Government Board to secure extra accommodation for small-pox patients whose confinement in crowded dwellings must tend greatly to increase the spread of the epidemic. Mr. Dodson said the Local Government Board had been pressing upon the guardians and vestries and district boards the necessity of supplementing the accommodation for small-pox patients which was at the disposal of the Asylums Board, and he was happy to say that in several cases effect had been given to the Board's representation. At the same time he was quite sensible of the urgent necessity for further accommodation and isolation for such cases, and the Board were earnestly endeavouring to get it provided. Mr. Dawson.—In connexion with this subject may I ask the right honourable gentlemen if the Local Government Board have taken any steps to provide hospitals or homes for patients during the period of convalescence, which we know is most dangerous with regard to the spread of the disease? Mr. Dodson.—No, sir; there are no convalescent homes. Mr. Dawson.—On another occasion I shall ask what are the intentions of the right honourable gentlemen with regard to the promotion of the convalescent hospitals.

DR. BENJ. W. RICHARDSON ON MEDICAL CORONERS.

THE CORONERSHIP OF CENTRAL MIDDLESEX.

IN the course of his remarks as chairman of a meeting of freeholders, convened to promote the election of Dr. Danford Thomas, Dr. B. W. Richardson spoke as follows:—

We doctors, when we give evidence at an inquest, feel altogether different, as far as our feeling is concerned, according to the coroner we go before. When I was a young man I lectured on Medical Jurisprudence, and, my lectures being popular, I was often asked to conduct post-mortem examinations, and to prepare or give evidence before the coroner. For seven or eight years I had much practice of this kind in London. There was at that time one of the most remarkable men in London as Coroner for this district—Mr. Wakley—a man of intense earnestness, force of character, indomitable courage, and sound freedom of expression in the views which he took. He was a medical coroner. And I remember well how very different a matter it was to give evidence before Mr. Wakley compared with giving it before a coroner who knew nothing about medicine. It was simply impossible to make a mistake before Mr. Wakley, for there he was ever ready to test the truth down to the bottom. If it came to a question of chemistry, anatomy, or pathology, Mr. Wakley was ready; woe be to him who made a mistake even in use of terms: and the result was that never have the public interests been so well served as from the time when Mr. Wakley, as a coroner, took them in hand. It is natural that a witness, giving evidence on technical points, should feel more anxiety, and be more exact, if he goes before a man who is himself a competent judge of the matter, than if he goes before a man who has no knowledge of the subject beyond the rest of the community. The freeholders of this district of the county of Middlesex will, I am sure, easily follow these plain arguments, and upon common-sense grounds come to the conclusion that in the case of a sudden, it may be a mysterious, death, the person who has the best knowledge of the causes of death is the medical man. On the opposition side what is there to be said? You will remember that in 299 out of every 300 inquests the cause of death is the subject for consideration—purely, solely. Then comes one case when some technical legal knowledge may be required. If now the worst comes to the worst, you would want 299 times of the doctor to one of the lawyer. But the worst does not come to the worst on each occasion, for the doctor need not stand out exceptionally bad, even in law. If you turn to medical men you must not consider they are ignorant of the law of evidence. Why, the whole training of a physician or surgeon is calculated to make him most competent to understand the laws of evidence. We doctors examine persons who have come before us both subjectively and objectively. We take, that is to say, what they tell us, and we look for ourselves. Does the solicitor have a better chance of learning the law of evidence than the doctor? I have never known a solicitor who, when it came to be a question of evidence, did not say, "We must consult counsel," did you? It is not so with a medical man. He knows what it is to examine into all facts that come before him, and hence, on these grounds of capability and training, the verdict may well be in favour of the medical practitioner. The coroner, it is said, is a magistrate. Well, I undertake to say there are more doctors magistrates in this country than there are lawyers, and that on the magisterial bench they know what evidence to accept and what to reject more acutely than most other men, because of their education. In respect to the legal duties of the coroner's office, they are simple, they are limited, they are fixed. They are all practically contained in one book, which a doctor as well as a lawyer can master in three months easily, and which the lawyer equally with the doctor would have to master. But a study of years would not give the lawyer the knowledge of the doctor for discovering the one great fact in 299 cases out of 300—the cause of death. I hope now I have put the question as my friend the "freeholder" wished, fairly and plainly forward. We need not dispute about particular men until we get to true principles. Bear that fully in mind, and all is safe. In this case the principle is that a skilled medical man is necessary for recording causes of death, and that point settled, we come to the man himself. It remains for me to ask the freeholders whether they have made up their minds as to whether the medical coroner is the best man, and the man that suits them. I will say nothing against legal opponents, they are men I should have great pleasure in consulting on legal matters. I should not consult them as to the cause of death. I would consult them with every respect on the making of a will, or the drawing of a lease. Have you a medical man to support and sustain the line of coroners,—the line of Wakley, Lankester, and Hardwicke,—before you? I say you have. You have before you all that you want in Dr. Danford Thomas, who has actually supplemented his claims by the claim of being a member of the Inner Temple, where he has for some time studied law. Dr. Thomas has been for some years the deputy of the late Dr. Hardwicke; he has held 1800 inquests; he is a thoroughly well-informed man; he has received a sound, scientific, medical education. We know that he is a man who has learnt the duties specially appertaining to this office of coroner; we know that he is assiduous in his work, he has shown skill in the execution of it, and that he is doubly trained for it.

Correspondence.

"TWO SETS OF CONVICTIONS."

To the Editor of THE LANCET.

SIR,—If the orthodox practitioners of medicine had settled convictions on some theory of the treatment of disease, such as some of the "pure and simple" followers of Hahnemann profess to have—if one school of practitioners were uniformly to treat disease on the principle, say of *contraria contrariis curantur*, and another on the principle of *similia similibus*—there would then be no obstacle in the way of appreciating the value of your editorial remarks in this day's LANCET on professional ethics. Seeing, however, that the orthodox practitioner of medicine has no such settled conviction, and that in his treatment of disease he often uses remedies in a way that certainly cannot be explained by the rule of contraries—e.g., the use of small doses of ipecacuanha in the treatment of vomiting (Ringer), of small doses of Dover's powder or of picrotoxin in morbid sweating (Murrell), of small doses of arsenic in gastro-enteric inflammation (Ringer), &c.; and seeing, moreover, that there are now very few homœopaths who adhere scrupulously to the so-called law of *similia similibus* to the neglect of arts learnt by experience—seeing all this, the edge of your remarks is blunted.

Your strictures would have been sharp-edged enough forty or fifty years ago, when the dividing line between orthodox medicine and homœopathy was clear and plain; but now when not even Sir W. Gull himself has, I suppose, any settled conviction on the theory of the treatment of disease, would it not be better, because more in harmony with the present condition of parties in medicine, to try to open one's eyes to view the large common ground that there is for the homœopathist and the ordinary practitioner of medicine?

I am, Sir, yours truly,

Scarborough, April 30th, 1881. F. FLINT, M.D.

*** Our correspondent has wholly misread the article to which he refers if he does not understand that we equally denounce *similia similibus curantur* and *contraria contrariis curantur*. They are both mere superficial statements of mere surface appearances. The causes of the effects produced underlie these alleged *methods* of action; and scientific inquiry at once reveals the fallacy of the deductions drawn from insufficient and misunderstood data. Neither ipecacuanha, Dover's powder, nor picrotoxin acts homœopathically or allopathically; the action is in each case strictly in accordance with the known laws of therapy. Dr. Flint as a "homœopathist" naturally takes a one-sided view. We are against *all* one-sided views. If there were such a system as "allopathy"—which there is not, and never was,—we should condemn it as we do "homœopathy." Scientific medicine is rational medicine, and knows nothing of systems.—ED. L.

To the Editor of THE LANCET.

SIR,—Is it not a very significant circumstance that when the leading so-called "homœopath" of London seeks a consultant whose opinion is considered worth anything he cannot find one in the homœopathic ranks? And this for the simple and sufficient reason that not one physician or surgeon in the front rank of the profession is to be found among the homœopaths.

Sir W. Jenner deserves the thanks of the whole profession for the manly way in which he has acted in this matter; and I make bold to say he has the whole provincial profession, at any rate, with him.

I am, Sir, your obedient servant,

Hanley, Staffordshire, April 16th, 1881. W. D. SPANTON.

To the Editor of THE LANCET.

SIR,—Will you grant me space for a few words on the now once more prominent question of consulting with homœopaths, a question which all who look upon our profession as a trust rather than a trade must deem of important moment. It seems imperative that no uncertain voice should be heard on this matter, and that the profession should be able to give a good reason to itself and to the public for the line of conduct which it intends to pursue.

Some explanation to the public, I think, is still needed on this question, lest the good custom approved by our College of Physicians of refusing to consult with homœopaths be misunderstood, or regarded as the outcome of mere class punctiliousness, or of narrow professional etiquette. Why do most of us refuse to meet the homœopaths? That a doctor of the so-called "orthodox" school cannot meet a homœopath in consultation is surely not only because they differ in the matter of *treatment*. On any one given case it is possible that two "orthodox" practitioners might differ in treatment almost as widely as both of them would from a homœopath. But scientific and honest students of medicine as represented, we would hope, by the Fellows of our College, believe that the plausible and flimsy system called homœopathy, like all other "systems" of treatment, is delusive, and that a "consultation" with a believer therein is a contradiction in terms, a moral and scientific solecism. Such a consultation is not a question of advisability; it is impossible; there is no common standpoint. Hence I would submit, with all deference to the distinguished men who have approved of Dr. Quain's action in the instance of Lord Beaconsfield's illness, that Dr. Quain's plea that the practitioner in attendance was not treating his patient homœopathically does not touch the real point at issue. There may be no reason why any physician should not have seen Lord Beaconsfield, *or any other person*, and treated him independently, whether the homœopathic doctor was nominally dismissed or not; but on the permissibility of any such "consultations" as have lately been reported in the daily papers I feel, in common, I think, with the vast majority of the Fellows of that College of Physicians whose chief and most admirable function perhaps is to keep up that high standard of professional truth and honour, which, as so ably contended yesterday by our late president, is its proper boast, that Sir William Jenner acted in the only right manner when he refused to consult with Dr. Kidd as a professional colleague. Doubtless, Sir William Jenner must have felt deeply the gravity of his decision in this case, but did he not speak almost the last word in this controversy, when in his trenchant and pregnant remarks on the subject he said that if Dr. Quain's conduct met with the approval of the College, his own action deserved its censure? As a member of a profession which ought to be more respected than it is, and as a Fellow, though a very junior one, of a College which is laudably jealous of its high position, I would add my small tribute of gratitude to the President of that College for his fearless action and outspoken expressions on this undeniably important question.

I am, Sir, yours faithfully,

Upper Berkeley-street, W., April 12th, 1881. H. DONKIN.

THE OLD UNIVERSITIES AND THEIR MEDICAL DEGREES.

To the Editor of THE LANCET.

SIR,—By the courtesy of the author I have been favoured with a copy of the able and eloquent address delivered by Dr. Morgan last February at Owens College. The interest in the subject and its importance are shown by your leader of April 9th, and I therefore, with your permission, shall be glad to make a few observations upon it.

In the first place, let me say how heartily I sympathise with Dr. Morgan in his grievance that the Victoria University should be debarred the power of conferring medical degrees. With a governing body and a professoriate, including among its members some of the most eminent men in the country, the new university was not likely to enter into a degrading competition with other licensing bodies for the sale of its diplomas; the strong opposition of those who feared such a result could have no real ground for existence, and when the authorities maintained that the degree would be given only when there had been both a sound training in arts and a very high standard of professional attainment, some other motive for the opposition must have been at work, which, if, as has been hinted, it was simple jealousy, was unworthy of the members of a liberal profession. I cordially hope this defect in the charter will soon be remedied, and whilst the General Medical Council is spending its golden moments in interminable discussions on medical education, and whilst conjoint schemes are being alternately resuscitated and submerged, the Lancashire University may show some practical result and legitimately compete with other institutions in the training and production of those who are not only skilful doctors, but also educated gentlemen.

When, however, Dr. Morgan says "that by the older universities medical education has been utterly and wantonly neglected" (page 8), and speaks of the "grievous wrong that has been inflicted by the neglect" (page 9), he ignores altogether what has been done in Cambridge in late years, and the language is stronger than the occasion justifies. It will gratify many, I know, and surprise more, to learn that at the present time upwards of one hundred students are prosecuting their medical studies at Cambridge, and that last year in June and in December 131 students passed the various examinations for the M.B. degree. The following are the numbers, which can easily be verified by reference to the Cambridge University Reporter.

		Passed in June.	Passed in December.	Total.
1st Examination for M.B.		33	29	62
2nd " "		15	17	32
3rd " "	Part I.	13	14	27
" " "	Part II.	15	11	26
		76	71	147
Deduct names appearing in two lists				16
				131

These numbers are yearly increasing, since the facilities and opportunities for medical study here, in the lecture-rooms, the laboratories, and in the wards of the hospital, have become more generally known and appreciated; new professorships are about to be founded, and I hope at no very distant period others will follow. With these facts and statements, therefore, it is clear that the charge of "neglect of medicine" dependent upon the "whole genius and arrangements" of this University must fall to the ground.

But the facilities for professional study are not the only inducements which Oxford and Cambridge offer to intending medical students. By the arrangements of the place these students are subjected to the same discipline, meet in the same dining-hall, are reared in fellowship and communion with men of various tastes and pursuits, and destined for very different vocations and occupations, and so interests are created and friendships formed which, for good or evil, have a far-reaching effect upon their lives; the view so well expressed fifty years ago by my distinguished namesake still holds good:—"In England there always have been among physicians those who have been upon an equality of education with the noblest and most learned in the land. They have been mixed with them at our public schools and universities; they have contended with them in honourable rivalry, and their minds have taken a congenial character from the similar studies of their youth. At length they have all separated to their several destinies for life: some to the Senate, some to the Bar, some to the Church, some to Physic. These men so educated, have ever afterwards looked with esteem upon each other and each other's pursuits. And thus have the most illustrious men of every age, who could know nothing of physic as a profession, viewing it through those whom they have known engaged in it, been compelled to regard it with reverence and honour. In this way a credit has been derived to our common profession, in which every individual in every rank of it has partaken, when those whose good opinion is most coveted have taken their estimate of physic and physicians from contemplating the characters of such men as" (and here let me insert living examples), Dr. George Paget, Dr. George Budd, Sir James Alderson, Sir George Burrows, and Sir Thomas Watson. And as I write down these honoured names, all of which appeared high in the list of Cambridge wranglers, I cannot help regretting that, with two or three brilliant exceptions, so small a number of the medical students at Cambridge of the present day submit themselves to the same logical training which in the examples cited has been attended with such marked success. Inconsiderately, I think, to use no stronger term, and to the disadvantage of many, they are urged at once to turn their attention to professional or scientific subjects, forgetful that the mind must undergo a long training before it is fit to grapple with science, and that time spent in the development of the logical faculty is time saved. In the last Hunterian Oration Mr. Holden, after an experience as a teacher of forty years, speaking on this subject, says, "In students who have had a public school training, I have found a fuller development of the logical faculty, a more cultivated memory, a greater grasp and power of combination. I have found the task of teaching them so much easier, that I have no hesitation in saying that I can teach such pupils more in two months than others who have not had a like education in six." These are words which scientific or "modern" educators would do well to weigh.

Still, the training here is successful, and judged by the number of hospital appointments in London held by her graduates, Cambridge has no reason to complain of any lack of appreciation. May I, in conclusion, venture to hope that when the Victoria University has obtained its rightful and proper powers, the rivalry that may be developed in medical matters between the universities shall be hearty and vigorous, and shall, whilst upholding the dignity of the profession, promote the advancement of medicine and the general welfare of mankind. I am, Sir, yours truly,

Cambridge, April 27th, 1881. P. W. LATHAM.

MEDICAL ETHICS.—SHOULD THE PROFESSION CO-OPERATE WITH HOMŒOPATHS WHO ARE MEDICAL OFFICERS OF HEALTH?

To the Editor of THE LANCET.

SIR,—I have pleasure in sending you a report of Dr. Ballard's opinions on the recent epidemic of scarlatina in Halifax, and desire particularly to draw your attention to one paragraph in the published account of his observations to the Halifax Town Council. Dr. Ballard is reported to have said: "The medical officer complained that some of the medical men would not send reports of new cases to him. He (Dr. Ballard) thought that, whatever professional opposition there might be, the medical men ought on these occasions, and for the good of the town, to put their feelings in their pockets." When Dr. Ballard speaks on sanitary matters few would feel disposed to challenge his views. When he pronounces judgment on a matter of medical ethics his dicta have not the same weight, so that I have no hesitation in asserting that his views are erroneous, and not in harmony with those of the majority of the profession. In a grave national emergency of recent date THE LANCET was the mouthpiece of medical principles, and laid down the ethical rules which should guide the profession in their dealings with those who professed or practised homœopathy. Sir William Jenner has been, as you so well put it, in strictest accord with the great body of the profession. The College of Physicians of London, by the election of Sir William Jenner as President, have confirmed your verdict. There cannot be two moralities—one for London and one for the provinces. You are familiar with the state of professional feeling here, caused by the selection by the Town Council of a practitioner of homœopathy. In a memorial, signed by thirty-four qualified medical men, presented to the Town Council at the time of the appointment, the following paragraph occurs:—"Concerned as we are with the prevention and cure of disease, we hoped for the appointment of some fully qualified practitioner, who would command the respect, support, and co-operation of his *confrères*, which we believe to be essential for the effective performance of his duties, and for the production of any real improvement in the sanitary state of the district. But the candidate of your choice, by his advertised connexion and association in practice with a homœopathic chemist, and by the adoption of views and principles repudiated by the great body of the profession, has cut himself off from the possibility of such co-operation."

The Town Council paid no heed to our opinions; forewarned, they must accept the consequences. Yet Dr. Ballard thinks that we should co-operate with a man of the stamp who is now medical officer of health for this important town. This ethical question has a wider range, so that it is desirable to have the opinion of professional leaders as to the justice of our action. It affects the practitioners of Hastings and St. Leonards. Time has not toned down the differences in Halifax. It has not increased our estimation of our medical officer of health, and he has cut himself off deliberately from all professional intercourse.

I took a leading part in instituting the inquiry by Dr. Ballard, and I am willing to take the fullest share of any censure that may be passed for my want of co-operation. Dr. Ballard's opinion will not alter my course of action. As for the other members of the profession, I leave them to speak for themselves. I think there cannot be two opinions as to the true course of action under conditions where a homœopath is forced upon the profession.

Yours faithfully,

Halifax, April 20th, 1881. T. M. DOLAN, L.R.C.S. ED.

GLASGOW.

(*From our own Correspondent.*)

A TOLERABLY well attended public meeting of those favourable to the establishment of a hospital on the south side of the city was held a few days ago; the Hon. the Lord Provost was in the chair. Many of the large employers of labour in the southern districts were present, while the landed and other interests were well represented. It was unanimously resolved that, having regard to the insufficiency of accommodation in the existing infirmaries and to the great distance of these institutions from the southern districts, a public hospital of the kind desired should be erected in a suitable situation, and an influential committee was appointed to further the scheme. All the speakers at this meeting were careful to state that they were carrying on the movement in no spirit of hostility to the infirmaries at present in existence. It is intended that a hospital of 120 beds shall be provided, and the sum which the committee aim at raising is about £30,000. Subscriptions are already coming in; one subscription of £1000 is promised, and another of £500, and it is confidently expected that the Town Council of Glasgow will give a site, either free or at a nominal price. The prospects of the scheme are thus brighter than might have been expected. In the course of an introductory speech at the above meeting the Lord Provost gave some interesting antiquarian information regarding the provision made by the Glasgow authorities for attendance on paupers in olden times. On 27th October, 1684, it is noted that, "considering the sad condition the town is in through the great debt it is resting owing, it is therefore concluded that the town shall make use of no person as the town's physician or chirurgeon in time coming; and if any person is unwell and deserves to be cured, upon their applying to any of the magistrates, they are empowered to recommend them to any physician they shall think fit." Further, the magistrates seem to have retained the services of a person skilled in lithotomy, for it is recorded that "a certificate having been produced in favour of Duncan Campbell, and subscribed by the haill doctors and most part of the chirurgeons in town, of his dexterity and success, they appoint Duncan to operate on the poor in place of Evir M'Neil, who is become unfit to do the same through his infirmity."

A case which has just been tried at the Glasgow Circuit Court, in which two warders were charged with murdering a lunatic pauper patient in Merryflatts Asylum, presents some points of interest. In the first place, a recently recovered lunatic, who was a patient in the asylum, was examined as a witness. The presiding judge said that this was a novelty in his experience, and that though this man's evidence was given clearly and without hesitation, he would not believe it unless it were corroborated. He was, nevertheless, not disposed to deal with the witness's statements as delusive, but thought rather that the substance of his evidence was true. In connexion with this point, it may be stated that at the Sheriff Criminal Court in Inverary, a few weeks ago, the Sheriff convicted and punished solely on the evidence of a lunatic. The evidence of Dr. Jas. Dunlop in the Merryflatts case contained a statement that it is not his practice, in dissecting a body, to open all the great cavities after finding a sufficient cause of death in one; to do more would mutilate a body, and the instructions of the Crown are to conduct post-mortems with judgment and discretion. Another medical witness expressed surprise that in the post-mortem examination of a man suffering from acute mania no examination of the brain had been made.

PARIS.

(*From our own Correspondent.*)

THE tenth annual meeting of the French Association for the Advancement of Science was held last month at Algiers, the opening address being delivered by M. Chauveau of Lyons. Prefacing his discourse by a suitable compliment to the courage of the soldiers who had conquered the country, and to the valour of the colonists who had patriotically increased and multiplied in spite of climatic difficulties, M. Chauveau began the work of the Congress by an interesting communication on "Ferments and Virus." In the medical section, the first mention is due to a paper by Professor Verneuil, on "The Surgical Aspects of Malaria." M. Verneuil thinks that the baneful influence of this poison is not sufficiently recognised by operatives. It may give rise to a number of apparently spontaneous external affections; it may unfavourably modify the progress of intercurrent or pre-existent surgical diseases; it may arrest or delay the healing of wounds, giving rise to complications of different kinds, which render the prognosis more than usually unfavourable. Traumatism in its turn reacts upon malaria, bringing it out or reawakening it in individuals in whom it would otherwise have been dormant. M. Milliot related the salutary effects produced by the drainage of Lake Fetzara, terminated last year, shown both by statistics and the decrease in the consumption of quinine. M. Landowski gave an instance of the hæmostatic properties of warm water. A patient suffering from uncontrollable hæmorrhage, due to internal and external hæmorrhoids, was placed in a hip-bath, containing water at a temperature of 35° Centigrade. This was allowed to flow freely into the rectum by means of a small speculum, and the temperature was gradually increased to 40°. After a quarter of an hour the bleeding had stopped, and did not recur. M. Henrot of Rheims read a paper advocating the treatment of Vasculo-cystic Goitre by Capillary Electrolysis, and quoted a case in support of this method. Amongst the more strictly medical communications, one of great interest was made by MM. Joffroy and Hanot on Rapidly Developed Bulbar Symptoms in Locomotor Ataxia. In one case, which the author had seen with Professor Charcot, the usual symptoms of ataxia had been wanting, a few characteristic pains only having been noticed. The patient was suddenly seized with snuffling, and at the next meal liquids returned by the nose, solid food being swallowed only after several efforts. General anæsthesia of the face, with patches of analgesia, were then discovered. The sense of taste was also affected, no distinction being made between wine, water, and milk, nor between different kinds of meat. Three months after there was incomplete facial paralysis on the right side, and two months later complete absence of tendon-reflex, paralysis of the bladder, loss of genital power, and large patches of anæsthesia on different parts of the body and limbs. There was, however, no motor coördination, and equilibrium was not disturbed by closing the eyes. Under the influence of ergot, hydrotherapy, and galvanism, a great improvement was effected in a few months, the bulbar symptoms disappearing almost entirely. In a second case, a man aged fifty, a few symptoms of ataxia had existed for a short time, when extreme weakness with motor incoördination was observed, and at the same time double facial paralysis. On the following days there were loss of muscular sense, paralysis of bladder and rectum, and darting pains in the limbs. Considerable improvement was effected in a few weeks. A memoir by M. Ziegler of Geneva on Magnetic Radiation was presented to the Congress by M. Carl Vogt. M. Ziegler believes that he has discovered that two magnetised bars of metal, joined together in a certain manner, produce certain definite effects upon animals submitted to experimentation, which differ according to the angle of intersection. One of these bars can be replaced by terrestrial magnetism. It is concluded that terrestrial magnetism radiates in the same way as light or heat, and that its rays are refracted in passing through certain bodies, such as crystals and iron. The physiological effect of magnetism can be shown by concentrating its rays through a lens of soft iron on the heart of a rabbit, when circulatory disturbances will occur. Violent peristaltic movements are provoked by focusing in the same way the magnetic rays on the intestines. M. Vogt states that he has himself observed the effects produced on the bowel, and, without giving any theoretical explanation of their mechanism, he believes that the discovery will lead to important results in physics, physiology, and medicine. Of the remaining communication made to the Congress a special mention must be given to two papers by Professor Trélat on Vesico-vaginal Fistula and Chronic Abscess; to a memoir by M. Letourneau on the Influence of Electrisation on the Temperature of Organs; and to one by M. Fleury on Hæmorrhage in Women operated on for Hernia during the Menstrual Period. A case of pulsatile tumour of the orbit by M. Gayet, and some notes on the climate of Mustapha Supérieur (near Algiers), by M. Le Blanc, are also worthy of record.

At a recent meeting of the Academy of Medicine Dr. Roussel exhibited his Herniotracteur, an instrument for facilitating the reduction of herniæ, already known to some London surgeons. It is composed of a vulcanite rod, thirty centimetres in length, terminating in a blunt hook, which is mounted on a hinge and moved by a screw. The apparatus is introduced into the rectum, and when the internal sphincter has been passed it is said to move freely in the bowel. By pushing the handle towards the coccyx the blunt hook comes in contact with the abdominal wall, and can be directed in such a way that it passes beyond the pedicle. By a turn of the screw the hook is then depressed, and made to seize the extruding loop, which has hitherto behaved most satisfactorily, returning at once into the abdominal cavity. It must be said, however, that as yet the instrument has only been tested upon the dead subject.

M. Cazin, of the Marine Hospital of Berck-sur-Mer, has published his researches on the Exploration of the Hip-joint per Rectum. He states that in young subjects the finger can always recognise a quadrilateral space corresponding to the cotyloid cavity, and which it is proposed to call the "post-cotyloid surface." This mode of examination, hitherto reserved for special cases should in future form part of the investigation in every case of coxalgia. In ninety-six cases of hip-joint disease observed by M. Cazin, rectal exploration has furnished information in forty-seven instances. The signs which can thus be noted are: pain on pressure of the post-cotyloid surface, hypertrophy of the intra-pelvic ganglia, general increase in size of the osseous surface, depression, erosion, flexibility, mobility, destruction and perforation of the post-cotyloid surface; doughiness of the soft parts, abscesses of different kinds, &c. M. Cazin believes that this method of examination will render the diagnosis of coxalgia in early cases a matter of much greater certainty.

The *clôture* of the discussion on vaccination at the Academy of Medicine having been voted at the preceding sitting, the meeting yesterday was devoted to reading the amendments, and the final vote. After a passage of arms between M. Jules Guérin and M. Blot, one of those tumultuous scenes which are so common at the Academy occurred, each member shouting, apparently for his own gratification, at the top of his voice. When the tumult had subsided, the first conclusion of the report, "That the Academy thinks it is of great public moment to render vaccination compulsory by law," was put to the vote and carried by 46 voices against 19 noes and 2 abstentions. The second conclusion, that revaccination should also be made compulsory, was also voted, with an amendment leaving discretionary executive power with municipal authorities and the councils of hygiene.

Paris, May 4th, 1881.

UNIVERSITY OF LONDON.—The following Examiners in medical and cognate subjects were elected at the meeting of the Senate held on the 27th ult.:—Practice of Medicine: W. H. Dickinson, M.D., and C. Hilton Fagge, M.D. Surgery: William MacCormac, M.Ch., M.A., and Prof. John Wood, F.R.S. Anatomy: H. Greenway Howse, M.S., M.B., and Prof. Redfern, M.D. Physiology: Prof. Arthur Gamgee, M.D., F.R.S., and Philip Henry Pye-Smith, M.D., B.A. Obstetric Medicine: J. M. Duncan, M.D., F.R.S.E., and Henry Gervis, M.D. Materia Medica and Pharmaceutical Chemistry: Prof. E. B. Baxter, M.D., and Prof. F. T. Roberts, M.D., B.Sc. Forensic Medicine: Prof. George Vivian Poore, M.D., B.S., and Thomas Stevenson, M.D. Chemistry: Prof. Debus, Ph.D., F.R.S., and Prof. Dewar, M.A., F.R.S. Botany and Vegetable Physiology: W. T. Thiselton Dyer, M.A., B.Sc., F.R.S., and Sydney H. Vines, D.Sc., M.A. Comparative Anatomy and Zoology: Prof. E. Ray Lankester, M.A., F.R.S., and Prof. A. Milnes Marshall, D.Sc., M.A.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Licentiates of the College on April 28th:—

Barns, John Gay, Falmouth-road.
Davies, David Samuel, Queen-square, Bristol.
Duncan, William Archdeckne, M.D., Croydon.
Evans, Arthur Owen, St. George's Hospital.
Fenton, Herbert Alfred Hill, Cumberland-street.
Havell, Charles Graham, St. Mary's Hospital.
Heaven, John Cookesley, Kennington-road.
Hoskin, Theophilus, Stratford-on-Avon.
Houlgrave, Augustine, Reedworth-street.
Little, Ernest Muirhead, Park-street.
Marsh, Thomas Alfred Perry, Bristol.
Marsh, William Aspinall, Hindley, Wigan.
Mattice, Richard Iram, M.D., Horton-road.
Mudge, Thomas Henry Tracey, St. Bartholomew's Hospital.
Newmarch, Bernard James, Doughty-street.
Ozanne, Frederic Newell, St. George's Hospital.
Penny, William John, King's College Hospital.
Phipps, Edgar Vivian Ayre, St. Luke's Hospital.
Smith, Ernest Sutton, Fitzroy-road.
Taylor, Henry Herbert, Morden-terrace.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners during the past and present week:—

Harry C. C. Shaw, Louis Robinson, Alexander Harper, Montagu Smith, Henry G. Wharry, Edgar W. Willitt, Richard B. D. Batt, Herbert L. Dowsing, Charles O'B. Harding, Francis F. Walton, Arthur Hillaby, William R. de Morinni, Stephen Paget, Conistan Spackman, and Thomas Finch, St. Bartholomew's Hospital; Arthur E. Larking, William Fowler, Arthur H. Dodd, Charles S. Jago, Allan G. Minns, Herbert J. Dring, Edward W. Simmons, Henry T. Tresidder, William H. Brenton, C. W. Crealock, Magnus M. Adler, and John H. H. Manley, Guy's Hospital; Thomas E. Gordon, Leonard J. Willan, William J. Best, Wilfred J. Hadley, Robert H. Nicholson, Edward H. Morgan, Daniel B. Spence, and Matthew C. Corner, London Hospital; Charles F. Clarke, William C. McDonnell, and Joseph J. W. Farr, Charing-cross Hospital; Thomas F. Forster, Nathaniel H. Turner, John H. Gostling, Charles L. Sanson, William Habgood, James T. Chevers, Herbert C. Dent, and Ernest Cusse, King's College; James A. J. Murray, Archibald McKenzie, Samuel G. Campbell, and Joseph J. Stapleton, Edinburgh; Thomas P. Gostling, John C. Jackson, Charles L. Lempriere, and James E. Blomfield, University College; Reginald M. Williams and Lewis D. Brown, St. Thomas's Hospital; Robert R. Williams, Glasgow and King's College; Gerald Callender and Arthur H. L. Stewart, St. Mary's Hospital; Jonathan Royston, Joao G. D'Aguiar, William Livermore, Philip B. Bentlif, William D. Stevenson, and R. Mills, Middlesex Hospital; William Urwick, Westminster Hospital; Henry A. de Lom, Toronto and St. Thomas's Hospital; Laurie A. Lawrence, Henry F. Horne, and Frederick C. Wallis, St. Bartholomew's Hospital; William H. L. Marriner, Henry M. Sutton, and John L. W. Kitching, St. Thomas's Hospital; Owen W. Roberts, St. Mary's Hospital; Ernest J. G. Berkeley, Charing-cross Hospital; Charles D. Muspratt, Guy's Hospital; Thomas D. Richards, Edinburgh, and King's College; Matthew R. Gooding, University College.

Of the 185 candidates examined during the past fortnight, 53 failed to satisfy the Board of Examiners, and were referred for three, and 3 candidates for six, months' further anatomical and physiological study.

APOTHECARIES' HALL.—The following gentleman passed the examination in the Science and Practice of Medicine, and received a certificate to practise, on April 21st:—

Wyborn, Samuel, Sussex House, Windsor.

The following gentlemen passed on the 28th:—

Dixey, Arthur Crosbee, Cheltenham.
Russell, John Hutchinson, Plaistow, Essex.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Richard Holton, Queen's College, Manchester; David Thomas Key, Guy's Hospital.

DR. PHILLIPS has been placed on the Commission of the Peace for the borough of Carmarthen.

UNIVERSITY OF DUBLIN.—On the 29th ult. the degrees of B.S. and M.B. were conferred on Hamilton Maginnis Sproulle.

THE Duke of Connaught has signified his intention to support his brother, Prince Leopold, at the festival dinner of University College Hospital, to be held at Willis's Rooms on the 20th inst.

THE GERMAN HOSPITAL.—At the thirty-sixth annual festival of this charity, held on the 3rd inst., it was stated that the in-patients during the past year numbered 1476, the out-patients 19,453. The income had been £9195, and the expenditure £8738.

AN amateur concert was given last week in Cork, in aid of the Hospital for Women and Children. The performance was highly commended, and it is believed that a substantial sum was obtained for a highly deserving charity.

MEATH HOSPITAL.—Lord and Lady Brabazon have offered portion of a house, consisting of five bed-rooms and a sitting-room, at Bray, free of rent for the use of convalescent patients belonging to the hospital. It is understood that no patient suffering from an infectious malady will be admitted.

THE management of the lunatic asylum at Wellington, New Zealand, is undergoing scrutiny at the hands of a commission of inquiry. Charges of a serious nature have been made against some of the officials of the asylum. The fact that one of the commissioners appointed is a visiting justice has excited unfavourable comment.

ST. BARTHOLOMEW'S HOSPITAL.—The accounts of St. Bartholomew's Hospital for the past year show that the amount of cash "available for hospital purposes" was £77,100 16*s.* 8*d.*, and that at the end of the year there remained a balance of £5686 0*s.* 3*d.* in favour of the institution.—*City Press.*

AT a meeting of the governors of the Essex and Colchester Hospital, held recently, Admiral Luard moved that a special committee be appointed to inquire into the administration of the hospital, in order, if possible, to reduce the expenditure, the financial condition of the institution being unsatisfactory.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for successful vaccination in their respective districts: Dr. Scoresby-Jackson, Walthamstow (first time). Mr. James Allen, Bollington (fourth time). Mr. L. Nicholls, Hartest, Bury St. Edmunds (second time). Mr. C. J. Stocker, Upton.

THE Corporation of Wigan opened the Sewerage Works at Newburgh on April 26th with civic honours, about sixty persons being present. The works are on the irrigation principle, and will cost £72,000. A banquet was afterwards held at Southport, the Corporation being entertained by the Mayor of Wigan.

THE Honorary Medical and Resident Officers of the *Dreadnought* Seamen's Hospital have just presented to Mr. Henry C. Burdett a carved oak library table, as a mark of esteem and as a recognition of their appreciation of his successful labours during the period he has had the management of the Greenwich Hospital.

UNIVERSITY OF EDINBURGH. — The Vans Dunlop Scholarship in Surgery and Physiology was recently awarded to George Fisher; the Senior Mackenzie Bursary divided between Messrs. William Hunter and C. W. Jones, and the Junior Mackenzie Bursary awarded to Paul Bowes; the Junior John Aitken Carlyle Bursary was awarded to Harold J. Stiles.

SOUTH LONDON SCHOOL OF PHARMACY. — The prizes were awarded at the examinations ending 2 B. Course, and presented on the 30th April, 1881, to the following successful competitors: Senior Chemistry Medal, Mr. Thomas; Junior Chemistry Medal, Mr. Shaw; Botany Medal, Mr. Bull; Pharmacy Medal, Mr. Walker; Materia Medica Medal, Mr. Kay.

ROTUNDO LYING-IN HOSPITAL, DUBLIN.—At a meeting of the Public Health Committee of the Corporation of Dublin held last week, a report from the secretary was read, stating that the most effective means were being adopted by the governors of the hospital for improving the sewerage, to the defective condition of which we recently referred.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the College held on Monday, the 2nd inst., the following were elected examiners for the ensuing year:—Examiners for Letters-Testimonial and Fellowship: Henry Gray Croly, William Frazer, Benjamin G. McDowel, Edward Stamer O'Grady, Benjamin Wills Richardson, Edward A. Stoker, Robert S. Swan, and Wm. Thomson. Examiners in Midwifery: John J. Cranny, Henry Croly, and William J. Smyly. Examiners in General Education: Michael Joseph Malone, Robert Morton, and Henry Tweedy.

A FESTIVAL dinner in aid of the funds of the Middlesex Hospital will be held at Willis's Rooms, King-street, St. James's, on Friday, May 13th, 1881, at which the Right Hon. the Earl of Derby has consented to preside.

THE Hospital Saturday collections took place at Sheffield on Saturday last, and the amount paid into the bank up to the 2nd inst. was £924 4*s.* 4*d.*, of which £846 3*s.* was subscribed by workmen, and £78 0*s.* 6*d.* collected in boxes in the streets. Last year, £1193 8*s.* 5*d.* was collected.

OXFORD UNIVERSITY.—It has been announced that examinations for the degree of Bachelor of Medicine will be holden in Trinity Term, as follows:—The First (or Scientific) Examination will commence on Monday, June 27th, at 10 A.M. The Second (or Final) Examination on Monday, June 13th, at 10 A.M. The names of candidates for either of these examinations, and of candidates for the certificate in subjects bearing on Preventive Medicine and Public Health, should be sent on or before May 30th, to the Regius Professor of Medicine, Medical Department, Museum.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—9 P.M. Mr. F. Galton, "On Mental Images and Vision."
CLINICAL SOCIETY OF LONDON.—8½ P.M. Report of the Committee on Excision of the Hip-joint.—Dr. Whipham, "On a Case of Aneurism of the Aorta, demonstrated during life by the Laryngoscope."—Dr. T. Stretch Dowse, "On a Case of Anorexia Nervosa."—Mr. A. P. Gould, "On a Case of Rapid Death after Antiseptic Osteotomy of the Tibia."—Dr. Wiltshire, "On a Case of Traumatic Rupture of an Ovarian Cyst."

Saturday, May 14.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Professor H. Morley, "On Scotland's Part in English Literature."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"CLINICAL ANATOMY."

IN a lecture delivered before the Anatomical and Surgical Society of Brooklyn, U.S.A., Dr. W. W. Keen of Philadelphia, Professor of Artistic Anatomy in the Pennsylvania Academy of Arts, gave some hints in respect of the best method of teaching clinical anatomy, which are worthy of reproduction. After demonstrating a portion of his subject by means of casts and prepared bones, Dr. Keen continued (we quote from the *Boston Medical and Surgical Journal* of April 14th):—

"But turn from the cast of the dissection to our living model. Let an observer call the muscles of the knee into vigorous action, and then note here the high external vastus, there the lower and stouter internal, here the patella, and there the 'supra-patellar flat,' as artists call it—i. e., the tendon chiefly of the rectus, and here the ligamentum patellæ, and then, if never before, you will appreciate not only the facts to which I have asked your attention, but also the value of this method of studying anatomy. A living interest is added which the cadaver cannot give; muscles can be relaxed or contracted and their reliefs studied in relation to vessels, nerves, or other neighbouring organs of importance; the lungs can be perceived in expansion and contraction; the position of the stomach, the liver, the intestines, the bladder, &c., can be shown; the course of the arteries exhibited; movable bones shown in various positions; the relation of parts in different postures shown clearly, and in their relations to medicine, surgery, obstetrics, &c., and all demonstrated at the time of most importance—i. e., the very moment when they are being studied. . . . I venture to affirm that the living model should form as indispensable a part of the means of illustration in the anatomical lecture-room as the cadaver. In not a few respects, indeed, is it even more important. If its inconvenience and expense be urged, I may remind you that one model we always have—ourselves,—and it is surprising how much anatomy we may learn from studying our own bodies."

ESSAYS ON DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In last week's LANCET I notice you state that the jurors appointed to examine the essays on diphtheria, which have been sent in response to the invitation of the Empress of Germany, who offered a prize of £100 for the best essay, have not awarded the prize on account of want of merit. Now, it was expressly stipulated that the essays were to embody the personal experience of the writers, also that the object of the donor was to bring out facts relating to the successful treatment of the disease. As I was one of the many competitors, it is not to be wondered that I take a deep interest in the verdict of the jurors. Moreover, I adduced evidence from two independent sources, which was sent to me unsolicited, to prove that the treatment I advocated has resulted in the cure of close upon 300 consecutive cases. These statistics were sent to me by two medical men whom I had never seen or heard of before. I also showed that the treatment in my own hands had been most successful, and I certainly feel that all that was required by the advertisement inviting the profession to give their views and experience on the subject was fully carried out by me.

I sent in my essay in the beginning of December last, and although I wrote several times asking if it had arrived, I could not by any means get an answer from Berlin, and up to this date I have heard nothing about it. Such want of courtesy I never received at the hands of anyone in all my previous experience, and certainly I will never lay myself open to such treatment again at the hands of those in authority in Berlin. It seems strange that of all the essays, sent in, as they were, from all parts of the world, not one satisfied the jurors.

I am, Sir, yours sincerely,
COMPETITOR.

April 27th, 1881.

STATISTICS OF SUICIDE.

A RECENT number of the *St. James's Gazette* contains the following :—

> "Signor Morselli, director of the lunatic asylum in Macerata, has just published some interesting statistics about suicide, based on 300,000 officially reported cases. It appears from these returns that suicides are most frequent in the spring and early summer, and between the hours of six and twelve in the day. The greatest number of suicides occur among the Southern and Central Germans; the Northern peoples come next, and the Southern Slavs, the Roumanians, and the Latin races last. Protestants commit suicide more frequently than Catholics, and Catholics than Jews; among Mahommedans suicides are very rare. As a rule, an increase in the number of suicides is accompanied by an increase in the number of criminals; but thieves more frequently commit suicide than murderers, and four times as many men commit suicide as women. The causes of suicide in southern countries are chiefly love and poverty; in northern countries, drunkenness; and in central Europe, *ennui*, shame, and the fear of punishment."

Dr. Justus Andeer (Würzburg).—The pamphlet has not come to hand.

Brigade-Surgeon Cattell is thanked.

Surgeon-Major, A.M.D.—Our correspondent could not have read THE LANCET of March 10th before writing his letter, or he would certainly have omitted the first two pages of it. With regard to his suggestion in the latter part of his letter, surely he must be aware that there is no such thing as brevet rank in the A.M.D.

H. A. T. should consult a surgeon.

Dubitans.—There is no rule for circumstances so unusual. Our correspondent should intimate that while willing to attend in exceptional circumstances for an absent brother, he cannot do so frequently without an understanding that he is to have half the fee.

An Inquirer.—Certainly not.

"DISLOCATION OF SHOULDER-JOINT AND DEATH FROM CHLOROFORM."

To the Editor of THE LANCET.

SIR,—The remarks of Mr. Lawton on the great number of fatalities attending the use of chloroform during the reduction of dislocations of the humerus, and the plan laid down by him in your impression of the 26th ult., enabling the surgeon to dispense with so dangerous an anæsthetic, will doubtless meet with general approval, but I am not one of those who pin their faith to the "heel in axilla" plan, or to any other system which is based on the application of physical force, which I believe may in a vast number of cases be dispensed with altogether. This may appear to some a somewhat startling assertion, but it is none the less a fact, and, by your kind indulgence, I will now give to your numerous readers the benefit of my experience in these particular cases, which, though limited as to number, has extended over a period of upwards of thirty years, and refers to dislocations of the humerus into the axilla only.

The plan I adopt is the following, which requires no assistant, no extension, counter-extension, or even fixing of the scapula, is almost entirely painless, and the reduction is accomplished in half a minute, or a minute at most.

I take firm hold of the elbow (bent to a right angle) of the affected arm, raise it as nearly to the perpendicular as possible, and keep it there closely pressed against the acromion; I next pass two or three fingers of my left hand, with their palmar aspects outwards, underneath and behind the head of the bone, which is now pointing directly downwards below and outside the glenoid cavity of the scapula, until they reach the lower edge of the latter, and having insinuated my fingers in some measure between them, by which means a fulcrum is formed, I now firmly and rapidly draw down the wrist with a sweep, and the head of the bone glides over the fingers, and slips into its place.

It may appear at first sight a difficult matter to insinuate the fingers of the left hand as directed, and it would be so but for the natural flaccidity of the integuments in the axillary space. I can assure your readers I have never yet experienced any difficulty in the reduction of a luxation of the kind mentioned; but all those who adopt the plan I recommend must expect a slight pinch of the fingers at the moment of the reduction.—I am, Sir, your very obedient servant,

CHAS. H. GREENE, L.S.A. Lond., &c.

Beverley-road, Barnes, S.W., April 26th, 1881.

W. M.—A case in point, at the Marylebone County Court, will be found in THE LANCET of March 6th, 1875. The principle has been frequently recognised, but we are bound to add that county court judges often find excuses for departing from it.

Quercus.—It is customary to do so.

Tea-planter.—We are not aware. The inquiry should be addressed to some agent, or, as regards *public* appointments, to the office of the Secretary of State for India.

A. G.—There is no justification for such loose proceedings. The coroner cannot have been a medical man.

MICROSCOPES.

A Colonial Surgeon should send his microscope to the makers and request them to put it in order for him. If he is then unable to see his specimens he should ask a friend to put him in the way of using the instrument. If he has no friend to help him, he will obtain the information he requires in Carpenter's work on the "Microscope."

PRESERVATION OF VACCINE LYMPH.

A Correspondent asks for information as to the best method of pr serving fresh vaccine lymph on points. He has tried sealing them gutta-percha tissue without success.

G. W. R.—The paragraph is doubtless in very bad taste, but the respon sibility for its publication may not lie with the gentleman belauded.

Inquirens.—Two.

Sanitas suggests that Dr. Alfred Hall's patent ventilator should be used in railway carriages.

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—The following translation of an article in No. 102 of the *Cologne Gazette* (1881) will be interesting as a hint to the solution of the important question raised by Dr. Mortimer-Granville, and ventilated by others, in THE LANCET :—"A Contribution to solve the Question if the Sex of the Offspring of the Cow may be determined before Birth?" "Although man has from the earliest times onwards tried to obtain information on the origin of sexes—viz., Hippocrates and Galen—he has not yet been able to lift the veil, and the best known breeders of the present time are compelled to acknowledge their ignorance of the subject; thus we might be led to think that it was necessary for the preservation of species that the secret should never be discovered.

"The advantages, however, which would accrue to breeders if the sex could be determined beforehand are so great that we cannot be astonished at the pains which have been taken to bring some light to bear on the question, and as we cannot deny that it might possibly have some influence on the determination of sex, we must carefully examine all the attempts made in this direction. Dr. H. Fanke gives, under the title 'The Predetermination of Sex in the Cow,' an account of such an attempt which an American gentleman, Mr. D. D. Fignet, has made in Horeston (Texas). This practical breeder was soon struck by the fact that when a strong and eager bull was coupled with a cow which did not show marked signs of eagerness, female births were always more numerous, and *vice versâ*. In order to make use of this observation in the practical breeding of animals, it would be necessary to arrange their food and training in such a way as to increase the sexual desire of one and not of the other. Mr. Fignet, therefore, followed the rule never to allow a cow to be brought into contact with the bull during her first period of excitement, but, on the contrary, he always noted the day of its commencement, in order to know the exact date on which it might be again expected, so as to make fitting preparations before this took place.

"Now, it so happened that he wished to obtain a bull calf from a very valuable cow, and following the precept that the animal which during the sexual process is sexually strongest determines the birth of an animal of the opposite sex [the physiological fact to which Dr. Mortimer-Granville directed attention], he began at once, after the cow's first period, to feed the animal very abundantly until the next. He, on that account, fed the animal for two weeks on his richest pasture land, and, besides, gave it that food which from experience is known to stimulate sexual desire. During the latter part of the last week he stalled in and fed it with care. The bull, on the other hand, he was going to use was fed on light food during the same three weeks. When the period arrived he found that the cow showed a very strong sexual desire, whilst the bull did not appear to be very eager. The result was what had been expected, the cow giving birth to a very fine bull calf. But as it was the breeder's interest afterwards to breed cows for his dairy, he simply tried the opposite process, and each single cow gave birth to a fine cow calf. The breeder, Mr. Fignet, says that he has caused thirty attempts to be made, and that he has always, without exception, had an animal of the sex he wished to get, and, resting on this basis, he thinks that he has arrived at perfection and has found the way to determine the sex of the calf nearly one month in advance. The number of the attempts thus made is as yet too small to test by them only the truth of Mr. Fignet's rule, and we must wish therefore that other attempts be made to throw some light on a question which is of such grave importance to the breeders of cattle. The object of writing these lines is to induce breeders to make such attempts, but intending observers should first study the book of Dr. Fanke, as the short notes which we have given above are not sufficient to throw light enough on the question." When I receive the book of Dr. Fanke, as ordered, I shall send you more particulars on the important matter.

I am, Sir, yours, &c.,

Bad Kreuznach, April 28th, 1881. Dr. PRIEGER.

THE TREATMENT OF PSORIASIS BY TURPENTINE.

To the Editor of THE LANCET.

SIR,—In the local treatment of psoriasis, as in all other obstinate and chronic diseases, a very large number of drugs and methods of procedure, mostly with a view to stimulate the parts, have been employed with more or less success, and often recommended with more than corresponding zeal. No one plan is applicable to all cases. Thus some are actively hyperæmic, and any stimulant at the onset will be injurious; others require only mild stimulation; while a very numerous class require a very strong irritant if anything beyond very slow progress is to be obtained, but that stimulation must be of a special kind. Tar is a well-known remedy of deserved reputation, but it is often very slow in its action, and its disagreeableness is obvious. Chrysophanic acid has acquired a great reputation of late years, on account of the rapidity with which it removes the eruption in suitable cases. Few, however, would care to have it used upon the head on account of the purple colour it imparts to the hair and its producing swelling, erythema, and perhaps conjunctivitis when used near the face. While according to the acid a far higher position than I once did, its drawbacks and limitation have long led me to try other remedies. Three years ago I advocated thymol, and I still use it, especially for the head and face, as it is one of the most agreeable remedies we possess both for psoriasis and ringworm. It is often necessary, however, to use it in the proportion of one drachm to four drachms dissolved in an ounce of lard—i. e., much stronger than I first used it. Still, it is less rapid in its action than chrysophanic acid; and lately turpentine, on account of its being a powerful and penetrating stimulant, occurred to me as an application likely to be of service, the efficacy of the acid seeming to be due to its being a penetrating and diffusive stimulant. Cautious trials were at first made with one or two drachms of turpentine to one ounce of olive oil, but while this was sufficient for some cases, I soon found that pure turpentine well rubbed into the eruption was often advantageous, smearing the parts over with vaseline afterwards to obviate the desiccating action of the turpentine. This I found removed the eruption so rapidly that when a severe case of general psoriasis presented itself I resolved to compare the turpentine with chrysophanic acid by applying them upon opposite sides of the body. The result—namely, that the eruption was simultaneously removed from both sides, and from which I inferred that the two drugs were of equal value, at least in this case—I demonstrated at the Medical Society, and it has evoked much correspondence in your columns. A "Glasgow Student" suggests that the acid alone was the efficacious agent, because Dr. Charteris wrapped up one limb in cotton-wool and anointed the other with chrysophanic acid, and both got well together. The experiment is suggestive, but not conclusive, for wrapping the limb up in wool and confining thus the perspiration is in itself a treatment, while the theory is effectually disposed of by the facts that turpentine when used alone suffices for the rapid removal of the eruption, and I have used it in many cases since the one shown at the Society; further, that when tar or other remedies of acknowledged inferiority are tested comparatively with chrysophanic acid, both sides do not get well simultaneously. While turpentine is clean and cheap, its main drawback is the odour. This may to some extent be covered with oil of lavender; still it is a disadvantage, and must be balanced against the dyeing and erythema-producing qualities of chrysophanic acid. I am not, however, anxious to vaunt turpentine as a new specific for psoriasis, but rather to point out that by intelligent research we may hope to attain to the ultimate aim of treatment represented by the motto "Cito, tuto, et jucunde." I have not gone into the management of psoriasis by internal means. To remove the eruption is one thing, but to prevent or postpone its return is only to be effected by careful hygienic and medicinal treatment adapted to each case, the success of which depends upon the judgment of the physician, seconded by the patient's care and ability to carry out his directions.

I am, Sir, yours obediently,

Welbeck-street, April, 1881. H. RADCLIFFE CROCKER, M.D.

Contributor and others enclosing pamphlets and circulars relating to homœopathy are thanked. The advocates of the "system" are not unnaturally stirred to new forms of enterprise by recent events.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

A Lecture

ON THE

PHYSIOLOGY AND PATHOLOGY OF THE OLFACTORY NERVE.

Delivered at the Hospital for Epilepsy and Paralysis, Regent's-park.

BY JULIUS ALTHAUS, M.D., M.R.C.P.,
SENIOR PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—The olfactory nerve, although the first in anatomy, is generally credited with being the least useful to man in a state of civilisation. Indeed, if we compare it with its more immediate associates—namely, the optic and auditory nerves, without which life, as we understand it now, could not be carried on,—it seems to recede into an immeasurable distance. If Prince Bismarck and M. Gambetta were to become suddenly blind and deaf, the destinies of Europe would no doubt be changed; while if these two men were to lose their smell and taste, things would probably go on much in the same manner as they do now. The sense of smell is, however, acknowledged to be of vital importance to animals. Sir John Lubbock has discovered that ants are, not only in their search for food, but also in their actions generally, guided by this sense, which resides in their antennæ. It is by the smell that they recognise friends and foes, and are impelled to do their work; for with the exception of the winged queens and their husbands, most ants are blind, and the world is known to them only as a succession of different and well-defined smells. Some fish, like the perch, trout, and salmon, are guided in their actions more by the sense of sight, which is largely developed in them; while the shark, on the other hand, is chiefly a smelling fish, its nose being so enormously developed that the mucous membrane of it, if unfolded, would cover an area of twelve feet square. In birds smell is rudimentary, and sight wonderfully keen; while moles have large organs of olfaction, and eyes scarcely indicated. Many herbivorous animals are enabled, by their keenly-developed sense of smell, to avoid poisonous plants, and select nutritious ones to feed upon. Smell to them is, as it were, the sentry of taste, guarding the approach to the palate. It informs animals of the manner in which a certain thing will affect them, so that they know what to seek and to avoid. It gives to rabbits, hares, deer, and other animals which have to rely for their safety rather on rapidity of flight than on their strength, early notice of the approach of an enemy, and thus affords time for escape from danger. The carnivorous class may, on the other hand, by the scent, detect their prey sooner, and surprise it more readily.

The sense is also of importance for the reproduction of the species, since animals of opposite sexes are thereby attracted to each other. This is more especially the case with the musk deer, the civet cat, and the beaver, whose preputial follicles secrete musk, civet, and castoreum, but it is more or less so with all animals whose sexual organs develop a peculiar pungent odour during the period of rut. For the dog the olfactory nerve is the great ruler of life. A dog which is deprived of smell may almost be said to have ceased to be a dog, for that animal, as Schiff has shown by section of the nerves in puppies, loses with its smell its faculty of attachment and faithfulness to its master, whom it recognises and loves simply on account of his individual perfume. Schiff's deolfactorised puppies were throughout life indifferent to their master, although he treated them with the greatest kindness.

No doubt the olfactory nerve is also of considerable use to man in a state of nature, in the same way as to animals; and the peculiar pigment which surrounds the terminations of the nerve, and appears to serve for a readier absorption of odours, is even now more developed in the coloured and savage races than in the white man, where the nerve is more rudimentary. The nostrils of negroes are particularly large, and contain sinuses for increasing the olfactory surface, which are not found in the Caucasian race.

To ourselves this nerve does not offer much protection, for some poisons, like hydrocyanic acid, have an agreeable odour, while we cannot distinguish edible from poisonous mushrooms by the smell. Yet it gives us a quick indication of a gas-escape in our dwelling-houses, and no doubt gas explosions have thereby been prevented. Nor should we forget that our arrangements for the disposal of sewage owe their perfected state in a great measure to the reminders which the nose has given us to attend to them; and indirectly, therefore, a vast number of lives have been saved by its instrumentality.

The olfactory nerve, however, comes chiefly into play during our meals—indeed, we appreciate the flavours of meat and drink solely by the olfactory, and not, as is commonly believed, by the gustatory nerve, which latter conveys to us only the four fundamental tastes of sweet, bitter, acid, and saline, but no aromas or flavours. The art of dining would therefore be lost if we were to be deprived of the sense of smell. Tea, coffee, wine, and other articles of diet which are chiefly appreciated for their flavour, would greatly decline in popularity. Our social life, in which dinners play so conspicuous a part, would assume an entirely different aspect; such a book as Brillat-Savarin's "Physiologie du Goût," which treats of the flavours of dishes, would become unintelligible, and we cannot, without shuddering, imagine the probable condition of the aldermanic mind if turtle soup were to become a vain conceit.

Dyspepsia and congestion of the liver would most likely increase rather than diminish if we had no smell, for although excesses at table are no doubt promoted by the pleasing flavour of the dishes put before us, and might, therefore, no longer occur in the same ratio as now, yet, on the other hand, we should certainly often partake of unsuitable and indigestible food, more especially of putrid meat and fish, if ourselves and our cooks were unable to discriminate by smelling that which is nasty from what is nice. Moreover, if eating gave us no pleasure, but were only done from necessity, we should probably fall into the habit of hurrying through our meals and bolting our food, which we know to be a prolific cause of indigestion.

The flavour of a fine cigar is only appreciated by the olfactory nerve, and smoking would therefore probably decline if we had no smell. As it is generally admitted that the temper of man is softened and soothed by tobacco, the coarser side of our nature might assert itself more if we were deprived of the "weed." Yet it is a singular fact that men have continued smoking after having lost their smell; while others have given it up after having become blind, and when smell persisted. This would appear to prove that the sight of the rising curls of tobacco-smoke enters as much into the enjoyment of a cigar as its flavour.

If we had no olfactory nerves the science and art of perfumery would vanish, Bond-street would be shorn of one of its greatest attractions, and ladies could no longer heighten their charms by the use of delicate scents. Even now the relation between the sense of smell and the tender passion is not quite extinguished; and Hippolyte Cloquet, in his "Osphrésiologie," or science of odours, says: "La saison des fleurs est celle des amours; l'odeur qui s'exhale de leur sein épanoui, en parfumant le zéphyr, fait entrer au fond du cœur un charme irrésistible. Les idées voluptueuses se lient à celles des jardins et des ombrages odorans; et les poètes attribuent avec raison aux parfums la propriété de porter dans l'âme une douce ivresse." This is no doubt the reason why hysteria, which was formerly believed to be a disease of the womb, was of old chiefly treated with strongly smelling substances, such as musk and castoreum; and where these could not be procured, by the emanations from burnt feathers or wool. Such treatment was indeed recommended by the Father of Medicine, who also spoke highly of the effects of sweetly smelling oils introduced into the vagina during hysterical fits.

Another art which would decay if smell were lost is that of horticulture; for roses, jasmine, hyacinths, and many other fragrant flowers, are cultivated much more for the pleasure they afford to the nose than to the eye.

That the first cranial nerve is intended for olfaction, or, more strictly speaking, for conveying odorous impressions to the brain, was first laid down by the learned monk Protospatharius, who wrote, about the year 800, a Greek essay on the parts of the human body. Aristotle has, indeed, credited the nose with being the seat of the sense of smell; but Galen, in his treatise "De Instrumento Odoratûs" stated that the olfactory nerves were simply canals by which vapours arrived in, and humours escaped from, the brain, and that the sense of smell resided in the anterior cerebral ventricles. He was no doubt led to this conclusion by his dissections of quadrupeds, in which the olfactory lobes contain cavities filled with serum, and communicating with the lateral ventricles. Such cavities exist even in the human fœtus at an early period of its development. Moreover, Galen had observed that smell was bound to inspiration, which seemed to him to show that odours passed bodily into the cerebral substance. Vesalius was the first to dissect the olfactory nerve in the human subject; he described its external and internal white roots as well as the olfactory ganglion, and agreed with Protospatharius as regards its function. Lobstein first noticed the third central grey root, which only comes in view if the nerve is pulled aside.

From that time forward the olfactory nerve was generally admitted to be concerned with smell, but Magendie, to whom experimental physiology owes so much, concluded from his experiments on dogs that smells were perceived by the nasal branches of the fifth pair, and that the first nerve was a structure like the pineal and pituitary glands, the functions of which were as yet problematical. The substances with which Magendie experimented were chiefly ammonia and strong cheese, and as these affect common sensation as much as the special sense of smell, it was justly objected to these experiments that no sufficient distinction had been drawn between ordinary and special sensibility. This view was generally endorsed by physiologists until Claude Bernard in his lectures on the "Physiology and Pathology of the Nervous System" (Paris, 1858) reopened the question, and without actually upholding the theory of his illustrious predecessor, adduced arguments to prove that we were not yet in a position to speak decisively on the relative functions of the first and the fifth nerve. He argued that the analogy with vision, for which there is a special nerve, did not prove anything, as there was a contrary fact concerning taste, the gustatory nerve having been shown to preside over common as well as special sensibility in the two anterior thirds of the tongue.

Bernard supported his argument chiefly with a case of congenital absence of the olfactory nerves, which happened accidentally to come under his notice on the post-mortem table. It was the case of a woman who had died of phthisis in the Hôtel Dieu. On opening the skull it was found that the cribriform plate of the ethmoid bone did not exist, or rather that it had no foramina; the sulcus in which the olfactory nerve usually lies was only slightly indicated, and there was no trace of these nerves anywhere, not even towards their habitual origin. In all other respects the brain and cranial nerves were perfectly normal. On inquiry amongst her friends it turned out that no deficiency of smell had been recognised or suspected in the patient during life. The woman had been known to have a great dislike to tobacco, and when she entered a room the first thing in the morning, where people had been smoking the previous evening, she would hasten to open the windows in order to get rid of the stale smoke. She had also frequently complained of the stench from a privy which was close to her room; she was a good cook, and cunning in the preparation of fine sauces and dainty dishes. Moreover, she had been fond of flowers, which she was in the habit of putting to her nose; she had suffered from profuse night sweats, and complained of their disagreeable odour, and she had refused to take medicines which had a nauseous flavour. With all this she had never had any olfactory nerves! This case is certainly singular, yet we should consider that all the information concerning it was obtained secondhand, and not from the patient herself; and it may be that she had, after all, only perceived such substances as ammonia and sulphuretted hydrogen, which act not only on special but also on common sensibility, and that her habit of putting flowers to the nose was merely a pantomime devoid of special meaning. Indeed, one often notices women, especially those of a lively temperament, carrying flowers to the nose which are devoid of smell, like camellias.

More recently a considerable amount of evidence has been brought forward which indisputably proves that the first cranial nerve really has the special function of smelling, and that the branches of the fifth nerve and the spheno-palatine ganglion, which supply the Schneiderian membrane, are only intended for common sensation and reflex action. In 1868 a case came under my care at the hospital in which there was complete anæsthesia of the fifth pair of cranial nerves, the patient being deprived of common sensation as well as of the senses of temperature, touch, and locality, all over the scalp, face, and in the mucous membranes of the eyes, nose, and mouth, without any other disease whatever. In that case, which I brought at the time before the Royal Medical and Chirurgical Society, and which is published in its Transactions for 1869, the mucous membrane of the nose was perfectly insensible to the touch of blunt or sharp instruments, and no sneezing was brought on by snuff; yet the sense of smell was perfectly normal, the patient having no difficulty whatever in appreciating the different varieties of scents with which I tested him. It was thus rendered evident that no intervention of the trifacial is necessary for the appreciation of odours, which is, on the contrary, the special function of the first pair.

Physiological experiments in animals, which have since been made, have confirmed the view which I then expressed. Thus Schiff noticed that after section of the olfactory nerves or lobes in puppies, these were unable to find the teats of the bitch; they would sip milk from a saucer, but when it was covered with paper they failed to find the milk. Again, if the edge of the containing vessel was besmeared with some foul-smelling substance, which would deter any ordinary dog from touching it, the deolfactorised puppies would drink the milk all the same. Vulpian destroyed the olfactory lobes in bloodhounds, and kept the animals some time without food. They were then found unable to discover meat concealed somewhere in the laboratory. Prévost excised both spheno-palatine ganglia, which Bernard had suspected to be concerned in smelling, yet that sense remained perfect. It was, however, lost when the olfactory nerves were afterwards destroyed in the same animals.

It is a significant fact that chemical, mechanical, and thermic irritation of the olfactory nerves in animals causes neither pain nor movement, nor reflex action of any sort, and this points clearly to the sensorial function of the nerves. Comparative anatomy shows their large development in animals whose smell is notoriously keen.

Does this nerve respond specifically to the application of electricity? This is an interesting question which has engaged the attention of physiologists since the discovery of galvanism towards the end of the last century. It is well known that the optic nerve responds to the continuous voltaic current by the perception of flashes of light, the auditory by peculiar sounds, and the gustatory by a special taste. Any special sensorial response of the olfactory nerve, however, had not been observed until I demonstrated it in the patient to whose case I have just alluded as one of disease of the trigeminal nerve. That such an effect should have escaped the notice of so many previous observers I attribute to the fact that a current of great power is required for making an impression on the first pair; and a strong current affects at the same time the fifth, the optic, the auditory nerves, and the brain itself, so much that a commotion is caused in the latter, which renders it unable to properly differentiate so many powerful simultaneous impressions. The application of a current of thirty-five pairs of plates to the mucous membrane of the nose, which I found necessary to elicit a response of the olfactory nerve in that case, produces in persons who are in their ordinary health extreme pain, dazzling flashes of light, a hissing noise like that of a steam-engine, together with faintness and giddiness. In the patient referred to, however, such a current could be easily borne on account of the anæsthesia which was present; and in him the perception of a *phosphorous smell* occurred so constantly when this proceeding was used, that it was rendered evident to me that the first nerve responds to a sufficiently powerful continuous current by the perception of such a peculiar smell. I shall presently have to refer to a pathological confirmation of this physiological fact.

The peculiar structure of the cavity of the nose is in entire accordance with the theory that there is one nerve for common sensation and another for the special sense of smell. We find there two channels, an upper, anterior, and smaller one, which serves for olfaction, and a lower, posterior, and larger one, solely intended for respiration; and the ordinary communication between these two channels may be cut off by that projection of the mucous membrane which Meyer has called the "agger nasi," and which under the action of different muscles may assume different positions.

The mucous membrane investing these two channels differs in essential particulars. That which covers the lower respiratory channel, and which should strictly be called the Schneiderian membrane, possesses ordinary epithelial cells, and shows no peculiar pigmentation. It does not receive any fibres from the first pair, but only from the fifth, which impart to it common sensation. The mucous membrane of the olfactory channel, on the other hand, has a peculiar yellow-brownish colour owing to the presence of pigmented cells, which are called sensorial or olfactory cells, and constitute a higher development of epithelial cells. Dr. Wm. Ogle in an able paper on Anosmia, which appeared in the Medical and Chirurgical Transactions for 1870, has justly laid stress on the importance of this pigment, the quantity of which appears to be in direct proportion to the keenness of smell, while its absence seems to coincide with loss of that function. More recent researches by Exner have shown that division of the olfactory nerve in frogs and rabbits causes the development of these pigmented cells to be arrested, so that about two months after the operation only common epithelial cells are to be met with. At the same time the cilia disappear, and the peripheral end of the nerve undergoes fatty degeneration.

In animals whose smell is particularly keen, the pigmented cells are much more abundant than in man, in whom the sense is rudimentary, and children whose smell is obtuse have less pigment than adults. This is the reason why children have no difficulty in taking nauseous medicines, such as castor oil.

No sensorial cells are to be found in the mucous membrane of the accessory cavities of the nose—viz., the antrum and the frontal and sphenoidal sinuses; and this affords *primâ facie* evidence that these cavities do not participate in smelling. Indeed, it is more rational to assume that they serve for lightening the weight of the skull, for heating the inspired air before it reaches the larynx, for giving a peculiar timbre to the voice, which in disease of these parts acquires a nasal resonance, and finally for keeping up a steady supply of mucus which serves to keep the nasal cavity properly moistened.

(*To be concluded.*)

NOTES ON THE PATHOGENY OF DIABETES.

BY RICHARD SCHMITZ, M.D., Neuenahr.

(*Communicated for the Author by* DAVID PAGE, M.D.)

IN the following communication I wish to give a brief account of four cases of this disorder, the history of which appears to me of particular interest, partly by reason of their rarity—these being the only cases I have met with amongst 520 diabetics coming under treatment within the last twelve years—and partly because of their presumable bearing upon the pathogeny of diabetes.

CASE 1.—Mrs. A——, who has suffered for the last three years from diabetes, came under my observation on July 7th, 1873. At this date the sugar present in the urine amounted to 2½ per cent., but after three weeks' treatment it had nearly disappeared.

Early on the morning of the day fixed for her departure from Neuenahr I was hurriedly sent for, when I found her in a drowsy condition, with sunken look, and a pulse of 120. She had been seized during the night with violent colic, quickly followed by the vomiting of green-coloured matters. On being questioned she declared that she was not aware of having eaten or drunk anything which could have brought about this attack. No evacuation of the bowels for two days. Temperature in rectum 37·4° C. (99·3° F.); tongue dry and furred; intense thirst and great weakness. An examination of the abdomen, which was not sensitive on pressure, elicited nothing abnormal. Respiration frequent, between 30 and 40, and deep. The pain, which the patient described as extremely violent and griping, had its seat in the upper part of the abdomen, and was of an intermittent character. She lay, as I have said, in a drowsy state, from which she was aroused by the sudden attacks of vomiting and pain. Although her whole appearance gave me the impression of intoxication, I was unable to find anything in the vomited matters to justify such an assumption. I accordingly confined my treatment to the internal and external application of ice in order to check the sickness. This proved unsuccessful, as also the administration of sedatives, which mitigated only the violence of the pain.

Next morning no change. No abdominal tenderness on pressure; no alteration in form; no dulness; temperature normal; pulse faster, 130; respiration 45, with very deep inspirations. The patient sank rapidly, and died towards noon, the vomiting having ceased about two hours previously. The urine passed an hour before death was found to be free from sugar. An autopsy was not permitted. As I learned afterwards, she had a few days before this eaten very large quantities of sugar and rich pastry.

CASE 2.—On the morning of the 15th July, 1875, I was called to M. L——, a girl of thirteen years of age. The child had been suffering from diabetes for some time, and had been, the parents informed me, about three weeks at Neuenahr. There had been some improvement, and the amount of sugar in the urine had become reduced. According to their statement she was a somewhat spoilt child, and had, especially of late, been guilty of frequent errors of diet in eating fruit and sweetmeats. This had not, however, had any bad effect upon her general health, and, until the previous day, she had been well and lively. She all at once complained of acute colicky pains, became sick and vomited frequently. There had been no vomiting for the last two hours, but the pain continued. There had been no motion of the bowels for three days. Vomited matters described to have been of a green colour. Urine passed in fair quantity, clear and free from sugar. This child, who was also lying in a drowsy condition, threw herself about from time to time with loud screams and groaning. Pulse 120 to 125; breathing hurried but not superficial, about fifty respirations a minute. Tongue dry, but not furred; intense thirst; strong fetor from the mouth; great weakness. The abdomen was a little contracted, and rather tender upon pressure. The periodic attacks of pain were, as in the previous case, localised in the upper part of the abdomen. As the idea occurred to me that the child may have partaken of something noxious, I requested the parents to preserve any matters which might be vomited, and prescribed cold enemata and castor oil. I saw the child again in the afternoon; her condition was precisely the same, but no vomiting. No motion of the bowels, in spite of repeated enemata and two doses of castor oil. At seven o'clock I was again summoned, when I found the patient screaming and in the most violent clonic and tonic spasms; eyes wide open and fixed, and the pupils strongly contracted and with very slight reaction. The answers of the child were indistinct an unconnected. Half an hour afterwards tracheal râles suddenly occurred and she died. This altogether peculiar and quickly fatal attack naturally aroused suspicions of poisoning, especially as the child had just before been in the hands of a quack doctor. It transpired, however, that such harmless remedies as peppermint only had been administered, and, moreover, the results of the judicial post-mortem made at Frankfort, whither the body had been meanwhile conveyed, gave no support to the suspicion of poisoning.

CASE 3.—M. P——, a healthy child of seven years of age, came under my treatment on the 15th August, 1879. Her mother told me that quite a year ago the child, who was exceedingly addicted to sweet things, had had repeated attacks of gastric catarrh. She had become much reduced, and latterly suffered much from thirst; these circumstances led to the detection of diabetes. The attacks of acute gastric catarrh still continued to recur from time to time, and the child then felt herself better only after a thorough evacuation of the bowels, on which account her mother was accustomed to give her a dose of castor oil whenever she began to be out of sorts. The urine contained only 1 per cent. of sugar and the subjective state of health was most satisfactory.

After she had been about a week at Neuenahr, during which time she had been placed upon not too strict a dietary, I was sent for one morning as another of her attacks of gastric catarrh had come on. I found in her case almost precisely the same symptoms as I have already described: great drowsiness, prostration, vomiting of green matters, very violent paroxysms of pain in the upper part of the abdomen, exactly in the region complained of by the other patients; abdomen not tender on pressure, but somewhat tumid. Pulse 120; respiration between 30 and 40; inspiration deep; temperature rather elevated, 38·5° C. (101·3° F.). Tongue dry and coated; strong fetor from the mouth. Urine free from sugar; no sugar or poisonous matters in the vomit. Constipation for last two days. A tablespoonful of castor oil was at once administered, and as this had not acted another in a couple of hours afterwards. An hour later, with remission of all symptoms, several very copious, extremely offensive, and almost black evacuations took place, which were repeated several times during the night and following day. In two days the child was again perfectly well. Curiously enough, eight days elapsed before traces of sugar again showed their presence in the urine.

Case 4.—Herr M——, twenty-eight years old, suffered from diabetes accompanied by considerable albuminuria (0·3 per cent.), and since the sugar had quickly disappeared under anti-diabetic treatment, I felt it advisable on account of the high percentage of albumen present to enjoin on him a less rigid dietary, and especially to allow him milk. The effect of this change was to reduce the albumen within three weeks to less than 0·1 per cent.; sugar, on the other hand, reappearing to the amount of 0·5 to 1·0 per cent. On the 26th July, 1880, Herr M—— was suddenly attacked with all those symptoms which have been already described. Several doses of castor oil brought about the same evacuations as in the preceding case, followed likewise in his case by complete recovery. No sugar and very little albumen were present in the urine.

Putting together, now, the symptoms common to these four cases, we have in the first place violent paroxysmal pain localised in the upper part of the abdomen; frequent vomiting of green-coloured matters; exceedingly obstinate constipation; head affection; somnolence (only in the second case were the symptoms of depression succeeded by others indicative of cerebral irritation); great prostration; small frequent pulse; very rapid breathing with remarkably deep inspiration, dry tongue, intense thirst, and not essentially elevated temperature. In all sugar was notably absent from the urine, notwithstanding the fact that sugar-containing food had been taken beforehand. There was also neither increased tenderness of the abdomen to pressure, nor significant distension or dulness. The hepatic dulness had not disappeared.

With regard to these general symptoms, acute peritonitis may be put out of the question; and so also any renal affection, for in three of the patients the urine afforded no evidence of anything of the kind, whilst in the fourth case the albumen had actually diminished in quantity. These symptoms, too, would also tend to exclude the possibility of a gastric or intestinal catarrh, such as one is accustomed to see following upon the immoderate ingestion of indigestible food, but give support to the view that only an extremely poisonous substance or material, affecting chiefly the intestinal tract, could have been competent for their production. Inasmuch as no poisonous substance had been actually taken by any one of the patients, such could have only been formed in the intestine itself; moreover, in both of the last two cases recovery and improvement at once followed upon abundant evacuations of extremely offensive and almost black quantities of excremental matters, whilst in the case of the other two which ended fatally, an ordinary movement of the bowels proved impossible.

In similar cases, therefore, I would strongly advice a full dose of castor oil not to be delayed, even should no previous constipation have existed, and that every effort be made to empty the bowels as thoroughly and as quickly as possible. Now, I believe that the poison whose source must be referred to the intestine stands in some kind of relation to the diabetes—i.e., the sugar; for whilst all four patients were diabetics, yet during the attack the sugar entirely disappeared from the urine, and this in spite of well authenticated errors of diet having in each instance been committed. It is not too far-fetched to assume that the ingested sugar had undergone transformation in the intestine, and produced the poison. If such be the case, then, my views with regard to the pathogenesis of diabetes have anew received essential confirmation. Seven years ago I published the history of a case of diabetes in a child of four years of age, whose mother was also a diabetic.[1] At the desire of the latter I had for some time made continued examinations of the urine, always finding it free from sugar. The child was suddenly taken ill, with symptoms of gastric fever. The urine, which a few days before had been free from sugar, was now found to contain nearly 6 per cent., this amount, however, completely disappearing under the anti-diabetic diet in the course of a fortnight. The child quickly recovered, and is now living.

This case, as also the statements of various diabetic patients who had suffered from attacks of gastric fever, and in whom only subsequently the symptoms of diabetes developed themselves, suggested to my mind the possibility of a connexion existing between the two disorders and of the seat of diabetes in many cases being found in the upper part of the alimentary tract. I asked myself the question what, under normal circumstances, becomes of the sugar often ingested in large quantity, seeing that very little of it is found again in the chyle or the blood of the portal vein? It must be transformed somewhere, and may not this transformation be effected in the duodenum by the agency of the alkaline pancreatic juice? If, then, the digestion of sugar does take place in this way, and it should happen that the pancreatic secretion was insufficient from disease of the pancreas itself, from the disturbing and inhibitory influence upon the nerves controlling the secreting function of pathological events, or from the constant ingestion of sugar in too large amount, a greater or less quantity of sugar which has escaped transformation must accumulate in the intestine.

As it has been conclusively shown that the intestinal mucous surfaces absorb sugar, mellituria quickly following upon the injection of sugar by the rectum, the absorption of sugar by the small intestine and rest of the tract in much larger proportion and far more easily must ensue. But besides being absorbed, the sugar thus accumulated in the bowel may, and this is more to the purpose, easily undergo fermentation and decomposition. To this fermentation and decomposition of the sugar are due the gastric fever of the child, those gastric symptoms previously in question, the extremely profuse diarrhœas so frequent in diabetics, and lastly, the four attacks of illness above described. The only difference in regard to these last is that the change had proceeded so far as to develop some intensely poisonous product.

I have already mentioned the peculiar incident of the disappearance of the sugar entirely from the urine of these four patients, and I may now state, in addition, that after the above described attacks of diarrhœa in diabetics I have always found upon examination of the urine a marked diminution, or even total disappearance, of the sugar. So far as I am aware, a chemical examination of the diarrhœtic discharges has not hitherto been made whereby one might be enabled to decide whether that fact is to be ascribed to the expulsion of the sugar with the other contents of the intestine, or whether these discharges contain only the products of its decomposition. Be this as it may, the fact itself remains certain, and speaks in favour of the views I have adduced, in further support of which is the circumstance that there is no better treatment for diabetes than a diet practically free from sugar and amylaceous ingredients; for here the amount and quality of the pancreatic juice are sufficient to meet the trifling quantity of sugar present. The practitioner who, like myself, is in the position of having a large number of diabetics under treatment at the same time (in the summer of last year my *clientèle* included 110 such patients), may easily observe how exceedingly diversified is the immunity towards sugar in the case of individual patients—in other words, how far the quantity and quality of the pancreatic juice suffices for the satisfactory transformation of the sugar in different cases. Thus one patient will tolerate 20 grms. of brown bread (two-thirds of an ounce), but not even 10 grms. of white bread (a third of an ounce); another can eat both with impunity, and the same quantities of lentils and peas besides; a third even rice and potatoes in even larger amount, while another cannot take any of these whatsoever—indeed, not even some starchy gluten bread or leafy vegetables which have not been deprived of the stalks with every possible care. I may remark that I always seek to prescribe for each patient a special diet suited to the individual.

The existence of cases of diabetes where under a so-called purely animal diet the sugar is averred to be formed from the albuminoids, I should be inclined to call in question; for how is it possible to prepare a dietary which shall be absolutely free from sugar? Do not flesh and the yelk of egg, wine, even the most acid, all contain sugar? and with regard to vegetables, do not the stalks and ribs of the salad and leafy herbs also contain some sugar? In short, with the exception of cheese and sour milk, there is scarcely anything to be found which does not in some proportion or another number sugar of some kind amongst its constituents. If, in spite of a diet of flesh, fish, eggs, herbaceous vegetables, and red wine the sugar has not disappeared, then depend upon it that either the pancreatic juice is incompetent to accomplish the transformation of these small quantities of sugar, or that the patient has not strictly adhered to his diet; and the latter will prove to be most frequently the case.

How often I have had occasion in my practice to observe that patients, in spite of the most solemn promises, have clandestinely eaten forbidden articles of diet, even of saccharine articles and sugar itself, to large excess! How many cases can I recall in which the sugar in the urine, after having quickly diminished in amount to a small percentage, all at once began to increase rather than to decline! And how many patients, apparently sensible and intelligent, solemnly assured me that they had eaten nothing save what had been allowed, and then, by chance, it came to my knowledge that this one had eaten a couple of pounds of cherries, that one half a pudding, and so on, persistently committing altogether the most grave errors of diet! Once a diabetic patient assured me on his word of honour that he had most conscientiously adhered to the diet which I had prescribed, and his wife complained to me with tears that he had threatened her with violence if she did not supply him with plenty of bread and sugar! It is, indeed, quite a peculiarity what an often unconquerable desire diabetic patients have for sugar and saccharine articles of food.

---

[1] Berliner klinische Wochenschrift, 1873, No. 19.

I need hardly say that my views apply only to true diabetes—that disease in which the ingested sugar, instead of undergoing the normal transformation, passes into the blood and fluids of the body. To those merely casual attacks of mellituria which owe their origin to the most diverse conditions no reference is necessary.

San Remo.

CASE OF

ACUTE PHTHISIS TREATED BY THE CONTINUOUS TOPICAL MEDICATION OF THE LUNGS.

By G. HUNTER MACKENZIE, M.D.,

LECTURER ON LARYNGOLOGY, PHYSICIAN FOR THROAT DISEASES TO THE WESTERN DISPENSARY, EDINBURGH.

In a former communication (The Lancet, Nov. 27th, 1880) I directed attention to the system of continuous topical medication of the lungs in phthisis, and showed how it might be successfully carried out by means of a respirator[1] specially constructed for the purpose. I now wish to record in detail a case of acute phthisis which has been treated by this method with satisfactory results.

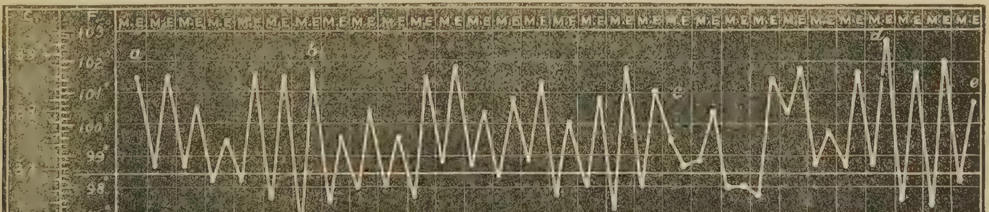
A. B——, male, aged eighteen, a lithographer in Edinburgh, consulted me in July, 1879, complaining of general weakness, cough, and emaciation. Two brothers had died of phthisis, and there was a history of the same disease in his maternal relations. The patient had not suffered from any previous complaint. He had not lately had a cold, and he could assign no particular cause for his ill health. On examination, the pulse was quick and small (110); temperature 100·5°; respiration slightly hurried. The mouth and tongue were rather dry, the latter slightly furred. Beyond a slight roughening of the respiratory sounds, and prolonged expiration, there was nothing to be detected in the lungs. He was ordered cod-liver oil, with hypophosphites, abundance of milk, and residence in the country, for which he soon left. In October I was called to see him, and during that and the succeeding month he became rapidly worse. The fever increased, an evening temperature of 103° being recorded, with a correspondingly quick pulse, shallow and hurried respiration, lips coated with sordes, thirst, and lividity of the extremities. The lungs now gave undoubted signs of disease. There was marked dulness over the upper third of the left lung anteriorly, with copious fine crepitation, racking cough, occasional bloody sputum, severe night sweats, and loss of hair. The general weakness increased to such an extent that the patient latterly could scarcely leave his bed without assistance. The treatment pursued in the first instance embraced the continued administration of cod-liver oil and hypophosphites, quinine and digitalis, maltine, &c., with the usual regulations as to diet and hygiene. At this time I had not the same facilities for making continuous observations as latterly, but there was no disputing the fact that the disease, in spite of the above and similar treatment, continued to make rapid and alarming headway. Under these circumstances, on November, 26th 1879, I commenced the system of topical medication. Marked improvement of the various symptoms soon followed. The subjoined charts indicate the thermometric range (the most precise gauge of the progress of phthisis) from January 27th to July 12th, 1880, with one or two intervals, when the observations, from some cause or other, were not made or recorded. During the period not embraced in the charts—Nov. 26th, 1879, to Jan. 27th, 1880—the patient also steadily, though slowly, improved. (See Chart I.)

The general results of the treatment so far were: (1) slight fall of temperature; (2) great diminution of the cough, with complete cessation of the muco-purulent sputum; (3) marked improvement in the appetite and general strength; (4) gradual abolition of the night sweats; (5) improvement in the physical condition of the lungs. To assist in determining the relationship between the particular method of treatment employed and the improvement in the patient's condition, I now discontinued the creasote and carbolic inhalations, with the following results. (See Chart II.)

Charts showing the Morning and Evening Temperature in a Case of Acute Tubercular Phthisis.

Chart I.—*Using Respirator.*

(The use of the respirator was commenced on November 26th, 1879, but the under-noted observations only date from January 27th, 1880.)



a. Jan. 27th, 1880.—Using respirator charged with pure creasote.
b. Feb. 2nd.—Using respirator charged with three parts of carbolic acid to one of creasote.
c Feb. 15th.—Phenol in urine (Falconer King).
d. Feb. 22nd.—Commenced creasote pill, containing one drop, after dinner.
e. Feb. 25th.—Discontinued use of respirator and creasote pill. No albumen in urine.

Without the use of the respirator the patient decidedly relapsed. As indicated on Chart II., the temperature, as a rule, was higher, the cough and sputum returned, there was a renewed tendency to nocturnal sweating, and the patient expressed himself as not feeling nearly so well as when wearing the respirator. At his own desire he resumed the inhalations, and again most marked improvement followed, as indicated on Chart III.

The further history of this case is of interest. During the late severe winter the patient went about rather freely, and, contrary to my advice, abandoned altogether the creasote inhalations. The result was that about the beginning of the year he had a relapse, with a return of the cough, night sweats, and other symptoms, but not to the same extent as formerly. He now, of his own accord, resumed the use of the respirator, and precisely the same results as on the two former occasions followed. When I had an opportunity of examining him, on March 8th last, the evening temperature was 98·9°; there was no cough, expectoration, or night sweating; the appetite was good, and the patient felt

---

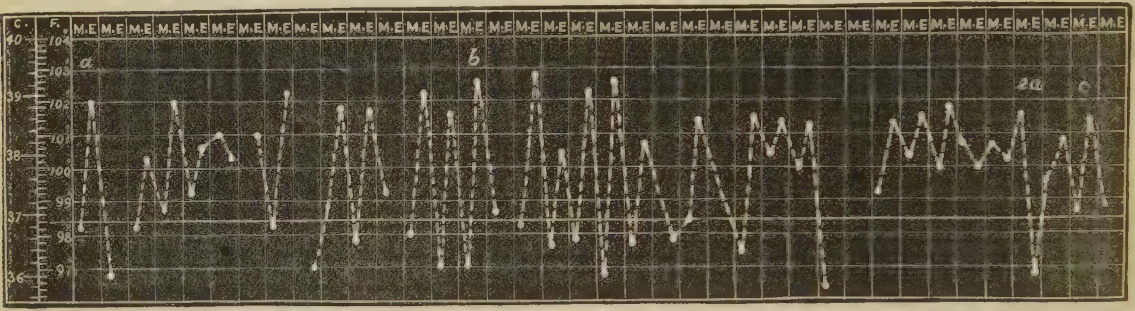
[1] The respirator as used by me is made by Mr. Gardner, South Bridge, Edinburgh.

"very well." There was a scarcely appreciable dulness at the left apex anteriorly, with prolonged expiration at both apices, but no moist sounds were audible. He had slightly increased in weight. The patient was not by any means "the picture of perfect health," but he had a very different appearance from what he presented before commencing the use of the respirator.

Remarks.—There can be no doubt whatever that the success in this case was owing to the particular method of treatment employed—viz., causing the patient to respire as continuously as possible an "antiseptic" atmosphere. The result obtained would appear to bear out the experiments of Schüller of Greifswald, who found that animals rendered artificially tuberculous were cured by being made to inhale creasote water *for lengthened periods.* (The italics are mine.) Intermittent spraying or inhaling does not produce the same result. In order to ensure success the application to the lungs must be made *continuously.* For this purpose I have used various volatile antiseptics, such as creasote, carbolic acid, and thymol. The latter I have now discarded as being too irritating and inefficient. Carbolic acid seems to be absorbed, for it has been detected freely in the urine, in this and other cases where it was inhaled, by my friend and colleague Mr. Falconer King, lecturer on chemistry. Mr. King has been unable to find any trace of creasote in the urinary excretion after the use of creasote for several consecutive days. As absorption of the particular drug employed is not necessary, and therefore not to be desired, I now use creasote only, either pure or dissolved in one to three parts of rectified spirit. Whether the success so far attained is due to the antidotal action of creasote and carbolic acid on a specific tubercular neoplasm, or to their action as preventives of septic poisoning from the local centres in the lungs, it is certain that their continuous, steady use in the manner just described has a decidedly curative action in acute phthisis, and is therefore worthy of an extended trial.

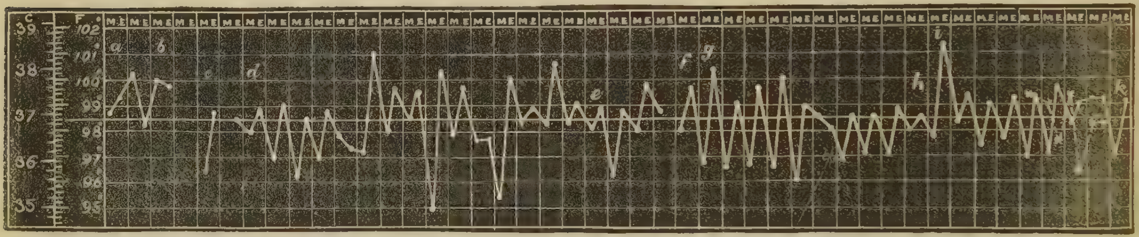
Edinburgh.

CHART II.—*Respirator not used.*



a. Feb. 26th, 1880.—Discontinued use of respirator.
b. March 11th.—Cough increased. Appetite impaired. Night sweats not returned. Occasionally feels very hot.
c. April 2nd.—General condition deteriorating. Feels himself not so well as formerly. Night sweats occasionally present.

CHART III.—*Using Respirator.*



a. April 24th, 1880.—Commenced use of respirator charged with pure creasote, fifteen days previously.
b. April 26th.—Commenced to take half an ounce of cod-liver oil night and morning.
c. June 1st.—Cough and night sweats absent. Hair not coming out. Appetite very good. Looking much better.
d. June 3rd.—No creasote or albumen in urine (Falconer King). All subjective febrile symptoms disappeared. Slight diarrhœa.
e. June 19th.—Took walk of four miles without difficulty.
f. June 23rd.—Commenced maltine, two drachms thrice daily.
g. June 24th.—No albumen or phenol in urine (Falconer King).
h. July 3rd.—Dropped maltine.
i. July 4th.—No apparent cause for increase in temperature.
k. July 12th.—Discontinued use of respirator. Patient feels quite well.
* Indicates own temperature taken at same time, and under similar conditions as patient.
Aug. 13th.—Patient went to the Highlands, apparently well.
Sept. 1st.—Temperature 99° (evening).
March 8th, 1881.—Temperature 98·9° (evening).

RECOVERY FROM APPARENT DEATH UNDER CHLOROFORM.

BY WILLIAM KORTRIGHT BROCK, M.R.C.S.,
LATE MEDICAL OFFICER TO THE FULHAM UNION INFIRMARY.

THE subject of death from chloroform having lately been made prominent in the pages of THE LANCET, the following record will, I think, be read with more than usual interest at present.

J. M——, aged twenty-four, an inmate of the above infirmary, about three years ago received an injury to the spine by falling from a scaffold thirty-five feet high, his back coming across a pole, whence he slipped on to a heap of bricks. The exact nature of the lesion received did not appear. He was taken, according to his own statement, to St. George's Hospital, whence, after remaining there seven months, he was discharged as incurable, and received into the Fulham Union, having lost all sensation and voluntary motion below the waist.

The details of this case will be reproduced more fully on a future occasion as one of a series illustrative of the effects of actual cautery in treating certain forms of paralysis. Suffice it therefore now to say that the patient came under my notice in February, 1879, when I took office at the infirmary, and that at first I accepted the verdict passed on him at St. George's. But reading a paper by the late Surgeon Major Porter on the use of actual cautery in a somewhat similar case, I was induced to carefully examine him, with the view of determining whether it were worth while to attempt the like treatment. He proved to be an exceedingly intelligent, happy-minded fellow, and urged that even the remotest chance of improving him should not be left untried.

The following was his description at that period :—A small, spare, fair, boyish-looking man lying on his back, with a sheet tied tightly across his knees to prevent them flying up to his chin, and pads between the knees and ankles, which were ulcerated from pressure ; his fixed condition being one of violent permanent spasm of the flexor and adductor muscles of the lower limbs, with paralysis of the bladder, and total loss of feeling below the level of a bony growth, as large as an egg, engaging the fifth and sixth dorsal vertebræ. There was no angular curvature or chest deformity. His general health was excellent, appetite good, lungs and heart sound.

Yielding to his importunity, though with but faint hope of benefiting him, chloroform was administered, and two eschars made, an inch wide and six inches long, on each side of the spinal swelling, the instrument used being an ordinary iron for spreading plaster, heated ; these were connected by arrow-headed markings. The issues were kept open about three weeks with poultice and savine ointment, after which they healed up, apparently without having produced appreciable effect, though J. M——, who used to test his own sensibility with a needle, declared he could "feel lower down than before," and insisted on the operation being repeated. This was done with such palpable improvement that it was re-performed four times at various intervals. At length he could feel the prick of a needle keenly at the hips, and more slightly at the legs. Erections and voluntary micturition were re-established, and he could extend, flex, or otherwise move his legs at will, though still with great effort. In each operation I had hitherto had the aid of two medical friends, Mr. Hildyard Rogers of Shepherd's Bush, and Dr. McSwinney of Brook Green. In June last, in compliance with his urgent entreaty, I made arrangements for repeating the operation for the fifth time, but at the last moment both my friends were detained elsewhere. It was, therefore, postponed till the following day, when again I found myself alone. As the man had twice been kept without his dinner, and was greatly disappointed, at his particular request I consented to proceed single-handed ; for we had neither assistant, dispenser, operation room, nor any of the appliances of a well-ordered establishment afforded by the guardians (even midwifery instruments being refused me), though having from 350 to 400 patients on the average. Yet, under these disadvantages, operations were not of rare occurrence ; within a short period the closing a vesico-vaginal fistula, amputation of the leg, excision of the breast, removal of half of the inferior maxilla and other matters having taken place successfully.

In this case I had no misgivings; the man had taken chloroform already four times, requiring an unusually large quantity to produce anæsthesia, and recovering from its influence very rapidly. Besides, my experiences of the exhibition of the drug could be counted by the thousands, extending back to the days of the Crimea, and hitherto without a shadow of mishap. This time he took the anæsthetic better than ever, less than two and a half drachms proving sufficient. The same procedure as before was gone through. Rolled over on to his stomach, with a pillow beneath it to throw up the back, the head nurse, a most careful, trustworthy person, took charge of the face to keep the mouth disengaged from the bolster, while I applied the iron, assisted by two or three other patients. A piece of oiled lint was then laid on the spot, and J. M—— placed on his back, his pulse and breathing being then both good. I turned from the bed and walked to the stove, a distance of about fifteen feet, to put down the iron, when a cry from the nurse brought me quickly back. Respiration and heart action had ceased suddenly and completely. Having first ascertained that the mouth and rima glottidis were free from mucus, the head was allowed to hang down over the edge of the bed for a few seconds ; then lifting the body on to the floor, a needle and thread snatched from a bystander were passed through the tongue, which the nurse held forward, while artificial respiration was vigorously carried on by compressing the chest walls; at the same time cold water was plentifully thrown on the body and ammonia applied to the nostrils. At the end of six minutes, when all seemed unavailing, I stopped for a moment to look at the patient. There was a something in his blue appearance that impressed me with the idea that actual death had not yet occurred, and putting my ear to the heart, I fancied a sound like a distant thrill or murmur could be detected. Artificial respiration was resumed, and in a few seconds more the heart's action was very distinct, but there was no attempt at breathing. Hard slaps, cold water dashed on face and chest, blowing violently down the fauces, were all tried in vain. It was singular to note the apparently dead body show its perception of injury by slightly moving the hand in the direction of the part struck. After the lapse of eight minutes a long and deep inspiration took place, then at an interval of eight or ten seconds another, and then others more frequently.

The galvanic battery having refused to act the day before, it was presumed to be out of order, and had not been brought into the ward ; but a thoughtful patient, ignorant of this, had fetched it, and having by this time fixed the wires, put one pole into my hand, which I placed on the epigastrium, directing him to apply the other to the nape of the neck. This he did so rapidly, before I had time to alter the regulator, that the whole current from fifty cells was transmitted, the machine happening to resume its proper action. J. M—— sprang up into a semi-sitting posture, and exclaimed, "Oh, dear! what are you doing of?" He was got back into bed just as the Local Government Board inspector, who was making his official visit, entered the ward. The time that elapsed from the moment of apparent death to his speaking was just ten minutes. Soon after the above narrated occurrence, I resigned the post of medical officer to the infirmary, and consequently lost sight of J. M——, but have heard that he has since gone out in a wheel-chair, sitting upright without difficulty. I believe a pea issue, steadily kept up for a period of two months, would have perfected his recovery, or at least enabled him to walk.

Clifton.

NOTE ON ABSENCE OF BEER IN AN ASYLUM DIETARY.

By J. A. CAMPBELL, M.D., F.R.S.E.,
MEDICAL SUPERINTENDENT, GARLANDS ASYLUM, CARLISLE.

THE subject of the use of beer in the dietaries of public institutions, for patients, attendants, nurses, and servants, has for the last few years much exercised the minds both of the lay rulers of such institutions and of the medical heads, and a diversity of opinion still exists. The use of stimulants in sickness is also much discussed, and affords considerable scope for variety of opinion and practice.

The asylum which I at present superintend was at one time, I believe, the only English asylum in which beer did not form an article of ordinary diet for patients, attendants, or resident medical officers, and as the asylum has now been in existence since January, 1862, its general results may be fairly taken for purposes of comparison. The Committee of Visitors, when the asylum was opened, were of opinion that in many respects it was highly advisable that the diet-scale, and also the hours for meals, should accord to a certain extent with what was in force in the district from which the patients were drawn, and hitherto they, or their successors in office, have seen no reason to alter the opinion which was wisely come to at a period when, in the belief of many, it was wrong. Beer does not form a usual part of the diet of the working-class in these two counties, and their hours for meals would by many be thought barbarously early.

I have for several years had so many inquiries into the matter of diet, and the absence of beer in it, and as to the effects of this want of beer in reducing the health, in evilly influencing recovery, &c.—some of these inquiries have been so full and particular as to percentages of recoveries and deaths, the cost of stimulants as medicinal treatment, and the cost of medicines,—that I have drawn up the following tables, which show the main points that can be of any value to other institutions ; while I avoid all comparison which might be invidious, and which, if required, may easily be made by those who wish to enter on the subject.

As during the first year of the existence of this asylum the reception of chronic patients much influenced the results, and also as there was no report printed, I simply give the results contained in the ten yearly reports drawn up and issued by my predecessor, Dr. Clouston, and those from my own reports for the last eight years. I give in a tabular form the percentage of recoveries on admission, the percentage of deaths on the average numbers resident, the cost of stimulants (used medicinally) per head, and also the cost for medicine during these two periods.

	Years.	Percentage of Recoveries on Admissions.			Percentage of Deaths on Average Nos. Resident.			Wine, Spirits, and Porter.	Surgery and Dispensary.
	From Jan. 1st to Dec. 3rd.	Males.	Females.	Total.	Males.	Females.	Total.	s. d. 16th	s. d. 16th
1st Period of 10 Years.	1863	30·6	18·4	25·0	4·3	6·4	5·2	0 1 12	0 0 7
	1864	30·7	38·0	34·0	12·0	12·0	12·0	0 1 14	0 0 13
	1865	30·0	44·0	38·6	3·8	9·4	6·2	0 1 14	0 0 13
	1866	15·0	38 0	25·7	5·2	2·8	4·0	0 1 13	0 0 10
	1867	27·1	34·2	29·9	12·8	6·9	10·3	0 2 10	0 1 1
	1868	36·7	38·3	37·5	7·4	7·7	7·6	0 2 12	0 1 8
	1869	41·2	37·5	39·1	8·9	6·3	7·7	0 1 14	0 1 2
	1870	47·9	44·0	46·2	5·0	6·5	5·7	0 2 7	0 1 0
	1871	43·8	56·0	48·5	11 0	8·6	9·9	0 2 9	0 1 9
	1872	51·1	48·0	49·5	8·0	5·8	7·0	0 2 10	0 1 3

The percentage of recoveries for this period averaged 39; the percentage of deaths on the average numbers resident was 7·6. During this period one pint of milk was given to the men and three-quarters of a pint to the women for six days of the week at dinner. I had the amount of milk reduced to half a pint for each sex, and only gave it three days in the week at dinner, as I thought it did not suit the dinners with fat meat or warm gravy, but the dietary has remained unchanged as regards the amount of butcher-meat.

	Years.	Percentage of Recoveries on Admissions.			Percentage of Deaths on Average Nos. Resident.			Wine, Spirits, and Porter.	Surgery and Dispensary.
	From Jan. 1st to Dec. 31st.	Males.	Females.	Total.	Males.	Females.	Total.	s. d. 16th	s. d. 16th
2nd Period of 8 Years.	1873	37·3	48·3	43·2	5·3	6·2	5·7	0 2 5	0 1 4
	1874	40·3	54·1	46·6	11·5	7·7	9·8	0 3 7	0 1 9
	1875	38·1	43·1	40·3	6·9	6·2	6·6	0 2 12	0 1 0
	1876	43·3	45·0	44·2	15·5	5·9	10·9	0 1 15	0 1 4
	1877	49·0	51·0	50·0	7·7	4·2	6·0	0 1 14	0 1 2
	1878	59·5	59·7	59·5	7·2	8·6	7·8	0 1 6	0 0 14
	1879	35·4	64·0	51·7	8·2	5·5	7·1	0 1 4	0 1 0
	1880	30·4	50·0	39·5	9·8	9·3	9·5	0 1 3	0 1 3

The yearly recovery rate during the eight years averages 47 per cent.; the average percentage of deaths on the numbers resident is 7·9. As the general health has been good, and as in the vast majority of cases the patients admitted have been found to gain in weight after admission (careful weight records being kept), I think the ·3 per cent. of rise in mortality may easily have been caused by the action of the Government grant of 4*s.* per week, for lately we certainly have had more old cases sent in than used to be sent some years ago.

I believe I am correct in saying that in most if not all of the Scottish public asylums no other beverage than cold water is given at dinner. I am at present considering the question of doing away with the small quantity of milk which is given here on three days in the week. The attendants and officials have seemed to keep in good and robust health with water as their beverage.

Carlisle.

BELFAST HOSPITAL FOR SICK CHILDREN.—The gold medal offered annually for competition to the students attending the hospital clinique has lately been awarded to Mr. Thomas Sinclair for distinguished answering in an examination on the diseases of infancy and childhood.

NOTES OF A

CASE OF EPILEPTOID HYSTERIA WITH CATALEPTIC SYMPTOMS.[1]

BY J. Y. TOTHERICK, M.D. ST. AND., M.R.C.P. EDIN.,
PHYSICIAN TO THE WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

ON July 2nd, 1880, Mary M—— came to the out-patient department of our hospital complaining of "fits," great difficulty in walking, choking sensations, and an enormously distended abdomen. I prescribed bromide of potassium and valerian, with some aperient. She reappeared on the 9th with every symptom much aggravated, being unable to stand, her limbs rigidly extended, the "globus" greatly alarming her, and the abdomen even more distended. In addition I found that her lower limbs and abdomen were quite anæsthetic. She was admitted as an in-patient, and the following notes were taken by our house-physician, Dr. Mortimer.

The patient is a stout, well-built, well-nourished girl, aged nineteen, with placid composed expression, smooth, fair complexion, fair hair, pale-blue eyes, long lashes, and well-cut features. Her family history is remarkably good. She states that since the appearance of the catamenia (which have never been regular), three years ago, she has never been healthy, and during the last three years she has had "fits," slight at first, but during the last twelve months of a violent character and frequent (as many often as five or six a day). During this period she has been under several doctors "for a bloated swelling in the bowels," one of them telling her she had a "tumour." She has been very hard-worked as a general servant, acting as nurse to her mistress, who died; then her master falling ill she nursed him also, apparently with much devotion. She felt frequently giddy, and had violent fits, occasionally lasting two or three hours, and for a short time after each lost the use of her arms, but never of her legs or body, until a month ago, when stiffness came on in the legs, with total loss of sensation.

On admission the patient's condition was as follows:—

Nervous system: Mental faculties acute; answers questions rapidly, intelligently, and with goodwill; much tendency to sleep; complains of giddiness.—Cranial nerves normal, except very marked loss of sensation in all the branches of the fifth pair; conjunctivæ can be pricked without causing a wink.—Spinal cord and nerves: No spontaneous pain in back, but tenderness over third cervical spine on pressure, and also in mid-dorsal and sacral regions. Complete loss of sensation to pain over whole surface—limbs, trunk, head, and neck. Pins can be inserted deeply into the muscles on either side without producing the slightest pain or reflex action, but tactile sensation seems normal in fingers.—Motor powers: Normal in arms; complete loss of voluntary power in both legs, which are kept in a state of rigid extension, even to the toe ends; no tremors; no spasm. Reflexes—plantar, patellar, abdominal, and epigastric—absent. Bladder centres apparently normal.—Electrical reactions: Sensation to faradaic current entirely lost in arms and legs; muscular irritability to same current much diminished. Galvanic current not used, because during the use of the faradaic current the patient appeared to pass into a semi-cataleptic state; heavy, drowsy, sighing; with limbs firmly fixed, and maintained in whatever position they were placed. There was for a short time complete loss of consciousness. There was no acceleration of pulse during observation. Chloroform being administered to complete anæsthesia, the immense abdominal distension entirely disappeared, as also did the rigidity of the legs. On recovering from the anæsthetic, but whilst still deeply under its influence, the plantar reflex reappeared, and the conjunctivæ also seemed more sensitive. The patient, however, very speedily relapsed, even while still under the influence of the anæsthetic. Metallo-therapeutic tests—viz., gold and silver coins—were applied alternately to both legs without apparently the slightest result.—Organs of circulation: Pulse 80, full, firm, and regular; nothing else noteworthy. Organs of respiration normal. Organs of abdominal and digestive functions also normal. Slight polyuria and albuminuria; no dysuria; deep pressure over both ovarian regions produced no result. These investigations occupied a period of three days.

---

[1] Read at the Wolverhampton District Medical Society on Tuesday, Dec. 7th, 1880.

July 13th.—The patient *in statu quo*. She had a slight fit of an hysterical character on the first night. Her bowels had been well relieved by pills of aloes and iron. As she lay on a protected bed, her legs were exposed from the knee, and a drop of cold water was allowed to fall on to each at the rate of about eight per minute from an apparatus arranged at a height of about six feet from the bed, for twelve hours.

14th. — The dropping water has caused "a glowing feeling" in the back and arms, and tingling in the spine. She slept well after it was discontinued, and the cutaneous sensation is much improved this morning to level of knees, but still there is some slight general anæsthesia. The patient can rise in bed with more facility, and some slight voluntary motion was observed in the left leg. Water-dropping resumed at 12.30.

15th.—There is very marked increase both in faradaic sensibility and irritability this morning; in the arms it is almost normal, most deficient below knees.

16th.—Marked improvement of voluntary motion in left leg; ankle can be flexed and extended to a moderate extent. Sensation completely returned; slight increase in right leg over upper third. Spasmodic twitchings of muscles of right thigh. Gold test again tried with no effect. Water-dropping resumed on right leg. Blisters, which had been applied to tender points in spine yesterday, had risen well.

17th.—The patient could walk a few steps this morning after some "encouragement"; water applied again to both feet.

19th.—The patient walks well to-day; the phantom tumour, which had almost disappeared, has slightly returned.

20th.—The phantom tumour much more marked, with some abdominal pain, apparently muscular. Water to be dropped on to both recti abdominis for twelve hours.

24th.—No improvement; and on examination sensation—tactile and to pain—quite absent over parts supplied by dorsal nerves from about the sixth to the eleventh.

August 1st.—The patient has been walking in the grounds since last note, and appears quite well, except for the persistence of the phantom tumour and the anæsthesia. An ice-bag was applied to abdomen, but with no effect. Yesterday two flat corks, two inches and a half in diameter, were pierced with numerous pins, the points of which were allowed to project to the extent of a quarter of an inch. The prickly surface was applied to the skin of the abdomen on each side, and strapped on tightly. Notwithstanding these instruments of torture, the patient slept well all night, and her condition this morning is unaltered. Situation of pins very red, but corks again applied.

10th. — Anæsthesia has extended rather higher in the trunk; sensation both to touch and pain diminished from Poupart's ligament to an inch below the clavicle; liquor epispasticus applied to dorsal and lumbar regions with no beneficial result.

17th.—Faradaic current applied to both recti daily for three minutes, without result.

20th.—A large-sized galvanic belt, steeped in dilute acetic acid, was applied below the umbilicus to the bare skin for several days. This produced no effect save severe ulceration of the skin, which was not, however, felt. To avoid the ulceration a piece of lint, kept wet with the vinegar, was interposed between the belt and the skin, and it was now applied above the umbilicus. Two days after this application the abdomen was felt to be softer; on the fourth day the swelling had much diminished, on the fifth day it had entirely gone, and a fortnight afterwards the girl went home in the most perfect health.

I shall have very few remarks to make respecting this most singular and interesting case. One might heartily wish that the word hysteria were banished from our medical language—and indeed, so far as its etymological signification is concerned, from our medical thoughts. The uterus, as an important organ of the body during its physiological activity, certainly suffers with the rest; and often, no doubt, its disordered functions react on the nervous system, giving special characters to nervous disease; but I think to call such a case as the one I have related hystero-epilepsy is an abuse of terms. Here was a perfectly healthy, well-made girl, with her strength worked down by hard service and want of fresh air, becoming anæmic and "irregular" in consequence. The pressure upon the nervous system being continued and the hygienic conditions worse, the nervous balance becomes lost, and irregular discharges of nervous force, the so-called fits, ensue. No efficient means being taken to restore the equilibrium, the occasional clonic spasms become in the abdominal muscles and in those of the legs tonic, whilst clonic spasm still invades the muscles of the larynx. At the same time sensation is lost, general anæsthesia occurs, the ordinary lines of communication between the centres of conscious sensation and the distribution of the sensory nerves are blocked. There is nothing, surely, directly attributable to uterine causation in all this. Is it not one of a class of cases in which hysteria is used rather as a confession of ignorance than as a rational pathology? I have, however, no better pathological theory to offer further than what I have said as to the probability of its being a disease of exhaustion in a somewhat weakly balanced nervous organisation.

The treatment I adopted will almost explain itself. I had a patient with considerable intelligence evidently extremely anxious to get well. There was nothing radically wrong with the brain functionally or organically. There were no symptoms of uterine disease or of ovarian irritation. My object was to re-establish as quickly as possible the channel of communication between the nervous centres and the periphery, and I had all the senses except sensation to help me, and also the imagination. The readiest means which suggested itself was a modification of the old Inquisition torture, and it more than satisfied my expectations. The abdominal distension, which had been the longest symptom in duration, was the last to yield, but I believe it yielded eventually rather to the physical effects of the battery than to the curative power of the electricity, as we well know is the fact with certain analogous cases of aphonia. However, whatever the cause of the cure, it was effectual and complete, and the girl was restored to an active and useful life, which I believe she still continues to lead.

Wolverhampton.

FOREIGN BODIES IN THE AIR-PASSAGES.

BY E. S. STEVENSON, L.R.C.P., M.R.C.S., &c.

THE following two cases are interesting inasmuch as they illustrate the origin of some obscure lung diseases. The notes are taken from my case-book and abbreviated.

CASE 1.—In June, 1878, I was consulted by F. A——, a coloured man, complaining of a bad cough. F. A——, aged forty-five, has been a hard drinker, and has led a life of constant exposure. He has had the cough for three months, gets no rest from it; it is constant, and worries him much. It is harsh and dry, and he does not spit with it. On examination the chest presents no abnormal physical signs. Two months afterwards he called again, the cough as bad as ever; the drugs which he has taken to allay it have had little or no effect. He expectorates now a muco-purulent sputum, and indicates a spot to the left of the manubrium sterni where he feels a constant dull pain, increased by the act of coughing, but existing during rest. The cough is very spasmodic. The patient has lost flesh, and feels weaker. On auscultating moist râles are heard over and around the place where the pain is localised; there is no dulness. Ten days after he was worse. He coughs much, and brings up a green, cheesy, purulent material in large quantity, often by simply leaning down. The pain still "localised." He has a hectic look, perspires much, and has no appetite. Moist râles heard over the upper part of the left lung, front and back, and there is slight dulness. It appeared to me that the man was suffering from bronchectasis, the diagnosis pointing to a dilated bronchus; he was treated accordingly by medicated inhalations and cod-liver oil. The case then became rapidly worse, and I began to fear that there must be tubercular mischief, when one morning during my visit he showed me a hard substance which he had expectorated shortly before my call. On cleaning it, it turned out to be a broken piece of bone, the size of half a French bean, and serrated at its edges as if it had been acted upon by a bone-destroying agent. His wife, who was present at the time of the expulsion, corroborated the fact. She stated that after a very severe fit of coughing the bone had been brought up imbedded in muco-pus, and had been kept for my inspection. From that day the patient improved; the cough gradually abated, and the pain left him. Three months afterwards he was about and working, and had considerably regained flesh.

CASE 2.—P. J——, aged forty-five, a farmer, and a farmer's son, has always been in good health; brothers and sisters all alive and healthy; mother suffers occasionally from attacks of petit mal. He consulted me eighteen months ago for a cough, which worried him much. He had no pain, no physical signs tending to show any organic lesion. Three months later he had symptoms of incipient phthisis, and a month ago his symptoms were these: has lost flesh, and feels weak; has a hectic look; perspires easily, and much at night; pulse 90, small, hard, and rapid; physically the left infra-clavicular area is flattened; there is puerile breathing over the apex of left lung in front, extending to axilla and backwards; no appreciable dulness; vocal resonance increased; voice husky; hacking cough; appetite good; tongue red; spits a white sputum. The days being very hot, he prefers going about to remaining at home; no temperature taken. He takes Grimault's syrup of hypophosphite of lime, as cod-liver oil does not agree even when given in ether; and at bedtime he takes a pill of quinine, opium, and belladonna, which gives him rest and checks the perspiration. Later on I had to stop this latter ingredient, as his tongue got very dry and throat very sore. He now complains of a dull pain localised to the upper surface of the cartilage of first left rib; over that spot moist râles are heard, and dulness detected; continues to bring up white mucus, but no blood. Shortly afterwards he caught cold, and his symptoms became aggravated by gastric derangement. He then took to his bed, feeling much exhausted, caused by diarrhœa. No vomiting, tongue very red and raw, small aphthous ulcers on edge, fungiform papillæ very prominent. Temperature varies from 99° to 101°. Feet œdematous and cold. In addition to the syrup, he takes a mixture of trisnitrate of bismuth and gum, and a mouth-wash of chlorate of potash. Two days later a severe attack of hæmoptysis occurred, and before my arrival the patient had lost a large quantity of blood. He was speechless, skin covered by a clammy sweat, extremities cold; pulse thready, irregular, and very rapid. Ergot in large doses was given; but later on ether spray was pumped over the surface corresponding to a cavity, and with the result of stopping the hæmorrhage. On auscultation crepitation was heard over the left lung, and on listening over the spot where the pain had been felt so long, all the symptoms of a large cavity were detected. Moreover, it was in that cavity that hæmorrhage had supervened; for every time the patient coughs up much blood, which comes out in large quantity, bright in colour, cavernous and amphoric breathing is detected, and on percussion a bruit de pôt-cassé is plainly heard. Then gradually these sounds disappear, to give rise, as the cavity fills again, to crepitation, getting coarser into bubbling sounds, until the blood is again expelled, almost welled out, and amphoric breathing is again heard. The man thought himself dying. I certainly thought that he was in articulo mortis. Six hours afterwards he had rallied a little and could write down his wishes. The pulse were still very weak, almost imperceptible, and must have been about 180 or 190, as it beat so fast and was so faint that I could not count it to a certainty. His sputa were composed of a yellow, cheesy, purulent substance streaked with blood. His treatment was a liberal supply of brandy, beef-tea, and a draught of aromatic sulphuric acid and morphia every three hours, the cough being very spasmodic. During this visit his sister gave me a piece of bone which had been expectorated by him a short time previous, his wife and sister being present. This bone was slightly larger than the one described in Case 1, and had the appearance of those fragments of bone one sees in a carelessly prepared hash; the edges were smooth, and it was evident that it belonged to the bone of a leg of mutton. It is now six weeks since the last event took place. P. J—— has rallied wonderfully; he coughs very much, and suffers from all the symptoms of a large pneumonic cavity.

Remarks.—There cannot exist any doubt as to the cause of all the mischief in both cases. In the first case the *origo mali* is evident from the fact of the patient having recovered almost immediately after the expulsion of the irritating cause. The second case is also clear, although the patient cannot recover. Neither patient ever remembered having swallowed anything the *wrong way*.

It is not unlikely that a good many of the so-called consumptions are due to a more direct cause than tubercles, especially in this country, where the climate is mild, where there is no pauperism, and where sunlight and air are not limited.

In the case of P. J—— an explanation not altogether hypothetical or visionary can be given. The bone having lodged in a bronchus, it created constant irritation, and finally ulcerated through the bronchus into the lung, then through a bloodvessel, causing the violent hæmoptysis. Had the hæmorrhage happened before, the recovery of P. J—— would have been likely. The impacted bone was washed by the blood constantly pouring around it, and forcing the bone from the material in which it was imbedded, and allowing of its expulsion during a fit of coughing.

I have mentioned the use of the ether spray in the treatment of this case. I am not aware that it has ever been mentioned before; it occurred to me when attending a patient with a dormant cavity, which was superficial enough to allow me to mark its progress, and in which hæmorrhage had taken place. I think that if the locality where the hæmorrhage takes place can be detected, and if the same be not too deep, the use of ether spray may be very useful, as it was in both these cases.

May, 1880.—P. J—— is dead, having lived four months after his first attack of hæmorrhage. No post-mortem was allowed.

LONDON HOSPITAL.

ACUTE YELLOW ATROPHY OF THE LIVER; NECROPSY; REMARKS.

(Under the care of Dr. RALFE.)

G. A——, aged eighteen, printer's assistant, was admitted from the receiving rooms of the hospital into Holland ward, July 31st, 1880, suffering from jaundice, but with no urgent symptoms. His mother stated that he was employed by a printer and stationer in the neighbourhood, and had enjoyed fairly good health. He had, however, undergone an operation at Moorfields some time back, and had been under treatment in the skin department of the London Hospital from time to time. The father was said to be rather "scorbutic," and several of the family had suffered from skin disease. There had been no other case of illness in the house from which the patient came. He had not been worried or anxious, nor had he received any other mental shock. There was no distinct history of syphilis, inherited or acquired, though the fact of the father suffering from skin disease raised a suspicion. The mother, however, was healthy. The patient had not been in contact with phosphorus in his trade pursuits, nor had he been exposed to malaria. The present illness commenced three weeks before admission, and came on the day after he had attended a "bean-feast" given by his employers. This was on a Saturday. On the Sunday he felt sick, but on Monday he went to work as usual. On Tuesday, however, he was compelled to lay up, and noticed he was yellow. From that time he had always felt nausea, and the jaundice had steadily increased. He had never felt the least pain anywhere.

On the day after admission, the patient, a well-nourished lad, was found to be deeply jaundiced, the skin hot and dry, emitting a peculiar clayey odour; no eruption was visible. Temperature 98° F.; pulse slow and full. The patient, though conscious, was drowsy and not very intelligent. The abdomen was moderately distended; the liver dulness was slightly diminished in right mammary line, and its lower margin was retracted within the ribs. He had no pain over the hepatic region, nor was any elicited by pressure; the other organs were normal.

On the 2nd the morning temperature was 99·5° F.; evening

97° F. He had been sick several times; he answered questions less readily, and was more drowsy.

On the 3rd the morning temperature was 97° F. He was sick all day, and the bowels were obstinately constipated. Only a very small amount of urine was passed, and this in bed. A sufficient quantity, however, was obtained by Dr. Wolfenden, the house-physician, for examination. He found the percentage of urea to be 1·9 gramme, the reaction extremely acid, specific gravity 1021, and a trace of albumen. Diffused through the urine were small whitish masses, and on standing a sediment fell, in which Dr. Wolfenden determined the presence of leucin and tyrosin. With glucose and sulphuric acid (applied after Francis's method) a faint, but still sufficiently distinct, purple ring was obtained. The area of hepatic dulness showed a diminution since the last note. At about 10 P.M. the patient suddenly commenced shouting and throwing himself about, and was quite unconscious of what was going on around him. This noisy delirium passed off in about half an hour, and the patient became quiet and somnolent. The liver appeared more tender, slight pressure causing the patient to cry out.

On the 4th the morning temperature was 97° F. Patient was very drowsy; could not be roused. The skin was hot and perspiring. Pulse full, bounding, and rapid. He had paroxysms of dyspnœa. At eight o'clock in the evening the temperature was 100·5° F. The patient was in a profound coma; the breathing was rapid and difficult, and the abdomen drawn in at each effort. The patient died shortly afterwards.

Necropsy, August 5th, fifteen hours after death.—Body well nourished, deeply jaundiced. An old scar like that caused by lupus on the face beside nose; no scars on genitals or groins; abdomen distended with gas. On section, the lower margin of the liver did not come into view, being covered by the ribs. The liver removed from the body weighed 2 lb. 2 oz. The gall-bladder was empty, and the common duct, though containing some thin yellowish mucus, did not appear obstructed. The left lobe was much shrunk, flabby, and wrinkled, and the surface was of an olive-green colour. The substance was friable and rotten, and without any appearance of lobules, the sections presenting a uniform greenish-yellow colour. The right lobe was considerably reduced in volume, but not to such an apparent degree as the left. The surface was of a dull red colour, intermixed with patches of greenish-yellow. On section masses of yellow were seen mixed irregularly with deeply reddened tissue, the latter being the most abundant of the two, and was also much firmer and denser than the yellow patches. Under the microscope prepared sections, taken from both tissues, showed that the liver-cells had entirely disappeared, and that the connective tissue was considerably increased. The blood was thin and dark-coloured, and ecchymoses were observed in the subserous structures. The spleen was enlarged, and there was some congestion of the bases of both lungs. The epithelium of the kidneys was undergoing fatty degeneration.

Remarks by Dr. RALFE.—The early supervention of jaundice of considerable intensity in this case, and the time that elapsed before the onset of grave symptoms, and also the fact that the illness was apparently excited by an indiscretion in diet, might at first seem to support the views of those who hold that the disease has a catarrhal origin, and that the icterus is hepatogenic rather than hæmatogenic, and that the fatty degeneration does not occur till the reabsorbed biliary acids have accumulated, owing to some special but not as yet explained condition, to a considerable extent in the blood. But the fact that the gall-bladder was found empty and shrunken, and that no apparent obstruction existed in the gall-ducts, is an objection to the acceptance of this view in the present case; though it might be suggested as possible that the secretion of bile during the last stage of the illness may have been completely arrested, and the bile previously accumulated reabsorbed. If, however, we accept the generally received opinion that the red atrophy is a more advanced condition than the yellow, and is only found in cases which run a slow course, then the great excess of the red over the yellow tissue in the present case leads to the conclusion that the atrophic changes had been in progress some time. Moreover, although the quantity of urea excreted in the twenty-four hours could not be determined, there can be little doubt that it was considerably reduced, since the amount of urine passed by the patient was extremely scanty, and the percentage of urea it contained not above the average. This reduction of the quantity of urea excreted also favours the view that the atrophic changes had been gradual and had commenced before the onset of the grave symptoms. As is well known, considerable discrepancy of opinion exists with regard to the excretion of urea in this disease; some observations recording an increase, others but slight diminution, whilst others note a decided decrease. Dr. Ralfe thinks these observations need not be considered contradictory, but that they express different stages in the progress of the disease. Thus in an early stage or where the disease runs a rapidly fatal course, urea will generally be found increased, an increase probably derived from the rapid metamorphosis of the nitrogenous constituents of the liver tissue itself; as the disease is prolonged the quantity of urea will gradually diminish. Thus in a patient of Dr. Murchison's (Case 103, "Lectures on Diseases of the Liver"), on the fourteenth day after grave symptoms had supervened, "a fair amount of urea" was noted in the urine, whilst on the twenty-third day it is recorded that the urine then contained "very little urea." In a boy aged seventeen years, under Dr. Ralfe's observation at the Seamen's Hospital, the urea was but slightly diminished; in this case the lad had been ill only a short time before he was admitted, and died three days afterwards. Finally, attention may be drawn to the change in the character of the pulse on the supervention of the nervous symptoms, and the sudden onset and brief duration of delirium which preceded the final coma as clinically characteristic.

WESTERN GENERAL DISPENSARY.

CASE OF ACUTE RHEUMATISM; ULCERATIVE ENDOCARDITIS; DEATH.

(Under the care of Dr. PRICKETT.)

FOR the following notes we are indebted to Mr. H. A. Powell, M.R.C.S.E., resident medical officer, who attended the case.

Elizabeth R——, tailoress, single, aged nineteen, was confined last Christmas with her first child, and recovered without any unfavourable symptoms. She was said to have had heart disease for some years, but, otherwise, she apparently enjoyed good health. Her sister and brother had both had rheumatic fever, and were suffering from mitral disease. Patient was not known to have had rheumatic fever; but she had scarlatina in childhood. She was quite well till March 3rd, 1881, when she caught a violent chill, and complained of severe headache and persistent vomiting, which compelled her to leave off work. She was first visited on the evening of March 7th; she had a dry skin, was rambling and could only be roused with difficulty; temperature 104° F.; pulse 130, regular and soft. With the exception of the headache, she complained of no particular pain; respiration 30; occasional cough; a few bronchitic râles could be heard. There was a loud systolic murmur, audible at the apex, which beat in the normal position. The tongue was dry; vomiting had ceased. A suspicious rose-coloured spot was seen on the abdomen; there was some gurgling in the right iliac fossa. The urine was almost normal in quantity, and contained one-sixth albumen. The following day patient appeared much the same, and at times complained of pain in the back. The bowels had acted naturally during the night; there was no abdominal pain or tenderness. On the 9th her mental condition was much worse; she rambled incoherently and was unable to answer any question. The right elbow and wrist were swollen, red, and painful. The urine contained one-fourth albumen. Nourishment still taken well. Ten grains of salicylate of soda were given every four hours. Next day the joints were better and the temperature went down to 99·6°. A little sleep was obtained during the night; in other respects she remained the same. On the following morning she was found much worse. There were sordes on the lips, the tongue was dry, brown, and leathery, and the muttering delirium was more marked. The joints were free from pain and redness. Râles more numerous and more distinct were heard over the chest; resonance normal both back and front. No tenderness or enlargement of liver or spleen. Dr. Prickett saw the patient in the afternoon, and came to the conclusion that she was suffering from septic poisoning, and suggested ulcerative endocarditis as the cause. She was then treated with ammonia and serpentary, and brandy was given in teaspoonful doses every hour. A change was observed in the patient early the following morning, in consequence of which she was visited at 5 A.M. After lying in her sleep on the left side during the night she rolled, on waking, over on to her back, and immediately her left arm and leg were observed to be useless, while her right upper and lower limbs were jerked convulsively. Patient became perfectly unconscious and never spoke afterwards. The left eye was open and the pupil was dilated; the right was closed and the eyeball rolled upwards; the right side of the face was flushed; the left pale and dry; the head was turned to the right. Three petechiæ were noticed—one on the left upper eyelid, another on the left hip, and another near the left knee. Patient was soon moribund. The temperature gradually rose, till at midnight it had reached 105·4°. Shortly after which she died.

Necropsy.—Brain not examined. On the endocardium of the left auricle, and extending to the auricular surface of the mitral valves, was a patch of ulceration, rather larger than a shilling. The right side of the heart was healthy. The lungs were congested at the apices. Nothing abnormal was to be seen in the liver. The spleen was slightly enlarged and studded with infarcts, the largest of which was at the middle of the upper border and surrounded by intense hyperæmia; centrally most of the organ was diffluent. The kidneys were slightly enlarged; the capsules peeled off readily; both organs contained numerous infarcts, decolourised, and not appearing softer than the surrounding tissue.

AYR COUNTY HOSPITAL.

SURGICAL CASES.

(Under the care of Dr. W. J. NAISMITH.)

THE following interesting cases have lately been treated at this hospital.

Nerve-stretching.—J. L——, a miner, aged fifty-four, was admitted August 3rd, 1879, with intense sciatica on the left side. He had formerly been a labourer, when he was exposed to all weathers, and he was much addicted to alcohol drinking. His appearance was strikingly indicative of a broken down constitution. He had been in various hospitals within the last seven years, during which period he had been a martyr to his complaint. He had had all kinds of treatment, including blisters, liniments, subcutaneous injections, courses of iron, arsenic, quinine, &c., together with acupuncture, and the application of the button cautery, but all to no purpose. It was therefore resolved to try stretching the sciatic nerve; and the operation was performed under chloroform on August 10th in the usual manner, and without strict antiseptics, though dressings of carbolic oil, one to twenty, were used. For the first week there was a slight rise of temperature, and pain was complained of in the wound, but these symptoms subsided, and the man made a good recovery, expressing himself grateful for his entire immunity from his old sciatic pain since the day of the operation. This patient was under observation for three months, and during that time there had been no return of his complaint.

Amputation of Forearm in a Child.—T. M——, a child sixteen months old, was admitted in August, 1879, with complete laceration, from an accident with a churning machine, of right hand and forearm, necessitating immediate amputation. This was performed under chloroform, high up—that is, in the upper third of the forearm—by transfixion, and with double semilunar flaps, the vessels being easily secured. Strict antisepticism was not employed, though the stump was dressed with lint, soaked in carbolic oil, one to twenty. The patient was discharged in fifteen days with the cicatrix all but complete.

Amputation of Thigh.—J. G——, aged five years, was admitted, suffering from scrofulous disease of the right knee-joint, which had evidently attained the stage of cartilaginous ulceration. The patient was a poor, sickly little boy in a hectic state, emaciated and racked with pain. The muscles of the limb were characteristically atrophied, and there was globular elastic distension of the knee-joint, with prominence of the superficial veins. The disease was of eighteen months' standing, and the child's general health was evidently fast giving way under the pain, and wakeful nights induced by startings of the limb which he experienced. Amputation was performed, under chloroform, at the lower third of the thigh, by the method of Spence's modification of Teale's operation, and the antiseptic system of Lister was carefully employed. The pulse and temperature, which rose after the operation, subsided to normal on the third day. The stump was dressed on the fifth day under carbolic spray, and the wound continued to heal rapidly without suppuration. The discharge under the dressing remained serous throughout till complete union had taken place in about three weeks. The boy left the hospital gaining flesh rapidly.

Strangulated Inguinal Hernia.—R. G——, aged sixty, a lamplighter, in descending a ladder while in the pursuit of his calling felt something "suddenly give way" in the region of his left groin. He afterwards noticed a swelling there, but paid no further attention to it, in spite of the onset of graver symptoms, such as pain, rigors, and vomiting. He did not apply for admission till the tenth day after descent of the hernia. On admission, there was a left inguinal hernia of the size of a walnut, tense and painful, pain extending to the abdomen, which was swollen and tympanitic. Pulse 120, compressible; temperature 101°. The countenance was pale and anxious. He stated that he had had rigors, vomiting, and complete stoppage of the bowels for three or four days before admission. Attempts at reduction under chloroform having failed, the operation for inguinal hernia was at once performed. The stricture was found at the external abdominal ring, division of the internal pillar of this opening at once relieving the constriction. As the previous long-continued pain and vomiting rendered the condition of the bowel doubtful, the sac was opened, and the knuckle of gut thus exposed was found to be darkly purple in colour, and emitting a somewhat gangrenous odour. Under these circumstances it was not returned, but left near the margin of the wound, the lips of which were approximated by a few points of suture and dressed with a pad of lint. An opiate was given in the evening, when all vomiting had ceased. On the third day the pulse and temperature were normal, the abdominal tympanitis had disappeared, and the patient was free from all pain. He made a good recovery, having been a month in hospital.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Molluscum Contagiosum. — Hepatic Abscess. — External Hydrocephalus. — Sarcoma of Kidney. — Aneurisms of Cerebral Arteries.—Colloid Cancer involving the Spleen.—Spontaneous Disintegration of Calculi. — Intussusception.—Abdominal Tumour.

THE ordinary meeting of this Society was held on Tuesday, May 3rd, the President, S. Wilks, Esq., M.D., in the chair. The meeting was prolonged beyond the usual hour, as there was a large number of specimens brought for exhibition.

Dr. BASIL G. MORRISON read a joint paper by Dr. ALEXANDER MORRISON and himself, entitled Observations on the Nature and Affinities of Molluscum Contagiosum. After stating various views on the subject of molluscum contagiosum, he drew a comparison between the appearances in (1) normal skin from the perineum, (2) hair-follicles and sebaceous glands in the external meatus of the ear, (3) molluscum contagiosum, and (4) an ordinary wart from the scalp. The hair-follicles in the normal skin, and those of the external meatus, he said, are formed of a diverticulum from the rete mucosum, and in the case of molluscum the outer layer is formed of the same. In the normal skin he observed, besides the usual hair-follicles, interpapillary crypts, some of which might be the usual depressions deeper than is the rule, and some of which were atrophic hair-sheaths. In the hair-follicles and glands of the meatus, he said, there was an overgrowth of the peripheral cells and periplast, ending in degeneration at the interior of the follicle to form sebaceous matter. In molluscum contagiosum the change corresponded precisely with that seen in the specimens from the ear meatus. The vacuolation so called was not peculiar to molluscum, but was characteristic of all rapidly growing epithelial cells, and did not indicate an actual emptying out of cell contents, but a transformation of them into a transparent material which could be stained by picric acid. The molluscous bodies were cells which had undergone this change, which is essentially the same as the formation of sebum. The wart was noteworthy only as showing a general process of vacuolation like that in molluscum. The part primarily affected in molluscum was the hair-follicle with the sebaceous gland, or one of the crypts described in normal skin. The formation of sebum-like matter was due to degeneration of cells proliferated into a nearly closed cavity instead of on the cuticular surface. There was uniform hypertrophy of the skin at the free surface in Dr. Morrison's specimens of molluscum, but no trace of the changes described by Lukomsky. The cause of the disease Dr. Morrison said was to be found in the action of any irritant at the part first affected. He could find no proof of a specific agent. Irritation was enough to cause hypertrophy of epithelium, the essential change in molluscum.—Dr. RADCLIFFE CROCKER thought that Dr. Morrison's specimens were taken from fully developed tumours, while it is only when the very earliest growths are examined that their nature can be demonstrated. Such specimens prove the change to start in the rete mucosum, independently of any involutions, in which molluscous bodies appear. A few molluscous bodies can also be seen in otherwise healthy hair-follicles. There are analogies between the tumours and sebaceous glands, but by no means identity, and the peculiar substance has been demonstrated to be neither sebum nor amyloid.—Dr. MORRISON did not consider the formation of molluscum bodies peculiar to this disease, but characteristic of hypertrophying epithelium.

Sir JOSEPH FAYRER showed two specimens of Abscess of the Liver, representing two distinct forms, both contracted in India. One illustrated the multiple pyæmic abscess often following dysentery, the other followed diarrhœa, but was a large single abscess, such as occurs independently of intestinal mischief. The first was taken from a Hindoo, aged twenty-four, who had diarrhœa for a month with fever. He was weak, and had great pain in the belly over the ascending colon, where there was dulness on percussion. He passed several sloughs in his stools. The temperature rose in the evening to 102°, but fell just before death. Post-mortem examination showed small intestines distended with flatus, liver adherent to diaphragm, about normal size, both surfaces covered with nodules, which were abscesses varying in size from a hen's egg to a hazel nut, each circumscribed by a zone of injected tissue. Colon œdematous, thickened in places, atrophied in others. He believed these abscesses started as small local necroses around which suppuration occurred. The second case was that of an officer aged forty-five, of temperate habits; he had dysentery twice, on both occasions accompanied by severe pain over the liver. He also had frequent attacks of malaria. On arrival home he was emaciated, temperature 103°. Bulging and fluctuation over the back of the liver. A large abscess was evidently pointing, and near the surface. It was opened freely, and a pint of pus evacuated. One edge of the ninth rib was necrosed. When liver abscesses point behind there is a great liability to necrosis of ribs. The temperature fell to 99°, and he improved for a few days, but six days later he was seized with severe bleeding, and he died. Post mortem the right lung was condensed. A firm clot was found adherent to the pulmonary artery. Mr. Doran examined the parts. The history pointed to a dysenteric liver abscess, probably multiple, but it proved to be single, and contracted well after its evacuation. He had never seen better examples of the two kinds of liver abscesses, and the latter shows how successful free opening and drainage of large abscesses may be; aspiration is not nearly so useful, as after it the matter reaccumulates.

Dr. DICKINSON showed a specimen of Abscess of the Liver. An artisan aged thirty-four had enjoyed perfect health till one day he went to a boat-race, where he felt cold. Afterwards he ate fifteen mussels with his dinner. Half an hour later he felt ill and had pain in the belly. During the night he was purged, and the diarrhœa lasted for six weeks, till his death. He passed blood and mucus. He was admitted under Dr. Dickinson into St. George's Hospital. His motions were not dysenteric, but uniformly fluid, dotted with blood. His temperature varied from 98° to 103°. There was some fulness on the right side, but no evident enlargement of the liver. At the autopsy the large intestine was in the state of most characteristic dysenteric ulceration in its whole length. There was also a large single abscess at the back of the right lobe of the liver, holding about four ounces of pus. There was also serous pleurisy on the right side. There could be no doubt that his disease arose from the bowel disturbance, and there was no other conceivable cause for the abscess. The case gave strong support to Dr. Budd's view that hepatic abscess is due to some poisonous matter conveyed by the portal vein. The poison of dysentery may be different from that of pyæmia, and this conveyed to the liver may be well capable of exciting abscess. The statistics of Dr. Waring of Madras show that 72 per cent. of fatal cases of abscess of the liver are connected with dysentery; and further, while dysentery may disappear the abscesses cannot, and therefore these figures may not express the whole truth. In 1862 Dr. Dickinson published a case of abscess of the liver in the Path. Soc. Transactions, in which there was an enormous abscess and signs of old dysentery.—Dr. WILKS thought Dr. Dickinson quite right as far as home experience went, but asked if all tropical surgeons did not say that hepatic abscess may occur without dysentery.—Sir JOSEPH FAYRER replied that the large number of cases of liver abscesses have nothing to do with diarrhœa or dysentery. When they have they are most often multiple, and are due to embolisms, but may in a few cases be single. —Dr. LONGHURST agreed with Sir J. Fayrer in thinking single abscesses generally independent of dysentery, but the two affections might be associated. Among natives dysentery is much less commonly associated with abscess than in Europeans, which may be explained by different diet. In the dysentery in the Crimea, hepatic abscess was quite an exception, and it is rare also to find it in English dysentery. But multiple abscess is no doubt due to dysentery.—Dr. N. MOORE thought that primary abscess of the liver being unknown in this country, when found with dysentery we must say that it is dependent upon it. He related a case in which an hepatic abscess was due apparently to an old sinus in the leg. The multiple abscesses have all the appearance of local necroses. —Mr. ALBAN DORAN stated that one of his sections of one of the multiple abscesses was more like an old splenic infarct than anything else—it was dead, not inflamed, tissue.—Dr. F. TAYLOR related a case of Simple Ulceration of the Intestine from a dermoid cyst of the ovary, associated with an abscess of the liver. There were also an old empyema, and a large psoas abscess and diseased bone.—Sir J. FAYRER had seen many cases of abscess of the liver associated with surgical injuries, diseases, and operations.—Dr. DAY had seen cases of pyæmia with small scattered abscesses in the liver and lung.—Dr. WILKS stated that Indian practitioners held that a hepatitis ending in abscess might be primary.—Sir J. FAYRER said that the most recent statistics did not support Dr. Waring's.—Dr. DICKINSON replied that, of course, dysentery might occur without abscess, but doubted if abscess occurred without dysentery.—Dr. S. WEST quoted a case of a man who after a bean-feast had abdominal pain and a very large hepatic abscess; he never had any symptoms of diarrhœa or dysentery.—Dr. O'CONNOR referred to the case of a man of very intemperate habits. After a severe rigor swelling of the liver was found, and on puncturing it sixteen ounces of pus were withdrawn. There was no diarrhœa or dysentery throughout.

Dr. EDMUNDS showed a specimen of External Hydrocephalus. A child, aged two, an idiot, had never spoken or walked, and was blind. Mr. Nettleship found pallor of the optic discs only. Suddenly a fit came on, and next day he died. On opening the skull eight ounces of fluid flowed out; the brain did not fill the cavity. The optic thalami were both shrunken. There was a family history of mental affection.—Dr. HALE WHITE referred to a family of five in which four were hydrocephalic, and to seven other cases of hydrocephalus of whom two had hydrocephalic relations, and two others had relations with large heads. Of these eight cases the bones of the head were fully ossified in two, and the sutures almost closed in two others.—The PRESIDENT remarked that while formerly hydrocephalus with large head was stated to be sometimes external and sometimes internal, it had now been shown that in all such cases the fluid was contained in the ventricles of the brain; and Dr. Edmunds's case was no exception to the rule, for the head was not a large one, but of the usual size, and it was an interesting question to decide whether the secretion of the fluid was primary or secondary to the small brain.

Dr. ABERCROMBIE showed drawings and sections of a Growth in the Hilus of the Kidney, with secondary growths in each kidney. The tumour was a small round-celled growth, and was similar to three cases shown by him last session.

Dr. W. M. ORD showed three specimens, the first of Spontaneous Disintegration of Vesical Calculi. This was the sixth specimen of the kind which Dr. Ord had exhibited before the Society. He was allowed to do so by the kindness of Mr. Thomas Smith, of St. Bartholomew's Hospital, who had sent him the calculi for examination. The fragments, weighing over three ounces, represented a large number of pisiform calculi, and had been removed from a man aged sixty-nine by Mr. Thomas Smith. Their removal was effected at two sittings, by means of Bigelow's apparatus, some of the pieces having been crushed on the second occasion. The fracture, however, of most of them had evidently occurred before, the broken surfaces and edges being smoothed by friction and covered by new deposit. The calculi were mainly composed of uric acid. They appear to have fallen to pieces from without inward, not to have been disrupted from within. Their disintegration appeared to be due partly to their feeble cohesion and their friability, partly to the presence of a minute fungus closely allied to, if not identical with, penicillum glaucum. The second case was of Aneurisms of Cerebral Arteries. The specimen showed three aneurisms, one of the anterior communicating artery of the circle of Willis, one on a branch of the right middle cerebral, one on a branch of the right anterior cerebral. The first two were of the size of large peas, the third very small indeed. The basilar and other large arteries were marked with transverse rings of calcareous degeneration; there were no minute aneurisms in the fine arteries. The subject was a woman aged fifty, who was suddenly seized with apoplexy, and died in a few hours after two attacks of convulsions. The cause of death was rupture of the aneurism of the anterior communicating artery, with extravasation over the surface of the hemispheres beneath the arachnoid. There was no affection of the valves of the heart, but moderately advanced granular contracted kidney. The third was a specimen of Colloid Cancer of the Spleen. The specimen was obtained from the body of a man aged thirty-five, who had enormous colloid cancer of the parietal peritoneum and omentum. The growth invested the liver and stomach, but did not invade their tissue. The coats of the intestines were not affected, but the spleen was invested and invaded by the colloid, so that little of its proper tissue was left. The colloid had also projected in a hernial fashion at the umbilicus, and through other parts of the abdominal wall, displacing the muscles without involving them. Colloid invading the spleen is so rare that Dr. Ord thought it right to exhibit the specimen. Two cases had been described in the Transactions of the Society, one by Sir William Jenner and Dr. Quain, the other by Dr. O'Connor. A third had been reported by Dr. Schweninger in 1876.

Dr. TURNER showed a specimen of Intussusception. A month after admission to the North Eastern Hospital a child, while still confined to bed, was seized with symptoms of intussusception. A typical tumour was felt in the position of the transverse colon. Injection of water into the colon made it recede to the right groin. After six days scybalous motions were passed; but peritonitis came on, and death ensued on the tenth day. The intussusception consisted of a part of the ileum passed through the ileo-cæcal valve. There was no extravasation of fæces. On manipulation the intestine at once ruptured. There was extensive ulceration of the cæcum below the valve, probably due to the irritant effects of the intussuscepted bowel; but the ulcers may have been anterior to the intussusception, and such a view afforded a possible explanation of the occurrence of the intussusception under otherwise unlikely circumstances.

Dr. DAY showed a Tumour removed after death from a girl aged four. Mr. K. Thornton made an exploratory incision and found the tumour to be solid. The tumour extended from the second right rib and filled nearly the whole of the belly; the liver was displaced to the left, the lungs hidden, and the apex beat of the heart was under the left second rib. The tumour grew in two months.—Mr. A. DORAN stated that the tumour was a spindle and round-celled sarcoma.

Mr. SHATTOCK showed a card specimen of atresia of aortic orifice with adhesion of the valves.

The meeting then adjourned.

EPIDEMIOLOGICAL SOCIETY.

AT the meeting of this Society on the 6th ult., Sir Joseph Fayrer, K.C.S.I., President, in the chair,

Dr. JOSEPH EWART read a paper on Scrofula, Tuberculosis, and Phthisis in India. Prior to the year 1840 we do not find much mention made of these deviations from health. Green, in 1845, proved the existence of phthisis among natives of Hourah and Midnapore, and Edward Goodeve, in the same year, made similar observations among patients attending the civil hospital and dispensary at Cawnpore. Since then the prevalence of scrofula and tuberculosis in various phases had been recognised by Allan Webb, T. W. Wilson, Morehead, and the author. Admitting these facts, there is, nevertheless, evidence from experience and the statistics of Dr. Bryden to show that phthisis is not nearly so frequent among natives as among European soldiers and their families. This observation is upheld in drawing a comparison between the gaol population and the British soldiers, somewhat modified, it is true, in Lower Bengal and Assam by excessive overcrowding. The comparative infrequency of pulmonary tuberculosis forms no exception to the predominating rule, even when full allowance has been made for latent and undiscovered tubercle. It is quite rare to hear of whole families, or of several members of a native family, being carried off by phthisis. White swellings of joints and strumous enlargements of the glands, or cicatrices resulting from suppurating scrofulous glands, are comparatively infrequent. According to Bryden, the admissions per 1000 of strength with phthisis during the six years ending 1876, amounted to 9·0 among the soldiers of the European army of India, to 8·8 among those of Bengal, to 10·8 among those of Madras, and to 8·0 among those of Bombay; to 9·6 among women of the European army of India, to 10·4 among those of Bengal, to 8·0 among those of Madras, and to 8·7 among those of Bombay; to 8·3 among the children of the European army of India, to 8·2 among those of Bengal, to 8·7 among those of Madras, and 8·2 among those of Bombay. In the British army generally, during 1861–62, the ratio of admissions with phthisis per mille was from 9 to 10 of mean strength; and in the American army, during 1861 to 1863, from 8 to 9 per 1000. In the native army of the Bengal Presidency the corresponding ratio during 1871 to 1876 amounted to 2·5; Bengal proper and Assam to 3·9; the Gangetic Provinces to 2·9; Rohilcund and Meerut to 3·0; Agra and Central India to 2·6; the Punjab frontier force to 2·1; and of the Central India irregular force to 0·8. For the same period, the ratio of admissions with phthisis per mille of native prisoners in Bengal amounted to 4·2; in Lower Bengal and Assam (where overcrowding and humidity are excessive) to 8·9; in the Gangetic Provinces and Oude to 3·2; in the Central Provinces, excluding Saugor and Jubbulpore, to 1·5; in Agra and Central India to 2·1; in Rohilcund and Meerut to 2·8, and in the Punjab to 2·1. The comparative infrequency of tubercular disease among natives is attributed (1) to the open-air life led by the people and the respiration of air uncontaminated, to an unusually great extent, with the products of that which has already been breathed; (2) to the wholesomeness of the food consumed, which is composed of a large proportion of the vegetable, with a minimum of the animal, aliment, and is well seasoned, well cooked, and presented in an easily digestible form; (3) to the general temperance of the people, and the habit of the protracted suckling of the young often beyond the completion of the first dentition, or even longer; (4) to the influence of high temperature in mitigating the severity of bronchial, pulmonary, and pleuritic disease; (5) to the greatly diminished prevalence of measles, whooping-cough, scarlatina, mumps, &c.; (6) to the comparative exemption of native children and youths from inherited scrofula. The vexed question as to whether longevity is promoted by transferring persons predisposed to scrofula, or actually suffering from tuberculosis or confirmed phthisis, from this and other temperate latitudes to India, was next dealt with. There is an impression that persons born of tubercular parents, but in whom there is no evidence of tubercular growth, do better in India than at home. They certainly escape to a marked extent the frequent attacks of bronchial catarrh, pneumonia, and pleurisy, which are rightly associated with the origin of tubercular growth in the bronchial glands and the pulmonary parenchyma. In so far as this is so, such persons are benefited. The greater exemption of children and youths from measles, scarlatina, whooping-cough, and mumps is also a clear advantage. Again, the warmth of the climate is soothing to the pulmonary mucous membrane, whilst the freer action of the skin, so long as it is not profuse, and the greater expansion of the chest due to rarefaction of the air, may be regarded as favourable. But these advantages are to a great extent counteracted by repeated attacks of malarious and season fevers, which not only light up tuberculosis in the predisposed, but in the course of time produce anæmia and cachexia, also conducive to its development in such individuals. The dampness of the climate in many parts, together with the great and exhausting heat, contribute to this dyscrasia. Add to these an unusual proclivity to serious bowel complaints, and then not much will remain to be said in favour of advising those descended from consumptive parents to exchange a career at home for one in India. The causes already mentioned, rightly understood, go far to explain why, in such cases, the tendency is rather to the progressive augmentation of tubercle in the lungs than to its arrest or diminution, with or without—as the disease advances—tubercular ulceration of the solitary glands of the large and small intestine, and of the agminated glands of the ileum.—In the discussion which followed, Dr. Murray, Dr. Gordon, Dr. Russell, Dr. Lilburn, Dr. Douglas Powell, Dr. Buchanan, and the President took part.

Dr. BUCHANAN read for Dr. Squire an account by Dr. Léon Colin of the Destruction by Small-pox of a Troupe of Esquimaux who recently visited Germany and France.

OBSTETRICAL SOCIETY OF LONDON.

AT the meeting of this Society, held on the 6th ult., Dr. Matthews Duncan, President in the chair,

Mr. DORAN showed Microscopic Sections from a Dermoid Cyst, removed by Mr. Thornton from a woman, aged thirty-one. The wall consisted mainly of patches of true skin, with sebaceous glands and hair-follicles. There were tooth-like bodies, which consisted of cartilage. Small secondary cysts projected from the inner wall. In certain long, narrow cavities in the subcutaneous tissue was seen well-formed mucous membrane, having a perfect cylindrical epithelium, with numerous involutions.

Mr. KNOWSLEY THORNTON showed a Dermoid Cyst of the left ovary, which had been entirely twisted off from its pedicle, and had become attached to the right side of the omentum. The patient first came under his care seven years ago with a doubtful abdominal tumour. She had since had four children, and during the last pregnancy the tumour gave her great pain. On April 2nd, Mr. Thornton removed the tumour together with a cystic tube, the remains of the twisted pedicle on the left side, and a cystic right ovary.

Mr. DORAN showed also a Female Fœtus which displayed extreme arrest of development of the genito-urinary tract. It was born at the seventh month, and breathed for a quarter of an hour. There was ectopia of abdominal viscera, club-foot, and spina bifida. The bladder consisted of two lobes, and between them, superiorly, the intestine opened from above. The ureters were impervious. On the right side was a Fallopian tube, and tubular, thick-walled half-uterus; ovary atrophied. On the left an ovary and Fallopian tube, the uterus being an impervious cord.

The PRESIDENT exhibited several small Oxalic Acid Calculi, which had been removed from the wall of the female urethra, in which they had become imbedded.

Dr. GODSON showed the Uterus, &c., of a woman aged twenty-five who had died in the Dorking Infirmary. Mr. Hopcroft, who sent up the specimen, could give no history except that the woman was believed to be unmarried, and was in a dying state when admitted. Two pints of blood were found within the peritoneum, old adhesions attached omentum, &c., to the uterus, both Fallopian tubes were dilated and tortuous. The outer end of the right tube enclosed a fœtus of about six weeks' development in a fleshy mass containing villi. He thought the adhesions might have been due to gonorrhœa.

The debate on Dr. Barnes's paper "On Missed Labour" was then resumed.

Dr. JACKSON related the case of a lady who, when three months and a half advanced in pregnancy, underwent great fatigue in travelling in India. After this there was no increase of size, but menstruation did not recur. About the time that labour should have taken place she took a long ride on a restive horse, expulsive pains were induced, and an oval mass containing a very small fœtus came away. —Dr. EDIS said that several instances had been recorded by different authors, as Simpson, Meigs, and Atlee, in which gestation had been prolonged for one, two, or three months beyond the normal time. But in many such cases there was strong presumptive evidence that they were really instances of extra-uterine gestation, the supposed cervix being really a fistulous opening. Dr. Müller, after investigating forty-five cases of alleged missed labour, concluded that "there does not exist an authentic observation of retention of the fœtus within the womb beyond the term of ordinary pregnancy." In this conclusion he fully agreed, unless Dr. Barnes's case were an exception; but even this might have been partly interstitial, and not an ordinary intra-uterine pregnancy.—Dr. GALABIN had met with one case of supposed missed labour, which tended to confirm the view that many cases so described were really instances of extra-uterine fœtation. There was an effort at labour at full term, and he saw the patient two months later. There was then a sanguineous, somewhat offensive, discharge from the vagina, and the patient's condition had become grave. A catheter was passed through the cervix into a cavity resembling the uterus, and gave exit to a fluid like that which had escaped from the vagina. After dilatation of the cervix by a tent the breech of the fœtus could be felt, presenting through a round opening, which seemed to be the internal os. This turned out to be an aperture in the uterine wall at the point at which it was sharply retroflexed, and the gestation proved to be abdominal, the sac lying in front of the fundus. If no autopsy had been made all who saw the case would have continued to suppose the fœtus intra-uterine.—The PRESIDENT said that for his own part he believed in the occurrence of protracted gestation and missed labour. The probability of their occurrence was much supported by the facts that they occurred in the lower animals, and that missed abortion or missed miscarriage occurred certainly in women. He did not think the occurrence of labour premonitions a necessary part of missed labour. He thought the term lithopædion, at present often used as synonymous with mummified fœtus, should be better defined. The fœtus never became calcified like a uterine fibroid, but calcification affected only the membranes, and sometimes the adjacent parts of the fœtus.—Dr. GODSON called attention to a case which came under his observation at St. Bartholomew's, which formed the basis of a paper by Dr. Greenhalgh on "Missed Labour" in the eighth volume of the Hospital Reports. The case was one of "missed abortion," and not of "missed labour," and the head of the fœtus should have been described as of four months and a half, not of six months' development.—Dr. BARNES, in reply, said in reference to Mr. Spencer Wells's suggestion that the pregnancy might have been intra-mural, that there was no evidence in favour of it, and intra-mural gestation generally ended by a fatal cataclysm at the second or third month. The rhythmical action of the uterus could not be expected to be detected when the uterine contractility was impaired after the death of the fœtus. He would make a point of studying Dr. Duncan's cases. Meantime he thought that protracted gestation for an indefinite time required better proof than we possessed. He thought the term "missed abortion" a singularly unhappy one, and that the term "concealed" or "incomplete abortion" was much to be preferred. He could not agree with Dr. Duncan that the terms lithopædion and mummified fœtus were commonly used as synonymous. A "stone child" should at least be stony, and the distinction was the more important since Cruveilhier had insisted, rightly as he believed, that a lithopædion was never found in the uterus.

Dr. HEYWOOD SMITH related a Case of Delivery through an Imperforate Vagina. The patient was thirty-one years old, married ten years; pregnant for the first time. The vagina was only one and a half inches long, and was completely closed by a roof of the normal thickness of vaginal tissue. It was congenital, and there was no cicatricial tissue. Her mother, a trained nurse, was aware of the malformation. The author was called to see the patient at the British Lying-in Hospital, when she had been in labour thirty hours. On admission the urethra was so patent as to admit nearly two fingers, and, from the husband's account, coitus probably took place per urethram. The vaginal roof was lax, as the head was arrested at the brim. The os was completely dilated, and the bones of the head had begun to overlap. A careful examination failed to discover the slightest depression, or any indication as to any aperture, however small. The patient was therefore placed under chloroform, the vaginal roof was picked up with forceps, and a cut made at once with scissors directly through it, when, the finger being passed through the aperture thus made, the head was felt; the opening was then enlarged by tearing with the fingers until a passage was formed large enough for delivery, which was speedily effected by means of the long forceps, and a living female child extracted. The patient made a good recovery, and examination last December showed a normal vagina with but a slight constriction, not at all hard, formed by the remains of the previous vaginal roof.

Dr. Percy Boulton narrated a case of Imperforate Vagina. The patient was aged eighteen, married. Catamenia were always very painful, and were followed by "green waters" for several days. The vagina was found to be a cul-de-sac about one and a half inches deep, and no opening whatever could be felt. An examination was made under chloroform, and a dilating speculum introduced. On either side of the vaginal terminus a small opening was then found, through which a probe could be passed. The openings were dilated with tangle, and there were then found—(1) a normal uterus, (2) a tripartite vagina, the upper portion being duplex, separated by a septum, which formed a triangle, with its base downward. A small communication between the two was found close up to the vaginal neck. The central block was divided by passing whipcord round by a sound having an eye at the end, and attaching it to an écraseur. A vulcanite vaginal plug was worn for three weeks, and the patient then went home well.

MEDICAL OFFICERS OF HEALTH SOCIETY.

At a meeting of this Society held at 1, Adam-street, Adelphi, on the 22nd ult., Dr. John Syer Bristowe in the chair, Dr. C. Kelly read a paper on "The Distribution of Diphtheria in West Sussex." The object of the paper was to give an account of the conditions under which diphtheria appeared during the past six years in West Sussex, and to show the influence of soil and weather on its distribution. After describing the geology of the district, Dr. Kelly pointed out by a series of statistical tables that diphtheria is far more frequent upon a stiff clay soil than it is upon more porous formations, the disease rate showing the difference much more forcibly than the death-rate. Omitting the gault, where the facts are too few to be of value, the weald clay stands first as being the formation on which the disorder is chiefly prevalent, while the porous Folkestone and Sandgate beds of the lower greensand are nearly free from the disease. On the pervious chalk very few cases are met with, while on the upper greensand, which lies to the north of the chalk hills, cases frequently occur. It is not difficult to show that there is a general relation between the rainfall and the prevalence of diphtheria. The years in which the greatest rainfall took place were accompanied by a greater number of cases. A comparison between the rainfall and the number of cases of diphtheria of different years can only be roughly approximative, because when once the disease has become epidemic its continuance may extend beyond a period of wet weather. The year 1879 was the wettest year known since 1860, and there was a marked increase in the number of cases of this disease. Most of the outbreaks of diphtheria in West Sussex have occurred round commons or village greens, a cold damp air appearing to favour the spread of the disease. Tables were shown in which it appeared that half the cases of diphtheria were between three and nine years of age; very few infants are attacked even when other members of the family are suffering from the disorder. The death return is not a good criterion of the prevalence of the disease in different years. In one year a large number of cases was attended by a very low mortality, while in another epidemic, although but a few persons were attacked, they nearly all died. The number of new cases in each month varied very much. In 1875 the greatest number occurred in May; in 1876, in September, October, and November; in 1877, in July, August, September, and November; in 1878, in March, April, and November; in 1879 the number was high in every month except August and September; and in 1880 the greatest number occurred in July and September, while there were none in the last three months of the year. The occupation of the people is chiefly agricultural. There is no material difference in the mode of living in the different parts of the district. Some of the cottages are good, but the disorder has not fallen with greater severity on the very poor than on those who are more comfortably housed; for in many old cottages which are hardly fit to live in, the disease has attacked the inmates less severely than those who live in comfortable and substantial cottages. One point may be noticed in the condition of the people who live in the district where diphtheria is most prevalent, and that is the close relationship of many of the families; intermarriage is very common, and an infusion of fresh blood is not often noticed. In such districts the children are fairly fed, but they do not seem able to resist any acute attacks of disease; they are not intelligent, and seldom make much progress with their education. Diphtheria is distinctly a disease of rural districts, and differs from other catching disorders in being most prevalent in those cases where the people are thinly spread, and where isolation exists naturally. It is worthy of notice that children who are attacked are generally those who have to go long distances to school, and the condition of the road is such that they are invariably exposed to wet and cold. Finally, Dr. Kelly has found no relation to exist between animals and vegetables on the one hand, and diphtheria on the other. In the discussion which followed, the President, Dr. Bond, Dr. Corner, Dr. Tripe, and Mr. Shirley Murphy took part.

WEST HERTS MEDICAL ASSOCIATION.

The sixty-sixth half-yearly meeting of this Society was held at Watford on the 20th ult., Dr. P. Hood, the President, in the chair. Dr. A. Clarke read an interesting paper on the Treatment of Diphtheria, being the continuation of a paper that he had read to the Society on a former occasion. In the discussion which followed most of the members took part. Dr. Steel exhibited a Calculus that he had extracted from a youth aged eighteen. It had also been exhibited to the Pathological Society; and it was considered peculiar, as it consisted of cystine, but having a well-marked ring of oxalate of lime in the middle of the stone. Dr. Paxon exhibited part of the Index-finger, which had been torn off by machinery, and had drawn out with it twelve inches of tendon. The man made a good recovery. Dr. F. H. Berry exhibited the Supra-renal Capsules from a patient who had lately died of Addison's disease. The boy was eighteen years of age, deeply bronzed. He had been in the infirmary several times, with no definite symptoms except weakness, and during the last illness obstinate vomiting. He died suddenly. The supra-renal capsules were both affected, filled with tubercular masses, and gritty to the feel. Dr. Brett brought a boy on whom he had performed tracheotomy for diphtheria. He was six years old. Drs. Hobson and Paxon promised to read cases at the next meeting in October.

Dr. Iles was elected treasurer, and Dr. A. T. Brett continued honorary secretary.

Bequests and Donations to Medical Charities.

Mr. Samuel Courtauld, late of Gosfield Hall, bequeathed £2000 each to the London Hospital and the Essex and Colchester Hospital, £1000 each to the Charing-cross, the Royal Free, the City-road Consumption, and the East London Children's Hospitals. Miss Elizabeth Elmslie of Edinburgh bequeathed £10 each to the Royal Infirmary and the General Dispensary, Aberdeen. The Halifax Infirmary becomes entitled to £500, by the will of Mr. Farrar and to £50 by the will of Miss Sarah Farrar, sister of the above. Mr. J. St. G. Burke, Q.C., late of the Auberies, bequeathed £100 to the St. Leonards Hospital, Sudbury. The Consumption Hospital, Liverpool, has received £550 under the will of the late Mr. Philip John Ashton.

Reviews and Notices of Books.

The Quarterly Journal of Microscopical Science. Edited by Messrs. LANKESTER, BALFOUR, DYER, and KLEIN. No. LXXXII. April, 1881.

THIS number contains the following interesting memoirs: 1. The Minute Anatomy of the Branchiate Echinoderms, by P. H. Carpenter, M.A. 2. On Young Stages of Limnocodium and Geryonia, by Professor Lankester. 3. The Origin and Significance of the Metamorphosis of Actinotrocha, by Ed. B. Wilson. 4. The Minute Anatomy of the Organ of Jacobson in the Guinea-pig, by E. Klein. 5. Histological Notes, by E. Klein. 6. On the Development of certain Microscopic Organisms occurring in the Intestinal Canal, by D. Cunningham. 7. The Development of Starch Grains, by A. Schimper. 8. On the Cause of the Striation of Voluntary Muscular Tissue, by J. B. Haycraft. 9. On the Relation of Micro-organisms to Disease, by Joseph Lister. 10. Observations on the Appendages and on the Nervous System of Apus cancriformis, by Professor Ray Lankester.

Dr. Cunningham's paper is one of the most interesting of the above-named articles, and the conclusions at which he has arrived are: that peculiar parasitic forms may be specially associated with particular forms of disease without holding any causal relation to them; that the monadic, amœbal, and sporoid bodies so abundant in many choleraic excreta are all developmental forms of one species of parasite, which he proposes to call Protomyxomyces coprinarius. This parasite appears to be closely related to the organisms included within the Protist groups of Protomonadinæ and Myxomycetes, and in certain respects seems to represent a connecting link between them. It is not confined to choleraic or even to human excreta as a basis, and only attains its full development external to the bodies of the animals within which it occurs. Its immature forms occur parasitically as normal inmates of the digestive canal in certain of the lower animals. In the human subject, both in health and disease, they are very frequently present in varying numbers. During health their number and activity are limited, due to repressive influences exerted by the normal intestinal contents as a medium. Their excessive abundance in certain forms of disease is due to abnormal conditions of the intestinal contents permitting of the occurrence of processes of rapid multiplication. Normal human excreta do not form a medium in which any further development of the parasitic elements outside the host body can occur. On the contrary, the normal series of fermentative changes through which the excreta pass after exit from the body ensures the complete destruction of the parasitic elements. No such destructive effect, however, is exerted by the changes occurring during the decomposition of the excreta in certain lower animals, especially cows and horses, and here the parasitic elements in them escape from the body, undergo further processes of development resulting in the production of reproductive bodies, securing the continuance and diffusion of the species. Such excretal matters therefore serve as a constant source wherein parasitic elements may be transferred to the bodies of other animals. Human excreta, which have passed through the initial processes of decomposition, and which have thus become alkaline, allow of the continued existence and multiplication of elements of the parasite, which may then obtain access to them, and may thus serve as a second centre of propagation. The introduction of the reproductive elements of the parasite into the human body is mainly effected through the medium of the air. The introduction of the reproductive elements *per se* seems to be quite innocuous. The special association of the parasite with intestinal disorders appears to be dependent on the abnormal condition of the intestinal contents allowing of the rapid multiplication of reproductive elements which may obtain access to them. Mr. Haycraft's paper on the Cause of Striation of Voluntary Muscle is also an interesting one, and deserves study.

The Journal of Anatomy and Physiology. By Professors HUMPHRY, TURNER, MCKENDRICK, and CREIGHTON. Vol. XV. Part 3. London: Macmillan. 1881.

THE contents of this number are—1. The Bones, Articulations and Muscles of the Rudimentary Hind-limb of the Greenland Right Whale, by Dr. John Struthers. 2. The Stridulatory Apparatus of Callomystax gagata, by Mr. Alfred C. Haddon. 3. The Sternum as an index of sex and age, by Mr. Thomas Dwight. In this paper the author makes some important statements from a medico-legal point of view in correction of ordinary accepted dates. 4. Dr. J. M. Hobson on the Mechanism of Costal Respiration. 5. The Membrana propria of the Mammary Gland, by Dr. Mansel Moullin. 6. On Double and Treble Staining of Microscopic Specimens, by W. M. Stirling, M.D. 7. On the Comparative Anatomy of the Lymphatics of the Mammalian Urinary Bladder, by George Hoggan and Mrs. Hoggan. 8. A Dissection of a Case of Epispadias, by Dr. R. J. Anderson. 9. On the Morphology of the Muscles of the Tongue and Pharynx, by Dr. R. J. Anderson. 10. A Contribution to the Pathological Anatomy of Pneumonokoniosis, by Mr. Thomas Harris. 11. On the Histology of some of the rarer forms of Malignant Bone Tumours, by Mr. Robert Maguire. 12. On the Morbid Histology of the Liver in Acute Yellow Atrophy, by Julius Dreschfeld, M.D. 13. The Relationship between the Muscle and its Contraction, by Dr. Cash; and, lastly, some Anatomical Notelets, by Dr. J. Macdonald Brown.

Revue de Médecine. No. 4. April, 1881. *Revue de Chirurgie.* No. 4. April, 1881. Paris: Germer Baillière.

THESE journals are rich in matters of interest, and fully justify the separation of the *Revue Mensuelle* into its two components. The present number of the Medical Review opens with a paper upon Hepatic Sclerosis by M. Talamon. He deals with that form which is secondary to cardiac disease, and maintains that the induration of the liver is in great measure due to concomitant inflammatory changes in the arteries of the organ. He concurs with Wickham Legg and others in the observation that there is no production of connective tissue around the central vein of each lobule, the cirrhosis being in the portal areas, as in the alcoholic form, and points out that in some cases there supervenes a severe form of jaundice, owing to the destruction of the hepatic cells. The next paper is on Ephemeral Subcutaneous Nodules and Rheumatism, by MM. Troisier and Brocq. As we propose to deal with this elsewhere, it will suffice to say now that the authors draw attention to a comparatively novel matter, which we understand will form the subject of a communication to the forthcoming Congress by two English physicians. M. Barié contributes the second part of an extensive study on Rupture of the Cardiac Valves, and summarises many cases which are scattered through medical literature. A case of essential anæmia (fatal) with hæmorrhagic diathesis is related by M. Foucheraud from M. Lépine's clinique. The "Revue Critique" of this number is devoted to an analysis of the subject of Tendon-Reflex, by M. Ollive. The number concludes with brief abstracts of the proceedings of many medical societies, French and foreign.

In the Surgical Review one of the editors, M. Nicaise, describes a form of intestinal stricture following hernial strangulation, which was relieved by operation five years before the development of further symptoms. Enterotomy was performed, but the patient succumbed, and the cause of the obstruction was found to be the existence of bands of adhesion between the contiguous portions of a loop of intestine, the result of a local peritonitis at the earlier date. M. Féré writes upon strangulated hernia in the infant, and the apoplexy of the testicle to which it may give rise. He enumerates at the close of his paper fifty-six cases of strangulated herniæ in children under two years of age. M. Delens contributes the concluding portion of a paper upon Sub-hyoidean Ranula. There is also an exhaustive review of Nephrectomy, by M. Lannois, based upon thirty-nine cases, most of which we believe have been summarised by Mr. Barker in his papers on the subject read at the Medico-Chirurgical Society. A tolerably full report of the proceedings of the Société de Chirurgie is also a feature of this number.

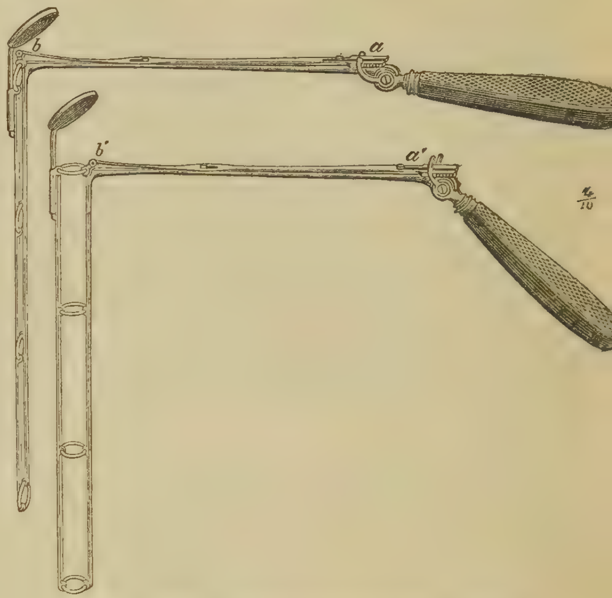
Brain. April, 1881.

THE current number is one of more than average interest. The opening article is by Dr. Bucknill, and is a lengthy but valuable discussion of the judicial opinions of the late Lord Chief Justice Cockburn on Lunacy. The differential diagnosis of the various forms of paralysis is sketched in a somewhat tabular article by Dr. Byrom Bramwell. Austin Flint, junior, considers in the next paper the Cause of the Movements of Ordinary Respiration, assigning to reflex action a smaller share in the process than some authorities are inclined to admit. Dr. Julius Althaus discusses some points in the Diagnosis and Treatment of Brain Disease, the chief therapeutical points being the wonderful effect of the constant current in some cases of organic disease. The explanation of some curious Illusions of Motion is the subject of a very interesting article by Dr. C. S. W. Cobbold, and Dr. Bevan Lewis continues his very important description of the methods of preparing, demonstrating, and examining cerebral tissue. Of the reviews, the most important is a very thorough analysis of Rosso on the Circulation of the Blood in the Human Brain by Dr. Rabagliati. A series of Clinical Cases by Drs. Warner, Atkins, Ashby, and Buzzard conclude the number.

New Inventions.

A NEW ŒSOPHAGOSCOPE.

THIS instrument consists of two parts—a stem and a skeleton tube. The stem is made up of a handle and a shank, between which there is a hinge. The skeleton tube is only formed when the instrument has been introduced into the gullet; before that it consists of two flattened wires placed anteriorly and posteriorly, connected above and below and at certain intervals between these points by rings. When the rings lie in the vertical position the wires are separated from each other only by the thickness of the rings; but when the latter are thrown into the horizontal position the two wires become separated, and with the rings constitute a kind of skeleton speculum. At the top of the back wire there is a slot, into which the stem of a laryngeal mirror is fitted. By the upper figure it will be seen that the handle and shank are almost in a line—a position which greatly facilitates the introduction of the instrument. When the "body" has been passed down the œsophagus, the operator, holding the handle in his hand, but leaving the index-finger free, presses with the latter on the upper part of the shank near the handle. The result of this is to turn the rings from the vertical to the horizontal position, and thus to open the speculum and expand the gullet. With a view of causing as little irritation as possible before withdrawing the instrument, the operator should close the speculum by pressing the under part of the shank (near the handle) with his thumb. Tubes from three to five inches in length can be bolted so securely to the end of the shank that they are as safe as if the whole instrument were made in one piece.

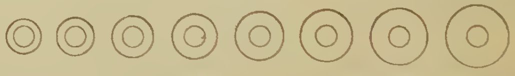


The upper drawing shows the instrument ready for introduction into the throat; the lower one, the same instrument *after* introduction.

This instrument has been manufactured by Messrs. Mayer and Meltzer, of Great Portland-street, under the direction of Dr. Morell Mackenzie, who has been using it for nearly a year.

UTERINE DILATOR.

AN instrument for dilating the cervix of the uterus has been sent to us by Messrs. Maw, Son, and Thompson, who state that they have constructed it according to suggestions and designs given by Dr. James, of Thurloe-square. The invention consists of a sound made of plated copper, and having the ordinary shape of a uterine sound; but the handle, which is fastened by a screw, can be readily unshipped and replaced. The main feature of the instrument, however, is the employment of the stem as an axis, upon which slides a vulcanite tube equal in diameter to a No. 5 catheter. The tube is seven inches long, and can be forced onwards until it becomes arrested by the bulb that ends the curve of the sound. The tube may be withdrawn without moving the axis, and the next size tube may then be driven as far as the point of arrest. The tubes, of which there are eight, constitute a graduated series, from No. 5 to No. 12.



ABDOMINAL BELTS.

A SET of three abdominal belts is made by Messrs. Worth et Cie. for use under the following circumstances:—One is for support during pregnancy; one, which contains a metallic compression plate, is for use immediately after confinement; and the third for wear after the puerperal period. These belts are well made, and seem well adapted to fulfil the object for which they are intended.

MR. G. L. SENEY has given 200,000 dollars and a site for the erection of a cottage hospital in Brooklyn, U.S.A.

THE LANCET.

LONDON: SATURDAY, MAY 14, 1881.

IF it were not that we have in vaccination and revaccination practically an absolute protection against serious and fatal small-pox, the present aspect of affairs as to that disease in the metropolis might awaken the gravest anxiety. Even as it is, this aspect is not to be regarded without much misgiving. It discloses an amount of unprotectedness against the disease within the metropolitan area which we were largely unprepared for, and which proves that the negligence of revaccination in the metropolis is fully as great as, in fact greater than, that of primary vaccination, as shown by the official returns. And this, indeed, is the chief lesson to be learned from the persistent activity of small-pox in London, a lesson which goes to the root of the matter as regards the prevention of the disease, but which is in danger of being swallowed up in the present active discussion regarding the merely provisional procedure for checking the prevalence of the disease by the isolation of the sick in hospitals. Such isolation should be regarded as a necessary part of the preventive treatment of small-pox, so long as any appreciable portion of a population remains unprotected by efficient vaccination and revaccination; and under the circumstances of the metropolis, from the immense movement of population in it causing peculiar difficulties in tracing unvaccinated children, and the vast immigration of people of whose history in regard to vaccination it is practically impossible to keep account, there must be for long to come, it is to be feared, an unusually large proportion of the unprotected within its area. But in regarding hospital accommodation as an important aid in preventing the extension of the disease among those persons, we must not lose sight of the fact that our hope of stifling the disease, and preventing recurring epidemics, must rest in reality upon the success of our efforts in promoting vaccination and revaccination. And revaccination at the present moment particularly concerns us from this point of view. The true teaching of the present epidemic is to the effect that we want in London, and, in fact, in England generally, the practice of revaccination so extended as that it shall be as fully spread and as efficiently carried out as primary vaccination. As it is, we learn from the official vaccination returns that infants and young children are, thanks to the present generally effective arrangements for primary vaccination, being eliminated from the victims of small-pox; and we require such a development of revaccination among children above the age of puberty and persons of older age as is being carried out and is now being successfully effected as to vaccination among infants and young children. If the persistence of the epidemic of small-pox in the metropolis will turn the attention of the community more intently to this view of the subject, nothing but permanent good will come out of this temporary deadlock about hospital accommodation. The lesson as to revaccination has been dinned into the ears of the people at large and the local vaccination authorities persistently for the last ten years, but the ears have proved mainly deaf ones. Perhaps more heed will be given now when the community must provide for treating small-pox more largely in their households than hitherto, exposing the inmates and neighbours to tenfold danger of the loathsome contagion. How many persons have reflected that of the deaths from small-pox registered within the Bills of Mortality last week, half, with the exception of two, were registered in private houses? That is to say, that half the cases occurred and ran their course under circumstances of infinite danger to the other members of the family, and when no efficient control could be exercised over the diffusion of the contagion to other families. And this condition of things, owing to the failure of hospital accommodation, is being repeated over the length and breadth of London, in its wealthiest as its poorest quarters. Yet we possess an efficient remedy against small-pox in general revaccination, a remedy not only easily obtained, but involving little trouble, and actually provided for all who care to have recourse to it at the public expense! Is it not possible to bring this remedy more fully into play? In this respect, although we must condemn the shortsightedness of the Local Government Board in its arrangements as to the provision of animal lymph so far as these would promote more general revaccination, we must admit that the Board has spared no effort to arouse the local vaccination authorities of the metropolis and the inhabitants at large to a just sense of the importance of revaccination—and this, we are glad to believe, not without some considerable success. Revaccination has probably never been so largely carried out in the metropolis as it is now, under the combined terror of the epidemic and the monitions of the Local Government Board. But are we not in a position to go further? The key to the success of our primary vaccination is compulsion. Is it so far out of reach of existing statecraft that compulsion in some form could not be brought to bear on revaccination? In view of the incalculable benefits which have been obtained in regard to small-pox among bodies of men who are indirectly compelled to submit to revaccination, and of which the letter-carriers of the London postal district form, as Dr. WALLER LEWIS has recently told us, so remarkable an example, surely it ought to be possible to devise some legislative means by which the population at large, above puberty, might obtain the same immunity, and the metropolis and kingdom generally freed from these recurrent alarms of small-pox. At any rate, over and above the question of small-pox hospital accommodation for the metropolis now awaiting solution, let it be remembered that we have immediately at hand a more certain and much simpler protection against small-pox in efficiency of vaccination and revaccination; and it is to this remedy, and not to hospital accommodation and isolation of cases therein, we have to look for the ultimate control of this formidable disease.

◆

IT is now ten years since the researches of FRITSCH and HITZIG, followed a few years later by those of FERRIER, laid the foundations of the modern doctrine of Cerebral Localisation. We term it modern because, though it had been previously mooted on various grounds, and to a certain extent empirically established by BROCA, it is only with the above-mentioned researches that the stage of what professes to be exact scientific method and verification commenced. The question thus raised has excited the active interest of physiologists, psychologists, and pathologists, and a vast amount of literature in the form of special treatises or contributions scattered among the scientific journals of every country has grown up, dealing with the subject in its various aspects. The present seems a convenient time for taking a brief survey of the results achieved, more particularly in reference to clinical medicine and pathology, without in any way attempting to pre-determine the conclusions to which the controversy still proceeding may be carried.

The starting-point of the doctrine and all its subsequent developments was the discovery of the fact that application of the stimulus of the galvanic or induced current to certain regions of the cortex cerebri excited movements on the opposite side of the body—movements which varied according to the position of the electrodes, and which were held to be definite, uniform, and capable of accurate prediction. In this way areas or "centres" were defined and marked off, and their homologues established in the brains of different animals. In the dog these areas were grouped in the neighbourhood of the crucial sulcus; and in the monkey, in the convolutions bounding the fissure of Rolando.

The facts described by HITZIG and FERRIER were confirmed by subsequent individual investigators and by joint committees, and have since been widely accepted. If nothing else has been established beyond these data, altogether apart from their actual significance, an important light has been thrown on the causation and diagnosis of certain affections well known to clinical observers. The occurrence of spasms or convulsive movements, limited to one side of the face or to one limb, or beginning in a limb, and spreading in a definite manner to the whole of one side, had been carefully studied by HUGHLINGS JACKSON, and connected with "discharging lesions," or irritation of motor convolutions functionally related to the corpus striatum. The researches of HITZIG and FERRIER, and the subsequent investigations of CARVILLE and DURET, LUCIANI and TAMBURINI, and others, both as to the effects of localised irritation of the cortex and the experimental induction of epileptiform convulsions in the lower animals, have afforded evidence in favour of the accuracy of HUGHLINGS JACKSON'S hypothesis. The numerous instances lesions of successful diagnosis of the seat of discharging founded on the observations of HUGHLINGS JACKSON, and the facts of experiment on the brain of the monkey in particular, have led to the recognition of "Jacksonian epilepsy," and its regional diagnosis, as a matter of ordinary instruction in clinical medicine. These results have also exercised a considerable influence on the current views as to the pathology of epilepsy in general, and in many cases at least the phenomena are considered more in accordance with primary irritation of the cortex cerebri than secondary to changes in the medulla oblongata. A new departure has also been attempted in the direction of the prehistoric practice of trephining; and elaborate investigations of cranio-cerebral topography have been made by BROCA, TURNER, FÉRÉ, LUCAS-CHAMPIONNIÈRE, POZZI, AMIDON, &c. As to the ultimate practical issue of these inquiries, it would be at present premature to express an opinion. Even the near future is obscured by doubt. The interpretation of the movements resulting from electrical irritation applied to the cortex cerebri has naturally given rise to considerable diversity of opinion. While the discoverers of the phenomena referred them to irritation of the grey matter of the hemispheres, others looked upon them merely as the results of physical conduction to underlying motor tracts; and the fact that similar movements could be produced by electrical irritation after the grey matter was removed, was considered by BURDON-SANDERSON, G. H. LEWES, &c., to place this beyond all question. On this point the researches of ALBERTONI and MICHIELI, and those of FRANCK and PITRES have an important bearing. These investigators found that though electrical irritation of the medullary fibres subjacent to the cortical grey matter at first excited movements similar to those resulting from the application of the electrodes to the grey matter itself, yet all reaction ceased after from four to five days, a period coincident with the degeneration and loss of excitability which occur in motor nerves after separation from their centres; whence it is argued that the medullary fibres between the cortical centres and the lower motor nuclei bear the same relation to the nerve-cells of the cortex as the spinal motor nerves to the multipolar cells of the anterior cornua. The investigations of VULPIAN and others on the lower animals, and those of CHARCOT and his pupils in cases of lesion of the so-called motor area, have shown that descending degeneration occurs in the pyramidal strands of the spinal cord as the direct result of such lesions; and working both from the standpoint of secondary degeneration and from that of the fœtal development of the spinal tracts and their cerebral relations, FLECHSIG, in his elaborate work on the subject, traces a direct connexion between the grey matter of the convolutions bounding the fissure of Rolando (the motor area) and the anterior cornua of the spinal cord.

The histological researches of BETZ and MIERZEJEWSKY, and those of BEVAN LEWIS, also show that in this area there is a characteristic lamination and grouping of the ganglionic cells not found in other regions of the cortex. It has also been experimentally proved that destruction of the cortical centres in the lower animals causes, for the time at least, disorders of mobility in the opposite limbs—effects which the localisers state may be limited to a limb, or certain movements of a limb only, according to the position of the lesion. But as to the exact nature of these disorders, and their duration, the most diverse views have been expressed, and the controversy still continues. HITZIG, NOTHNAGEL, from an experimental point of view, and BASTIAN from a theoretical standpoint, regard the affection as one of muscular sense, or kinæsthesis (BASTIAN); SCHIFF, MUNK, and TRIPIER hold that there is a loss of tactile sensibility, while FERRIER holds that motility only is affected. FERRIER accounts for the amount and duration of the motor paralysis in different animals by the relative degree of organisation of the motor activities in the centres situated below the cortex proper. In four-footed animals the independent organisation in the lower centres is much greater than in the monkey and man, and hence in time the paralysis or paresis at first apparent on destruction of the cortical centres disappears; whereas in the monkey and man, whose movements are more intimately dependent on the cortex, the paralysis is permanent. Others account for the recovery by a hypothesis of functional substitution by other portions of the cortex. GOLTZ opposes localisation in general, and considers the hypothesis of functional substitution invoked by some localisers as inconsistent with their doctrine. He is of opinion that every portion of the cortex is in relation more or less with every function exercised by the cerebral hemispheres, and attributes the temporary disturbances which ensue on cortical lesions in the dog to inhibition, for the time being, of the uninjured parts. He thus in a measure supports the doctrine of FLOURENS, and the pathological views of BROWN-SÉQUARD, as to the *modus operandi* of cerebral lesions. GOLTZ does not obtain limited paralysis either of motion or sensation from cortical lesions, but a combination of motor and sensory paralysis, general and special, the degree depending not so much on the position as on the extent of the lesion established. But as GOLTZ has not restricted his lesions in the manner indicated by the localisers, his experiments have been objected to by them as irrelevant to the question. Nevertheless, GOLTZ has succeeded in showing that dogs retain extraordinary capabilities even after most extensive bilateral destruction of their cerebral hemispheres, if time be given for the subsidence of the primary disturbance caused by the operations. Though profoundly demented they yet exhibit obscure signs of sensation, general and special, and the power of directing their movements in accordance with them; facts which lead him and others to suppose that every portion of the cortex participates in feeling, will, &c., and is independently related to all the voluntary muscles and sensory organs of the body.

Leaving these physiological controversies and turning to the facts of clinical medicine and pathology, we find that within the last ten years numerous observations have been published in reference to the effects of cerebral lesions; cases observed and described with a due regard to the accurate topographical situation of the lesions which the localisers have shown to be of such essential importance, and the want of which has vitiated the great majority of former clinical records. In the works of CHARCOT and PITRES, FERRIER, GRASSET, DE BOYER, LANDOUZY, NOTHNAGEL, LUCIANI and TAMBURINI, MARAGLIANO, and in various journals at home and abroad, there are to be found records of several hundred cases recently observed, destructive lesions of the so-called motor area with motor paralysis of the opposite side, which may be general, or limited to the leg, the arm and leg, the arm, the face, or arm and face, according to the extent and position of the lesion, the results of clinical observation apparently harmonising to a considerable extent with FERRIER'S localisation of the motor centres in the monkey. The intensity of the paralysis varies with the completeness of the destructive lesion, but the cases are numerous of incurable paralysis, followed by descending degeneration of the pyramidal tracts and the development of late rigidity in the paralysed limbs, in connexion with lesions purely cortical.

It is claimed by the localisers that destructive lesions of the motor area invariably cause motor paralysis, but a few cases have been put on record by JACCOUD, MANCINI, CUNNINGHAM, and MAGNAN in favour of the occurrence of partial lesions in the motor area without any evident symptoms during life. There does not, it is said, appear to be any unequivocal case on record of general destructive lesion of the so-called motor area without motor paralysis.

On the other hand, lesions outside the motor area, in the prefrontal, occipital, and temporo-sphenoidal lobes are alleged to occur without motor paralysis or secondary degeneration of the pyramidal tracts. It is with respect to the effects of lesions of this so-called latent area that attention has of late been more particularly engaged. FERRIER drew a distinction between the significance of the movements resulting from electrical irritation of the anterior and posterior regions of the hemispheres, holding that the latter were indices of sensation. Following up these indications by the method of circumscribed lesions, he mapped out special areas for sight, hearing, tactile sensibility, smell, and taste. Owing to the commonly negative results of disease in these regions, and the paucity or indirectness of positive confirmatory facts, this part of FERRIER'S work has been overshadowed by the localisation of motor centres. But the question has of late been assuming greater prominence. Though the accuracy of FERRIER'S sensory localisation has been severely criticised by MUNK, yet the fact of a localisation of areas of special sense has been admitted by him and by LUCIANI and TAMBURINI; and certain modifications as regards the extent and relations of the visual centres recently introduced by him and his colleague Professor GERALD YEO bring the results of physiological experiment into greater harmony with each other. These experiments point to the region of the occipital lobe and angular gyrus as specially related to vision. Cases have been recorded of ocular spectra in connexion with irritative lesions in this region, and not a few cases are also on record which seem to point to the connexion of hemiopia with lesions in the medullary substance of this portion of the hemisphere. As regards hearing, FERRIER'S localisation of an auditory centre has been confirmed by MUNK, and by LUCIANI and TAMBURINI. Differences, however, exist as to the exact position of the centre in question. It is asserted that there are no cases on record of loss of hearing from cortical lesion, but facts have been published in favour of the association of "word deafness" with lesions of the superior temporo-sphenoidal convolution of the left hemisphere. The localisation of special centres of tactile sensibility, smell, and taste, is maintained almost exclusively on physiological data, the clinical facts at present on record failing to establish any direct relationship between cortical lesions and abolition or impairment of these faculties. It seems at first sight not a little remarkable that so much difference of opinion still exists among physiologists not merely on matters of detail, but on the main question of localisation in general. The differences, however, appear to be not so much on matters of fact as on the mode of interpretation; and when it is considered that the cerebral organisation may differ in different animals, and that in them all that concerns subjective relations is a matter of pure inference, the facts may reasonably appear differently to different investigators. On the other hand, in the experiments of disease in man, the testimony of the patient renders the determination of questions as to subjectivity more simple. Hence, viewed mere y in their physiological relations, the facts of disease in man must form an indispensable factor in all considerations relative to cerebral functions and their localisation. Many problems still remain unsolved, and much is yet to be made out of even the most common forms of cerebral disease.

Careful clinical observation will prove of incalculable service towards the satisfactory elucidation of one of the most important questions in medical science.

THE return of Dr. DANFORD THOMAS by a majority of votes, numbering more than five to one of those polled for his opponent Mr. BOLTON, is satisfactory. Making the largest allowance for the circumstance that the successful candidate was doubly qualified, being a medical man and a member of one of the Inns of Court, it is nevertheless evident that the constituency has again declared its allegiance to the principle that medical knowledge is pre-eminently necessary for an efficient discharge of the duties devolving on an official whose express business it is to investigate the causes of death. This principle is so clearly self-evident that there should never be the smallest doubt as to the result of a contest in any district. The claim urged on behalf of lawyers, as such, is manifestly of the weakest. The conditions under which inquiries of the nature entrusted to a Coroner must always be conducted are such as to prevent the functions of his office being adequately performed by any gentleman without medical knowledge, however able and honest he may be. If the legal profession should retort that ignorance of law is a disqualification, we may reply that it is always easy for a medical man to acquire a sufficient acquaintance with the law. His education specially qualifies him for such a course of study; and we have no objection to concede that it is expedient that any man contemplating an attempt to obtain the post of Coroner should thus qualify himself. On the other hand, no mere lawyer, however well educated and perfectly trained in his profession, can possibly obtain a useful—or we will go farther, and say more than a dangerous—knowledge of medicine without passing through the full curriculum necessary for a diploma. It would be idle to ask lawyers to qualify as doctors, but it is neither vain nor unreasonable to demand that doctors becoming candidates for this office shall possess an adequate knowledge of the law and legal methods.

We have said that the Coroner's Court is hampered by the conditions under which its functions are exercised. This must be obvious. There can never be any close approach to a strictly judicial procedure while Coroner and jury are required to carry out a personal investigation. That they are required to do this is evidenced by the rule which enjoins an actual inspection of the body of the deceased, and by the laxity of procedure which enables a juryman to lay aside his character as a judge, and to become a witness at any stage of the investigation. These may seem small matters, but they show the nature of the so-called Court. It is, in fact, nothing more than a somewhat ungainly and inconvenient agency for exploring the mystery of an uncertified death. All attempts to magnify the office beyond its legitimate proportions must tend to discredit it. The Coroner is neither an officer of the public peace, properly so called, nor is he a supplementary registrar under the superintendence of the Registrar-General. It is not legitimately his business to allocate the crime of murder or manslaughter, nor is he required to make the verdict of his jury a scientific contribution to the statistical roll kept at Somerset House. If he *can*, without causing needless expense to the ratepayers, or straining his powers, point to the perpetrator of a capital or grave offence against the person, and so help to hand the offender over to justice, he is justified in so doing. Again, if he can so precisely specify the cause of death as to make his return available for—what are believed to be, useful—statistical purposes, he may perform the collateral service; but these offices, which are too often spoken and thought of as parts of the Coroner's "duty," are essentially outside it and contingent. The sole business of this official is to ascertain whether death has occurred "by the visitation of God" (to revive an old but *legally* sufficient formula), or whether it has been caused by some non-natural act or agency. For the necessary search in an obscure case medical knowledge is undoubtedly indispensable. The Court is not constituted, and can never be made competent, to deal with the evidence of experts as a superior Court is *supposed* to deal with such testimony. The inability of non-medical judges, of any and every rank, to weigh medical evidence is apparent, and it constitutes a grotesque blot on our judicial system; but the impotency of a non-medical Coroner is a serio-comic absurdity, in which even the loafers of the district pot-houses find occasion for merriment. Whatever reforms await the office and Court of the Coroner—and both are much in need of the axe or the pruning-knife,—it must be evident that to find the "cause of death" it is indispensable to employ an official who has a professional acquaintance with the scientific subjects lying within the scope of his inquiry, and who will know how to direct the search in proper quarters. The essential and all-important difference between the Coroner's Court and any other Court known to our system, is that while all other tribunals are charged to deal only with the evidence brought before them, and not to inquire beyond the limits of the purview, the Coroner and his Court are charged to investigate the unexplored mysteries of a case, and not only by his officer, but in person and with the aid of his jury, to ferret out the truth with regard to the death of the person whose remains he, so to say, takes into his custody. There is nothing like this elsewhere in our judicial system. The Coroner, or Crowner, is the direct representative of the Crown for purposes which have in recent times been restricted to those relating to the death of the QUEEN'S subjects: as such he must be a person qualified by special knowledge to search among the mysteries of death; or, in other words, he must be a medical man.

It may seem ungrateful, after the persistent adherence of the voters of Middlesex to the principle of selection inaugurated when the late Mr. WAKLEY was returned as the first Medical Coroner for the County, to express the hope that this may be the last occasion on which the appointment will be left to the freeholders; but the constituency, as at present existing, must admit that it is an anomaly to give a vote to the smallest *freeholder*—for example, even the owner of a grave—while the vote is denied to the largest *leaseholder*. In the old days, when the "Crowner" was chiefly, or at least equally with his other functions, the local claimant of treasure trove and property lost or disentailed, for the

Crown, it was natural that the electors should be freeholders of the district. They were empowered to select the person in order that they might guard their own rights by presenting an impartial man to the office, and he was himself required to be a freeholder, to the extent of a knight's fee, in order to afford a sufficient guarantee for his integrity and to make him representative of that class whose rights the Crown might possibly invade. Now, however, that the Coroner is no longer actively employed in this assertion of the rights of the Crown, but has almost exclusively to search out the causes of death, there is no sufficient reason why he should not be appointed to this office by the Chief Coroner, the Lord Chief Justice of England, or the Secretary of State for Home Affairs. In any case there is no reason why the electors should not be leaseholders and occupiers, as well as freeholders. As it is, the election of Coroner is one of the most antiquated of formalities, and entails costs and an amount of trouble on a candidate which are out of all proportion to the emoluments of the office he seeks. In the case of a purely vexatious contest the burden is intolerable. Before another vacancy occurs we trust the whole matter may receive the consideration of Parliament, and that a long-delayed, but really necessary, measure of reform may be introduced and—which is much more—carried into effect.

◆

THE terms of the Royal Commission on the Medical Acts, published in THE LANCET of last week, are so well chosen and show such a good grip of the points to be investigated, that we feel it to be unnecessary to go into such detail in exposition of these matters as otherwise we should have felt. The Commission, by way of preamble, says, "It is of importance to all classes of our subjects that the conditions under which persons are permitted to represent themselves as qualified medical practitioners should be such as to afford the best attainable security for their skill and knowledge in medicine and surgery." It proceeds to refer to divers representations in Parliament, and otherwise, of the unsatisfactory state of such matters; says that Her Majesty is of opinion that further inquiries should be made into the grant of medical degrees, memberships, fellowships, licences, and other diplomas, by universities, colleges, and bodies in the United Kingdom; into the courses of education and examination, payments, and other conditions required as a preliminary to such grant, and into the skill and knowledge which such degrees, fellowships, and licences or diplomas represent; into the conditions of registration, of removal from the Register, the position of registered persons abroad, and of practitioners here who have been educated and examined abroad; into the constitution, functions, powers, and procedure of the Medical Council; its relation to the various bodies and to the medical profession; and generally into the results of the Medical Act of 1858, and the various Acts amending it. This is a large and comprehensive Commission, and if it be executed with care can scarcely fail to issue in a report that will supply a basis for legislation which will place our medical institutions on a more satisfactory footing than at present.

The Royal Commissioners will not proceed far without finding out some curious facts. If they are of an antiquarian turn of mind, they will find much in the history of the medical bodies to engage their interest, especially the remote origin of many of the bodies, and the singular functions and crafts with which some of them were identified. Instead of wondering that a number of "trusty and well-beloved" subjects of Her Majesty have been selected in an advanced stage of the nineteenth century to adjust these institutions to the present time, they will wonder that such an adjustment had not been made before, and that the work of the medical reformers in 1858 was so incomplete. Most of the nineteen bodies can boast of centuries of existence, and their charters take us back to the time when surgery was represented by barbers. Before the incorporation of the Royal College of Surgeons of Ireland in 1784 there existed a guild of Barber Surgeons in Dublin whose charter dated as early as 1446. The Royal College of Surgeons of Edinburgh, on July 1st, 1505, had a "Seill of cause granted by the Town Counsell of Edinburgh to the crafte of Surgerie and Barbours." For many years this was the only body in Scotland licensed to distil spirits. The present charter of the Royal College of Surgeons of England sets out with reciting the letters patent granted by King EDWARD IV. at the supplication of the freemen of the Mystery of Barbers of the City of London using the mystery or faculty of surgery.

The histories show not only the age of many of the bodies which have to be dealt with, but the curious limitations of their functions. Such bodies as the above dealt only with the surgical side of disease, and this in a very primitive way. Though the notions of the time gave much importance to surgical methods of relief—bleeding, cupping, tooth-drawing, &c.,—there were other functions to be discharged which called for bodies which would license persons capable of rendering other services: making and compounding medicines, or the still higher work of prescribing medicines to be dispensed by the barber surgeons or the apothecaries. So arose the Companies of Apothecaries, essentially trading companies in character, and the medical degree granting function of the universities, which in England the Commissioners will find still in a very imperfect state, though very great advance has been made of late years at Cambridge, and even at Oxford.

Successive charters and successive Acts of Parliament, notably the Act of 1858, have greatly elevated the functions and enlarged the jurisdiction of the nineteen bodies, which, the Commissioners will find, license men to practise, granting qualifications of the most variable value as tests of knowledge, either general or professional. There is, however, this remarkable survival of the dark ages in all, or in all but one, of the qualifications granted—viz., they are all one-sided: a qualification in medicine only, or in surgery only, or in midwifery only; not—except one perhaps, the licence of the Royal College of Physicians of London—in all the three branches of the one great art of medicine. This is an absurdity which cannot survive the present inquiry. It is simply monstrous that a complete qualification cannot be obtained from one examining body, be it in England, Ireland, or Scotland. Nothing but the trade instinct, which is found even in professional corporations, could have preserved such a one-sided arrangement, with its two sets of fees.

The Act of 1858 removed one curious limitation which it is important at this crisis to recall—the limitation of the jurisdiction of the respective bodies. Prior to that Act diploma of the English Colleges licensed its holders to practise only in England. The licensing virtue of the Scotch qualifications was more restricted still. Before 1858 the Royal College of Physicians of Edinburgh had legally no jurisdiction beyond the walls of the old town of Edinburgh. The jurisdiction of the Royal College of Surgeons of Edinburgh extended to eight specified counties—the three Lothians, Berwickshire, Peeblesshire, Selkirk, Roxburgh, and Fife. That of the Faculty of Physicians and Surgeons extended over four counties—Lanarkshire, Renfrewshire, Ayr, and Dumbarton. Even graduates of the ancient Universities of Scotland had no legal right to practise, save only by the courtesy of the Scotch Corporations. Such was the almost parochial restriction of the chief Scotch Corporations before the Act of 1858, which gave to their qualifications henceforth an Imperial value. Unfortunately the legislation of 1858, while properly abolishing all territorial limitations and distinctions of qualification, provided no means for adequately securing an approximation to equality in the examinations to be passed, only vesting the duty of superintendence in a Medical Council, without powers, and made up predominantly of the nineteen bodies to which the Act gave Imperial jurisdiction, without taking any account of their parochial proclivities. Hence the necessity for fresh and sound legislation. In another article we shall try to show the working of the General Medical Council since its creation in 1858.

Annotations.

"Ne quid nimis."

MEDICAL ASPECTS OF TEMPERANCE.

A MEDICAL conference has been held at Bristol under the auspices of the Bristol United Temperance Mission. A very careful paper, conceived in a scientific spirit, was read by E. M. Skerritt, M.D. Lond. Dr. Skerritt concluded with the following propositions:—1. That the exact physiological value of alcohol as a food, and its destiny in the human economy, are matters of doubt. 2. That experience teaches that total abstinence favours the enjoyment of the highest vigour of mind and body. 3. That it cannot be demonstrated that alcohol in moderation is necessarily injurious. 4. That the sum total of any virtue that alcohol may possess as an article of diet is utterly insufficient when compared with the sum total of evil that it produces in the community. Most medical men will subscribe largely to these propositions. Dr. Thompson, of the Bristol Lunatic Asylum, regretted the presence of the public, which he thought hindered free discussion of the question in its medical and scientific bearings. We think that some sides of this question are not yet fit for discussion in a mixed assembly. He objected, too, to the common and certainly rather vague statements about alcohol as a cause of insanity—an objection illustrated by the remarks of the speakers at the conference. Dr. Thompson thought not more than 3 per cent. of cases due to drink; the superintendent of the Colney Hatch Asylum said drink was the cause, "directly or indirectly," of 40 per cent. of cases, and that the Commissioners in Lunacy placed the cases at 14 per cent. There is nothing scientific in such data, and, therefore, nothing true. Dr. Richardson, in an evening address, controverted the opinion that the disuse of alcohol leads to the use of other narcotics. He had taken notes of thirty-three opium-eaters, all of whom used alcohol. He also refuted the notion that teetotal children were pale and unhealthy, and that teetotalers consumed more food than others. There is certainly a most extensive agreement in the medical world against the use of alcohol in any but the most moderate quantities, and to the effect that it should be taken only in connexion with food and in diluted forms. Those who take raw spirits or strong wines, at odd times and apart from food, must be ignorant indeed of the nature of the human body and of the laws of health. The power of resisting its bad effects varies, for unknown reasons, in different constitutions. The case of a man, aged eighty-four, is mentioned by Anstie, who lived for twenty years on a bottle of gin and one small finger-length of toasted bread per day. We have known such instances; but the assumption by any particular person that he had such a constitution as this implies would be a presumption that would probably in the great majority of cases be soon punished by fatal disease.

THE MICRO-ORGANISMS OF TUBERCULOSIS.

ACCORDING to some recent experiments by Deutschmann, the conclusions of Klebs and Schüller, that the active agent in the infection of tuberculosis is a micrococcal organism, cannot be accepted without further investigation. In the experiments the production of tubercles of the iris was taken as the test of the activity of the virus. Tuberculous pus from the human subject, if allowed to stand for two or three days in a perfectly clean vessel closed with cotton-wool, separates into two layers; the upper clear and yellowish in colour, and the lower composed of thick pus. The former is found on microscopical examination to be completely free from pus cells, but it contains a large quantity of very small bodies in vigorous movement, which correspond exactly with the micrococci described by Klebs and Schüller as characteristic of tuberculosis, and which Deutschmann has also found constantly in tuberculous material. He injected this serum, containing the micrococci, into the anterior chamber of the eyes of guinea-pigs. The pus from which the serum was obtained came from three different individuals. The result was that in every case the injection of the serum was without effect, while that of the lower layer invariably caused tuberculosis of the iris, after the lapse of the usual period of incubation. This result, although unexpected, was remarkably constant. Even when considerable quantities of the serum were injected, it never caused tuberculosis. The fluid from the anterior chamber of the eyes, in which tubercle had been thus produced, was injected into the eyes of other rabbits, but without result, although the liquid contained pus corpuscles and the micrococci which are supposed to constitute the *materies morbi*. If, however, the liquid was taken at a late stage, when, in addition to the pus and micrococci, it contained the products of degeneration of the tubercular formations on the iris, tubercles always resulted from the inoculation. Some liquid from the anterior chamber of a child suffering from tubercles of the iris was also injected into the eye of a rabbit, but without result, although it was found to contain numerous mobile micrococci. These results, Deutschmann concludes, can only be explained on three hypotheses: (1) that micrococci have nothing to do with the tubercular infection, or with the tuberculous virus; (2) the micrococci serve only as the vehicles of the tubercular infection when they can germinate in a suitable soil, such as is furnished by the lower layer of the tubercular pus; and (3) the specific organisms were placed in such unfavourable conditions that they had no pathogenetic action. It is conceivable, for instance, that the micro-organisms were so rapidly absorbed from the anterior chamber, and so rapidly rendered harmless in the blood, that they had no effect, whereas the slower absorption of the lower pus layer gave them time to multiply in it.

"THOUGHT-READING."

THE demonstration given by Mr. Irving Bishop, before a large and distinguished assembly of literary and scientific men, including some of the leading members of our profession, was in some respects disappointing. Perhaps the rather striking title of "thought-reading," and the *imprimatur* given to Mr. Bishop's powers by Dr. Carpenter and Professor Huxley, raised expectation higher than was warrantable. At the same time there can be no question that so far as Mr. Bishop is concerned, the demonstration was perfectly genuine, and free from any suspicion of trickery. Amongst those present were the Right Hon. Lyon Playfair, M.P., Mr. Francis Galton, Professor Croom Robertson, Dr. Brydges, Mr. Moncure Conway, Rev. Llewelyn Davies, Professor Burdon Sanderson, Mr. Romanes, Dr. Wilks, Dr. Andrew Clark, Dr. Hack Tuke, Dr. Bastian, Dr. Pye-Smith, Dr. Buzzard, Dr. Whipham, Dr. Coupland, Mr. E. Hart, Professor Lankester, Dr. Donkin, Dr. Curnow, and Mr. Spencer Wells. It is hardly necessary to describe in detail the various tests that were applied to Mr. Bishop; suffice it to say that they were limited to three kinds. In the first, he undertook to find an object placed in a part of the room during his absence, by requesting the gentleman placing it to keep a distinct image of the place in his mind, whilst Mr. Bishop, who was brought into the room blindfolded, kept the back of the left hand of the gentleman who had concealed the article pressed against his own forehead. He travelled round the room in this fashion until he came to the place, when he stopped, and soon lighted on it exactly. This experiment was repeated two or three times, Mr. Moncure Conway, Dr. Lyon Playfair, and Professor Croom Robertson being the subjects of the experiments. The condition for success was that the "thinker" should be all the time forming in his mind an exact and vivid picture of the place where the object was. Mr. Bishop, who is a slightly-built, pale young man, of neurotic temperament, always became apparently much exhausted by the process, no such visible effect being produced upon the one whose "thoughts" were being filched. The first two experiments were perfectly successful. In the one Mr. Moncure Conway, in the other Dr. Lyon Playfair, were those upon whom they were tried. A third and fourth experiment of the same nature, in which Professor Croom Robertson was the subject, failed; and the cause of the failure was interesting. Professor Robertson had placed the article in the hand of a gentleman who had subsequently left the spot where he was seated when he received the article. Mr. Bishop, after the necessary application of Professor Robertson's hand to his forehead, travelled all over the room without coming to a standstill, and apparently at a loss to indicate the place. At last Professor Robertson explained what had happened. In another experiment with Professor Robertson, Mr. Bishop soon correctly lighted on the place where the object had been first concealed, but could not find its final resting-place, although he hovered over the spot. Of the second variety of experiments, one was successful, the other unsuccessful. Professor Ray Lankester had to form a vivid mental picture of a pain, from which he said he was at that moment suffering, and Mr. Bishop, taking his left hand, and pressing it against his forehead, soon hit upon the precise spot at which the Professor had an aching tooth. At a later period of the evening the same experiment was repeated with Dr. Pye-Smith, who had a pain in the hand, but without success. In the third variety of experiments, in which Mr. Bishop pointed out letters in the word thought of by the individual whose hand he held as above, only one was successful. Dr. Lyon Playfair was the subject again; but the experiment failed twice with Dr. Bastian, Professor Robertson, and Mr. Brooke. In all this Mr. Bishop was perfectly frank and open; he reiterated more than once that he could offer no explanation of the failures any more than of the successes; and, for our own part, we are neither surprised at the failures, nor consider that they tell against the genuine character of the performance. What is instructive, however, is this, that those gentlemen with whom Mr. Bishop succeeded were possibly more nervously constituted than those with whom he failed; so that unconsciously they told by the involuntary contraction of their muscles what was passing in their minds. Mr. Bishop claims to have discovered a new fact in science. He has no part with the Spiritualists, whose manifestations he asserts he can repeat when he has seen them. So far as the exhibition on Monday evening went, he failed to satisfy us that there is in him any special faculty for discerning mental operations; for all the experiments, it must be remembered, were done through the contact of the hand of the subject with the forehead of Mr. Bishop, so that any slight tremor or involuntary muscular movement would be at once perceived by him. It is conceivable that in some individuals the imaging in their minds of the precise spot of a pain &c. would cause an involuntary and unconscious contraction of their muscles when this spot was reached; but it is only just to Mr. Bishop to admit that even this interpretation is not wholly satisfactory. Mr. Bishop is not a clever trickster, who wishes to practise on the credulity, or defeat the scepticism, of scientific men; but he is likely to be rather over-credulous himself upon the subject with which he is dealing. We imagine there must have been some feeling of disappointment at the result of the séance among those present: they had come to see something mysterious and inexplicable; they departed after witnessing a few performances, which can be explained—whether correctly or not—upon a simpler hypothesis than that put forward in the phrase "thought-reading." Now that the real meaning of mesmerism, stripped of all the delusions and trickery which so embarrassed it, has been revealed by the strictly physiological study of hypnotism, we are bound to look for simple physiological explanations for such "powers" as those originally claimed for Mr. Bishop; and it does not detract from the interest, although it may rob them of the mystery, attaching to such manifestations, to regard them solely in that light.

COVENT GARDEN MARKET.

THE inconveniences resulting from the overcrowded and dirty condition of Covent Garden Market and its approaches are well known to the general public who have occasion to visit it, but only those who live in the immediate neighbourhood can form an adequate conception of the filth and smells and the general unsavouriness of the place and its surroundings. A correspondent writing to us on the subject complains that a few days since a cart loaded with manure from the purlieus of the market upset in the street and discharged the whole of its contents into the area of his next door neighbour. Unpleasant as this catastrophe undoubtedly was, it would have called for no comment on our part had not our correspondent informed us that the cart in question was not a muck cart proper, but a market garden waggon used for bringing up cabbage and green vegetables from the country, and was taking back a return load of manure. The practice of thus conveying fresh vegetables and manure alternately in the same cart is as disgusting as it is dangerous. There can be no doubt that a considerable amount of the filth encrusted on the interior of these carts gets rubbed off and injures the vegetables by depriving them of their freshness and natural flavour, if it does not actually impart to them a *soupçon* of stable and street droppings. The attention of the sanitary authorities ought to be called to this state of things, and a reform effected in this as well as other details concerning the management of the market generally. It is well known that emanations from decomposing animal and vegetable matter are the inciting, if not the efficient, causes of septicæmia and blood-poisoning, the bane and peril of surgical practice. Nevertheless, we hear with amazement that it is seriously proposed to establish a special hospital for "stone" cases in close proximity to this hot-bed of disease. Lithotomy, lithotrity, and the whole series of operations for the treatment of stone are, *par excellence*, the surgical procedures which are exposed to the gravest risks, and require to be carried out with the most elaborate precautions to secure a pure atmosphere and innocuous surroundings. Special hospitals are bad anywhere and everywhere, but if it were desired to name the worst possible site for an institution of that class, it would be difficult to select one more insalubrious than the vicinity of Covent-garden; not to mention the fact that this neighbourhood is one of the noisiest in London, sleep at night being practically impossible. Who can be the responsible promoters of this new venture?

THE ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

PROFESSOR DE CHAUMONT has presented a report to the Special Committee of the Royal Portsmouth, Portsea, and Gosport Hospital, on the sanitary condition of the building, which shows it in a light even worse than that exhibited by Colonel Percy Smith, R.E., in the report by that gentleman we referred to a short time ago. According to Professor de Chaumont, the state of the hospital is so bad that any attempt to improve the present building would, in fact, be a waste of money. Site, general arrangement, particular details, drainage, &c., all seem to be irredeemably bad. "The question of rebuilding the hospital should," says Dr. de Chaumont, "be at once taken into serious consideration, for although some useful remedial measures may and ought to be carried out in the meantime in the present building, it is hopeless to expect that it can be made a good hospital in the proper acceptation of the term." The details given amply confirm this conclusion, and throw considerable doubt upon the advisability of any tinkering being attempted even for the temporary improvement of the building. The remedial measures suggested pending more radical changes simply serve to show that the radical changes should have the first, if not the sole, consideration.

TRICHINÆ AND TRICHINOSIS.

THE official report prepared for the United States' Government by Dr. W. C. W. Glazier, of the Marine Hospital Service, is on the whole somewhat disappointing. If it have for one object to set before the American public a complete and trustworthy account of trichinæ and trichinosis, it has also for another to make known the actual condition of the prevalence of parasitic disease of this nature in the United States, and to disabuse certain European countries of the exaggerated notion that has recently possessed them of the degree of prevalence of trichinosis among American swine. The first object has been very fairly attained by Dr. Glazier in the detailed account he gives of trichinæ and trichinosis, chiefly taken from German sources; the second is very imperfectly dealt with. He gives a table of the various accounts of trichinæ occurring in man which have been published in the United States, and presents a summary of the reports from pathologists in different parts of the States, which justify the inference that trichinosis in the human species is by no means commonly known in America; but he supplies no definite information upon the prevalence of the disease among the United States' swine, which is the question that most interests us on this side of the Atlantic, and which has given rise to so much uneasiness both in this country and on the continent of Europe. The report generally points to the importance of a thorough investigation of the subject in relation to swine in the United States.

EARL GRANVILLE ON THE BROWN INSTITUTION.

IN his opening remarks after the presentation of degrees at the University of London, on Wednesday last, Earl Granville made a graceful allusion to the loss sustained by the University in the election of the Superintendent of the Brown Institution, Dr. Greenfield, to the important chair of Pathology at Edinburgh University, and congratulated the University upon the appointment, remarking that London, perhaps, might some day have the pleasure of conferring similar honour upon an Edinburgh graduate. He referred in warm terms to the great and important labours effected at the Brown Institution since its foundation, ten years ago, by Professor Burdon Sanderson, Dr. Klein, and Dr. Greenfield, and held that these results more than justified the step taken by the University in accepting the Brown bequest, and undertaking to carry out its provisions. Passing from the scientific work of the institution, which had been so fruitful, Earl Granville remarked upon the benefits it had conferred as a hospital for animals, upwards of three thousand having been treated there during the past year.

ROYAL UNIVERSITY OF IRELAND.

THE pecuniary endowments proposed by the Senate of the new university are extremely liberal, more especially as regards the Fellowships. Independent of the various exhibitions offered, it is suggested by the framers of the scheme that twelve scholarships of the value of £50 each shall be allocated each year for competition—viz., four in classics, four in mathematics, and four in modern literature. They will be tenable for three years, and will be open to all students who at the Matriculation Examination next preceding the Scholarship Examination shall have gained honours in those subjects respectively. As regards the Fellows, the scheme proposes that they shall number forty-eight, the salary of each, if he be not also a Fellow or Professor of some other university or college attached to a university or college endowed with public money, being fixed at £400; while should he be in receipt of a salary from another university or college as Fellow or Professor, then he shall receive such sum annually as, with his other salary, shall amount to £400 a year. Each Fellow shall hold office for seven years. There shall be also fourteen Junior Fellowships, tenable for seven years.

BLEEDING AFTER TOOTH EXTRACTION.

IN another column Dr. Prickett draws attention to a subject of considerable interest—namely, the evil occurrence of, and the consequences resulting from, prolonged bleeding after tooth extraction. The Dentists Act, having thrown open the practice of dentistry in all its branches, together with all that can be comprised under that term, has done much to enlarge the source of danger to which our correspondent refers. Cases have been brought under our notice in which very grave results have supervened on the hæmorrhage from the socket of a tooth which has been "dragged out" of its place by a non-surgical dentist. The public will do well to be warned of the peril which may ensue if bleeding after tooth-drawing is neglected. Sufferers who have made the mistake of not in the first instance applying to a fully qualified surgeon for the relief of toothache should at least be prompt in securing the services of a competent practitioner when hæmorrhage begins.

THE FARMYARD IN THE STREETS.

SINCE the week before last a large quantity of straw, daily increased by horse droppings, has been lying where Grosvenor-street is crossed by Davies-street. The decomposing vegetation, wetted by the rain, and warmed into chemical activity by the sun, is blown about by the east wind into the neighbouring houses, the inhabitants of which thus enjoy the advantage of inhaling the odours of the farmyard without the trouble of leaving the West-end at the height of the season. They owe this accommodation to the authorities of the parish of St. George's, Hanover-square, who, however, if the arrangement be harmless, are somewhat inconsistent in one of the sanitary hints which they freely circulate—"Empty dustbins weekly, and keep them covered, but do not throw vegetable matter into them—better burn it." Is the medical officer of health out of town?

THE EDINBURGH GRADUATES' CLUB.

A LARGE company assembled at the dinner of this club on Wednesday, May 11th. The chair was occupied by Professor Masson, who humorously discussed the mission of Scotchmen in England. Amongst the visitors were Lord Rosebery, Mr. Woolner, R.A., Professor Macfarren, J. A. Campbell, Esq., M.P., J. Erichsen, Esq., Col. Arthur, Alderman Ellis, and Alderman Glover, J.P. Dr. Lyon Playfair proposed the health of Lord Rosebery, who, in the course of his reply, referred to the Commission on the Medical Acts, and said that he had declined taking part in the work from the somewhat delicate nature of his position as Rector of two Scotch universities. He spoke favourably of Lord Camperdown as chairman.

THE LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

ARRANGEMENTS have been completed with University College, Liverpool, by which the School of Medicine in connexion with the Royal Infirmary from henceforth becomes its Medical Faculty. The school will be represented on the Senate of the College by the Lecturers on Medicine, Surgery, Anatomy, and Physiology, who for the future will be designated Professors. The College has acquired the site and grounds of the Lunatic Asylum connected with the Royal Infirmary, which is about to be closed, and as soon as the necessary adaptations are completed the College will be opened.

THE ROYAL (MEDICAL ACTS) COMMISSION.

NO formal summons for a meeting of the Commission has, we are informed, yet taken place, but it is probable that a meeting will be held in about ten days. The address of the Medical Acts Commission is 2, Victoria-street, S.W. The secretary is John White, Esq., Barrister-at-law.

WE regret to announce the death of Surgeon-Major Charles Haines, Army Medical Department. Mr. Haines left Bombay as a passenger in H.M. troopship *Crocodile*, in very bad health, suffering from phthisis pulmonalis, and expired on board ship the day after the vessel reached Portsmouth. Mr. Haines obtained his commission as an assistant-surgeon in September, 1863, and was promoted to the rank of Surgeon-Major in April, 1876.

A CASE of alleged metallic poisoning has been made the subject of judicial inquiry at Stone, Staffordshire. The facts brought to light at the examination of the accused are of some medico-legal interest, and may call for comment on a future occasion.

FOR the first time in its annals our leading Medical Society met and adjourned without having any scientific material for discussion. On Tuesday last this unique event happened to the Royal Medical and Chirurgical Society, and it betokens either that the Fellows are becoming tired of writing papers, or that their whole energies in this direction are absorbed by the forthcoming Congress. The latter view is, we trust, the correct one; and the former will, no doubt, speedily be dispelled by an increased amount of vigour on the part of the Fellows, who will have the advantage of securing an early day for the reading of their papers.

THE annual dinner of the officers of the Army Medical Department will, we understand, be held at the Inns of Court Hotel, Lincoln's-inn-fields, on Saturday, June 4th, under the presidency of Sir W. M. Muir, the Director-General. Officers intending to be present on the occasion should send their names to Surgeon-Major Clarke, Whitehall-yard.

THE *London Gazette* of the 6th inst. contains an Order in Council renewing for the term of five years, dating from May 23rd, the appointment of Mr. John Simon, C.B., F.R.S., and Mr. Thomas Pridgin Teale, F.R.C.S., as members of the General Council of Medical Education and Registration of the United Kingdom.

THE appointment of Dr. Fetherston, a member of the Senate, to a seat on the Council of the University of Melbourne, forms a subject of gratulation by the *Australian Medical Journal*. It appears that several attempts had previously been made to secure the return of a medical candidate, but without success.

THE *Echo* of Thursday says the fasting girl at Strathaven, in Scotland, having been threatened with incarceration in a lunatic asylum, began to partake freely of food yesterday morning. The medical men have their suspicions that she has been taking food all along.

THE Council of the College of Surgeons, at a meeting held on Thursday, elected Mr. Charles Sissmore Tomes, F.R.S., a Member of the Board of Examiners in Dental Surgery, in the room of Mr. Salter, resigned.

THE Governor of Gibraltar has appointed John H. Bryant, F.R.C.P. Edin., to take medical charge of the sick poor of the South District, in the place of Surgeon-Major A. Allan, M.D., resigned.

PROFESSOR GEGENBAUER, of Heidelberg, is reported to be suffering severely from blood-poisoning, the result of a wound incurred whilst dissecting.

DR. PAUL F. MUNDÉ, of New York, has been elected Professor of Gynæcology in Dartmouth Medical College, in place of the late Dr. Peaslee.

ROYAL INSTITUTION OF GREAT BRITAIN.—The following Vice-Presidents for the ensuing year were announced at the general monthly meeting, on May 9th, 1881:—Mr. William Bowman, Mr. Frederick Joseph Bramwell, Sir W. Frederick Pollock, Bart., Mr. William Spottiswoode, Mr. George Busk, Mr. Warren De La Rue, M.A., D.C.L., F.R.S., Secretary. Messrs. Frederick Arthur Crisp, Ernest Gye, and Samuel Armstrong Lane were elected members. Dr. John Tyndall was re-elected Professor of Natural Philosophy.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Stroud, Rural (*Gloucestershire*).—Dr. Partridge estimates the population in this district in 1880 at 29,320, and gives the birth-rate for that year as 28·1, and the death-rate as 17·2, per 1000 inhabitants. He has the following comments upon the deaths entered as "uncertified" in the register, in this instance forming 5·5 per cent. of the total number registered:—"We may fairly assume, when a death is entered on the register as uncertified, that the person has not been seen by a registered medical man, or has been in the hands of an unqualified person, or perhaps of some 'wise woman.' The stated causes of death in such cases are almost worthless, being the opinion of ignorant or incompetent persons, and where medical aid is not sought it is most likely the result of neglect on the part of the parents. So many premature births and convulsions in infants lead to the question, Are they the result of malpractice on the part of midwives? Or may not some be attributed to *abortifacients?* One unqualified practitioner who resided in this district has left, but no certificate was accepted from him as to the cause of death. That there are still some persons who practise without being qualified there is no doubt, and probably some of the uncertified cases have been treated by them. There is no lack of medical aid to be had, and persons dying without any, except in cases of sudden illness, is at least very suspicious, as I know that the parish surgeons are always ready to assist in time of need. These cases should be carefully inquired into by persons more competent to judge them than the ordinary policeman, whose knowledge of these things does not enable him to distinguish between a case of 'overlaying' a 'premature birth,' or a 'probable hydrocephalus.' An inquiry into the causes of death in uncertified cases, especially those of illegitimate children, by a competent person, would have a deterrent effect on those whose unnatural feelings lead them to neglect their own offspring, and who are too often glad to be rid of the trouble and expense attending the care of them." Dr. Partridge considers separately the sanitary condition and requirements of the several places entering into the rural district.

Tamworth, Rural (*Staffordshire*).—Dr. Herbert J. Faussett's report for this district in 1880 contains much of interest on its sanitary condition and administration. The population is estimated at about 14,000, and is distributed over an area of 40,000 statute acres. The birth-rate is given at 36·0, and the death-rate at 16·9 per 1000 inhabitants. He notes of diarrhœa among young children, prevalent in August and part of September, that "the disease appeared in a more virulent form within the area of the river district. There is little doubt," he adds, "that the exhalations arising from open drains, from ditches filled with stagnant sewage, and from ground sodden with repeated inundations of liquid sewage from a polluted river, contaminate the air with putrefactive ferments, which, when breathed in, originate disease in all those who from lowered health are unable to resist such potent influences." He attributes, moreover, some part in the production of diarrhœa to polluted water from shallow wells, and even from deep wells within the area of the river-bed. The following observations on floods in their sanitary aspect will be read with interest in view of the present proposition for legislation for the regulation of rivers. "The question of the prevention of floods is one which greatly concerns the health of those living in the neighbourhood of low-lying districts, liable to be flooded, over and over again, with water polluted with sewage and every description of filth. Rivers have hitherto been considered the natural recipients for all the sewage that can be turned into them. The Tame when it enters this district is already contaminated with sewage received in its course higher up, and it is also further polluted at various points within the district, more especially when it is at its ordinary level. When, however, the river is in a flooded condition, and receives, in addition to the sewage and solid refuse of towns and villages, the mud and detritus brought by each drain and streamlet, all this filth is washed over the lands for some hundreds of yards in width along its course. The owners and occupiers of any houses in these localities are exposed to all the dangers and losses derived from having the crops swept off the meadows, and the produce of their fields and gardens destroyed. Houses and premises are, in many places, flooded with this filthy polluted water, which makes them very unhealthy to live in, from the saturated state of the floors and soil, and from the foul exhalations arising therefrom. This terrible condition of affairs, which applies in a lesser degree to the lands flooded by the river Anker, is continually taking place, and must tell very unfavourably on the health and constitutions of the inhabitants in many ways, where so many hundreds of acres are so frequently under water; so many as sixteen times during the year. For, in addition to the great dangers to which human life is exposed, the injurious deposits left by the floods have done an immense amount of damage to the lands, which have become less fertile and nourishing, and at times positively injurious for cattle."

Shildon, Urban (*Durham*).—Mr. Fielden gives the birth-rate and death-rate for this district in 1880 as 31·6 and 19·3 respectively per 1000 inhabitants, the population being estimated at 10,000. Scarlet fever and measles were epidemic in the district during the course of the year, and Mr. Fielden observes that he generally found the cases occurred under circumstances where there was more or less neglect of sanitary precautions—to wit, wet or uncovered privies, uncemented, undrained ashpits, heaps of decaying matter lying near doorways in small yards, imperfectly trapped or constructed drains, &c. It is evident that there is no lack of work for the sanitary authority to do in this district, and it is somewhat disheartening to read that the recommendations of a special report prepared by the medical officer of health on the sanitary condition of the district should not have been attended to.

Worcester (*City*).—Dr. Strange's report for 1880 shows much that is gratifying in the sanitary condition of this city. It would appear that nuisances have markedly diminished in number, that the city water-supply is good, and the use of water from wells is being abandoned in all the closely built parts of the city, very few pumps being now in use. Further, the sewerage of the city is being extended where most needed, and amended where defects have been shown. The substitution of waterclosets for open privies is, moreover, being steadily carried out wherever the condition of the same permits of this being done. Worcester has a hospital for infectious diseases, which Dr. Strange states "continues to justify its establishment." The population is estimated at 35,200, and the birth-rate for 1880 was 33·22, the death-rate 20·0 per 1000 of the inhabitants. On a retrospect of the past seven years, Dr. Strange observes "the data presented, I think, will justify your authority in feeling satisfied that the great work of sanitary amelioration is being fairly and steadily carried out."

Saltley, Urban (*Warwickshire*).—Mr. W. G. Cresswell, in his report on this district for 1880, returns a general death-rate of 23·96 per 1000 of the population; this rate, as well as the mortality from zymotic diseases, being higher than in either of the three previous years. This increase of mortality is assigned to the large number of deaths from diarrhœa, and upon this subject Mr. Cresswell observes: "The fault lies with the mothers and nurses; not, let it be understood, in their wilful neglect, but rather in their not knowing the principles which ought to govern the feeding of, and otherwise caring for, their young charges." Mr. Cresswell proposes to combat this ignorance of mothers and nurses by issuing a small pamphlet on infant nurture. The prevalence of diarrhœa was in the autumn, and earlier in the year the district suffered from scarlet fever. It would appear that a system of sewerage is being carried out in the district.

Reading, Urban (*Berkshire*).—Dr. Shea's report for 1880 shows that the sanitary authority of this urban district are not unmindful of their duties, and that they are fortunate in possessing a medical officer of health peculiarly able to advise them rightly on the medical aspects of these duties. Dr. Shea's report is an excellent example of what a report should be in districts of this class. Reading in 1880 had a population estimated at 41,500, and its death-rate for that year is given as 19·6 per 1000 inhabitants—a somewhat higher death-rate than obtained in the previous year. The birth-rate for the same period was 37·8 per 1000. The augmented death-rate for 1880, and particularly the higher rate from zymotic diseases, are attributed to the unusual mortality that occurred last autumn from diarrhœa, and to the fatality of scarlet fever and whooping-cough during the earlier part of the year. Dr. Shea has interesting observations on the several forms of zymotic disease which appeared in the urban district during the year, but we must limit our attention to his observations on diarrhœa, and of these we would reproduce the following. He tells us that in the year 1875 diarrhœa was extremely fatal in Reading, though not so fatal as in 1880. To this he adds that, "In both these years, 1875 and 1880, there was *a very wet July, followed by a hot August, and when such a sequence prevails, summer or autumnal diarrhœa prevails.*" Further, he says that so far as the limited data at his command go, "it would appear that the mean temperature and mean rainfall afford no guide, but that a certain relative sequence must be established—(1) a wet month, then (2) a hot and comparatively dry one. If these occur the atmosphere is in a condition to favour the rise of soil and other exhalations, and to favour the appearance of diarrhœa from these causes, and by setting up incipient fermentation in articles of food and drink, &c. No doubt overcrowding, foul air, and bad sanitary arrangements favour the development and fatality of summer diarrhœa, and require to be closely watched and guarded against; at the same time the natural tendency that is created in hot weather and hot climates to throw an excess of elimination of bile on to the liver, and so induce bilious diarrhœa, must not be forgotten."

SMALL-POX HOSPITAL ACCOMMODATION IN THE METROPOLIS.

We are glad to have to state that the Metropolitan Asylums Board have seen their way at least to a partial solution of their difficulty as to providing further hospital accommodation for cases of small-pox in the metropolis. They propose to give up the Homerton Hospital solely to small-pox, dispersing cases of "fever," which under ordinary circumstances would be sent there, in their other hospitals. Further, they are now forming on an extensive estate they have at Darenth, in Kent, where the Board has a very large imbecile asylum, a tent hospital for convalescents from small-pox, and which will accommodate at least 300 patients. The Board propose to take the whole responsibility of transferring convalescents from London hospitals to Darenth, which is sixteen miles from the metropolis by the high road—a drive in an ambulance which convalescents may well undergo without risk to their health. Thus the Board, by its arrangements at Darenth and Homerton, will set free for acute cases of small-pox some 500 beds.

THE NATIONAL HEALTH SOCIETY AND VACCINATION.

The National Health Society has issued an admirable little pamphlet for general distribution among the public, entitled "Facts Concerning Vaccination for Heads of Families." This pamphlet, it is stated, has been revised by the Local Government Board, and this Board has further sanctioned the repayment out of the metropolitan common poor fund the expense of printing twenty thousand copies, and of their distribution from house to house in the Poplar Union by thirty persons appointed by the local Guardians for this duty. We congratulate the Society upon its admirable little pamphlet and excellent action in this matter, and we hope the example of the Poplar Guardians will be largely followed in the metropolis. We trust also that large employers of labour and all who are interested in controlling the present epidemic will give to this pamphlet as much publicity as possible. The society are prepared to supply the pamphlet from their office, 44, Berners-street, W., at the cost of printing—namely, 18*s.* per 1000.

A case of small-pox has been imported into Bristol from London, and Dr. Davies, the medical officer of health, has thought it desirable to suggest to the Sanitary Authority the advisability of taking special measures of precaution as to vaccination. The patient is isolated in the sanitary hospital. At a recent meeting of the Authority, Dr. Davies reported upon some deposits of chemical refuse in the suburbs of the city. It appears that houses were built on a part of this refuse, which, although objectionable, does not appear to be unhealthy, and, indeed, has one negative advantage—namely, no drinkable water can be obtained from it, and so the residents on it are saved from the danger of drinking water from shallow wells and its liability to convey typhoid.

Mr. Dodson, the President of the Local Government Board, having consented to receive a deputation from the Poor Law Medical Officers' Association, on the subject of compulsory superannuation, has fixed Tuesday the 17th instant, at 2 P.M. precisely, at the Board's Offices, Whitehall. It is to be hoped that all Poor-law medical officers and others interested in this question will make an effort to attend, and that they will use what influence they possess to induce such M.P.s as they may happen to know to be present in support of the objects of the Association.

A case was recently heard before Mr. Justice Stephen, in which damages were claimed from the Manchester Corporation for injury done to a house from the bursting of one of the Corporation's sewers during a storm. The learned judge held that the Corporation were bound to see that their sewers were in a sound condition, and as they had failed to do this, they were liable to damage; but he stayed execution to give the Corporation opportunity to move for a new trial.

The Local Government Board have had to direct the attention of the Prescot Guardians to the exceptional entry, in a list of seventy-five children in a vaccination return, of eight reported as "insusceptible of vaccination." The Board have requested that the certificates of these cases shall be forwarded to them, cases of insusceptibility being of rare occurrence.

A milk-dealer has been fined at Warrington for not having notified to the Sanitary Authority a case of scarlet fever, a child in her house, which she attended and nursed while pursuing her business. The child died, but no medical man was called in until the day of death.

In a case preferred before the Master of the Rolls, for an injunction against a small-pox hospital erected by the Fulham District Board of Works in Little Wormwood Scrubs, the application was refused, but leave given to the appellants to serve motion at a later date, and produce further evidence.

No less than eleven district boards and vestries in different parts of the metropolis have made overtures to the Poplar District Board for accommodation for small-pox cases in their infectious disease hospital at West Ham.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a further decline last week, and was lower than in any previous week of this year. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5205 births and 2929 deaths were registered last week. The births exceeded by 19, whereas the deaths were so many as 328 below, the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had been equal to 22·9, 22·0, and 21·2 in three preceding weeks, further declined last week to 20·1. The lowest rates in the twenty towns last week were 12·4 in Brighton, 14·4 in Leicester, 16·2 in Sunderland, and 16·5 in Birmingham. The rates in the other towns ranged upwards to 22·1 in Liverpool, 23·2 in Hull, 24·3 in Nottingham, and 28·5 in Wolverhampton. During the first five weeks of the current quarter the death-rate in the twenty towns averaged 21·7 per 1000, against 24·3, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 410, 382, and 375 in the three previous weeks, rose again to 410 last week; these included 105 from measles, 89 from small-pox, 76 from whooping-cough, 56 from scarlet fever, and 31 from fever, principally enteric. The annual death-rate from the principal zymotic diseases averaged 2·8 per 1000 in the twenty towns, and ranged from 0·0 and 0·4 in Brighton and Hull, to 3·4 and 3·7 in Portsmouth and London. Measles showed the largest proportional fatality in Sheffield, Bristol, and London, scarlet fever in Wolverhampton and Hull, and whooping-cough in Sheffield and Salford. The highest death-rate from fever was again recorded in Liverpool. The 22 deaths referred to diphtheria in the twenty towns included 12 in London and 4 in Portsmouth. Small-pox caused 94 more deaths in London and its outer ring of suburban districts, and 1 in Oldham; whereas no fatal case was recorded in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 963 and 942 at the end of the two preceding weeks, rose to 1093 last week; this is the largest number that has been under treatment in these hospitals since the epidemic of 1871–72. The new cases admitted to these hospitals were 363 last week, against 244, 227, and 178 in the three previous weeks; the Homerton Fever Hospital has just been opened for small-pox patients, which accounts for the large increase in the number of admissions last week.

The deaths referred to diseases of the respiratory organs in London, which had been 395, 338, and 328 in the three preceding weeks, further declined to 297 last week, and were 17 below the corrected average number in the corresponding week of the last ten years; they included 152 from bronchitis and 99 from pneumonia. The annual death rate from lung diseases, exclusive of phthisis, was equal to 4·2 per 1000 in London last week; while the rate from the same diseases was equal to 4·6 in Liverpool.

The causes of 89, or 3·0 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. This proportion of uncertified deaths did not exceed 1·6 per cent. in London, whereas it averaged 4·4 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth, Norwich, or Plymouth; while the proportions of such deaths were largest in Sunderland, Oldham, Leeds, and Hull.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half persons, the annual death-rate last week was equal to 21·4 per 1000, against 23·5, 22·1, and 21·2 in the three preceding weeks; this rate exceeded by 1·3 the average rate prevailing in the twenty English towns. The rates in the eight Scotch towns ranged from 17·3 and 20·0 in Leith and Edinburgh, to 25·3 and 31·8 in Perth and Paisley. With reference to the recent high death-rate in Paisley, it is noted in the Registrar-General's return that it is probably over-stated by an under-estimate of the present population, as the recently enumerated numbers have not yet been revised and brought into use. The deaths referred to the principal zymotic diseases in the eight towns, which had been 82, 69, and 64 in the three preceding weeks, were again 64 last week; they included 17 from diarrhœa, 12 from "fever," 11 from whooping-cough, 11 from scarlet fever, 8 from diphtheria, 5 from measles, and not 1 from small-pox. The annual death-rate from these zymotic diseases averaged 2·5 per 1000 in the eight towns, and was 0·3 below the average rate from the same diseases in the twenty English towns. This zymotic death-rate in the eight Scotch towns ranged from 1·0 and 1·3 in Aberdeen and Greenock, to 2·9 and 3·2 in Glasgow and Paisley. The deaths referred to diarrhœa showed a further increase upon recent weekly numbers, and were equal to a considerably higher death-rate than that attributed to the same cause in the English towns. The deaths from "fever" (including typhus, enteric and simple continued), which had been 7, 11, and 7 in the three preceding weeks, rose to 12 last week, of which 7 occurred in Glasgow, 2 in Edinburgh, 2 in Dundee, and 1 in Paisley; the annual death-rate from this cause was equal to 0·48 per 1000, and was more than twice the average rate from fever in the twenty English towns. The 11 fatal cases of whooping-cough showed a marked further decline from the numbers in recent weeks, and included 4 in Glasgow, 2 in Edinburgh, and 2 in Paisley. The 11 of scarlet fever, however, showed an increase; 5 occurred in Glasgow, 4 in Edinburgh, and 2 in Dundee. Of the 8 deaths referred to diphtheria, 7 were returned in Glasgow; as were all the 5 fatal cases of measles. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had steadily declined from 163 to 116 in the four preceding weeks, rose again to 140 last week, and were equal to an annual rate of 5·5 per 1000, while the rate from the same diseases in London did not exceed 3·6.

HEALTH OF DUBLIN.

The rate of mortality in Dublin showed a further decline last week, and was lower than in any previous week of the year. The annual death-rate in the city, which had been equal to 32·6 and 30·7 per 1000 in the two preceding weeks, further declined to 27·5 last week. During the first five weeks of the current quarter the death-rate in the city averaged, however, 30·1 per 1000, against 21·9 in London and 20·9 in Edinburgh. The 176 deaths in Dublin last week showed a further decline of 20 from the numbers in the two previous weeks, and included but 8, or less than 5 per cent., which were referred to the principal zymotic diseases, against 9 and 19 in the two previous weeks. These 8 deaths from zymotic diseases included 3 from fever (typhus, enteric or simple), 2 from whooping-cough, one each from small-pox, measles, and diphtheria, and not one either from scarlet fever or diarrhœa. The annual death-rate from these zymotic diseases was equal to 1·3 per 1000, while the rate from the same diseases was 3·7 in London and 2·4 in Edinburgh. The deaths referred to fever in Dublin, which had been 2 and 14 in the two preceding weeks, declined again to 3 last week; the annual death-rate from fever, however, was more than twice as high as the average rate from the same cause in the twenty large English towns. The fatal case of small-pox was the first recorded within the city since the end of March. The deaths referred to the other principal zymotic diseases were again satisfactorily few. The deaths of infants and of elderly persons differed but slightly from the numbers returned in the two preceding weeks.

VITAL STATISTICS OF TRINIDAD.

The Registrar-General of Trinidad has recently presented his report upon the vital statistics of the island during 1880, which contains some points of interest, although its statistical information is of a very meagre description. The population of the island is, for the purpose of this report, estimated at 140,000; but the estimate, it appears, is calculated by the addition of the excess of births over deaths since 1871 to the population then enumerated, without taking any account of the increase by immigration. This immigration, a considerable portion of which consists of coolies from India, has probably, it is said, raised the population to about 184,714, which number Sir S. Freeling, the Governor, anticipated would be enumerated in the course of a few days. With such an opinion of the present population of Trinidad it is not easy to account for the adoption of 140,000 as the basis for calculating the vital statistics for 1880. It is evident that the population of the island has rapidly increased in recent years, as only 109,638 persons were enumerated in 1871. In 1880 the births registered were 5346, against 3842 in 1871; and the deaths were 4010, showing an excess of births over deaths equal to 1336. The birth- and death-rates are given as 38·2 and 28·6 per 1000 respectively; both, however, are probably overstated by an under-estimate of the population. The mean death-rate for the ten years 1871–80 is given as 33·3 per 1000, and even assuming that this is somewhat overstated it is evident that the mortality is high enough to give undeniable evidence of insanitary conditions. It is disappointing to find that the report gives no information except the bare numbers of births, deaths, and marriages registered. Without tables showing the causes of death and the ages of the decedents it is impossible to form any sound conclusions as to the causes of the excess of mortality in the island.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

SCARLET FEVER AT HALIFAX.

Dr. Ballard, who has been engaged in an investigation of the recent unusual prevalence of scarlet fever in Halifax, met the Town Council there a few days ago and submitted to them the results of his inquiry to that date. In the main it would appear that these, particularly in regard to an infected milk-supply, have confirmed the results obtained by the previous investigations of Dr. Ainley, the medical officer of health, and he gave one example in this direction which we do not think has been made public before. One townsman during the outbreak had an evening party, and of thirty-five people who met there twenty-six were soon after attacked with scarlet fever or sore-throat. Dr. Ballard believed that this singular spread of the disease had to do with the distribution of infected cream. He animadverted upon the insufficient action taken by the sanitary authority in presence of the disease, and noted especially the want of proper supervision of inns where scarlet fever was present. He mentioned one instance especially where children suffering or convalescent from the disease were allowed to run about among the visitors without any check. He remarked also upon the action of the medical men in not sending reports to the medical officer of health of cases of scarlet fever coming under their notice, thus sacrificing the general good of the community to the professional feelings which had made Dr. Ainley's appointment so objectionable to them. But we apprehend that the profession in Halifax is as the profession elsewhere, and it was not to be expected that official success could be attained in the presence of such an anomaly as the appointment of a "homœopathist" to confer on health matters with the local practitioners of scientific medicine.

THE MILK EPIDEMIC AT ABERDEEN.

A Commission of Inquiry, appointed under the Public Health Act, has been held at Aberdeen into the curious outbreak of sickness which has recently prevailed in the town, apparently in connexion with the distribution of milk from a particular source. The Commissioners were Mr. Andrew Rutherford, advocate, Edinburgh, and Dr. H. D. Littlejohn, medical officer of health of that city, Mr. Charles Duncan, procurator fiscal, acting as their agent in the inquiry. A good deal of evidence was given in the course of the inquiry, but little was added to the information which has been already published in THE LANCET. The newer matter chiefly related to a series of microscopical examinations of the suspected milk conducted by Prof. C. Ewart, and which went to show that it contained numerous micrococci and bacteria spores. He believed that these microscopic organisms constituted a morbid element in the milk, but he had not completed his investigations regarding them; but so far as he had gone the results indicated that they were the cause of the disease. The Commissioners sat three days, and the results of their deliberations on the evidence submitted to them will be embodied in a report to the Board of Supervision.

Dr. W. B. Carpenter has contributed to the columns of *The Times* a letter, giving the results of his personal experience of vaccination and small-pox, and the question of vaccination generally. This statement of experience will, it may be hoped, cause anti-vaccinationists to pause in their suicidal course, and act as an antidote to the pernicious nonsense which they have scattered broadcast. Dr. Carpenter adds nothing new to our knowledge of the question, but he confirms in a most instructive and ample fashion the current views as to vaccination and revaccination as protective against small-pox.

THE SERVICES.

The *Bombay Gazette* of the 21st April publishes an announcement that Brigade-Surgeon Lundy, Army Medical Department, attached to the 2-22nd Regiment at Allahabad, had committed suicide by poison on the 19th of that month. On inquiry at the War Office we find that up to date no confirmation of the report has been received there.

Surgeon-Major A. Stephen, M.B., Bengal Medical Service, has been appointed Statistical Officer to the Government of India in the Sanitary and Medical Departments from the 18th November, 1880, in succession to Surgeon-Major J. L. Bryden, M.D., deceased.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Charles John Fennell has been placed on the retired list of his rank from May 9th.

The following appointments have been made:—Staff-Surgeon Thomas O'Sullivan, M.D., to the *Mutine*, when commissioned; Staff-Surgeon William H. Colahan, M.D., to the *Revenge*, vice Surgeon M'Swiny; Surgeon William B. Drew, to the *Cockatrice*, when commissioned; Surgeon Myles O'C. M'Swiny, to the *Wrangler*, when commissioned. Staff-Surgeon H. Clerke, to the *Duncan* (in lieu of a surgeon), vice O'Sullivan; Surgeon Christopher Pearson, to the *Boscawen*, additional for the *Seaflower*, during cruising season; Staff-Surgeon Samuel Bamfield, to the *Implacable*, vice Campbell.

AT Highgate Police Court this week a first-class attendant at Colney Hatch Asylum was fined £2 and costs for kicking a patient on the side.

UNIVERSITY OF LONDON: CONVOCATION.

THE PRELIMINARY SCIENTIFIC M.B. EXAMINATION.

A MEETING of Convocation of the University of London was held on the 10th instant. Dr. Storrar, Chairman, presiding. Mr. Allen was re-elected Clerk of Convocation.

Dr. POORE moved the adoption of the following resolution, recommended by the Annual Committee: "That it is desirable that the Preliminary Scientific (M.B.) Examination be held twice in the year—viz., in March and August; and that it be optional for candidates to take up either all four subjects at once, or two at a time, such subjects to be previously specified by them." A previous resolution had been passed unanimously by the House in January, 1880, and had been considered by the Senate. In that resolution it was recommended that the First M.B. Examination should also be held twice annually; but this was not so important as the Preliminary Scientific Examination. The Senate, with its usual readiness, had carefully considered the question, and referred it to an influential committee, and now awaited a further opinion of Convocation on the subject. The resolution was aimed at giving every facility to candidates without lowering the standard of the examinations. London afforded great opportunity for the study of medicine, greater than any place in the world, and yet, in order to obtain degrees, its students went to Edinburgh to graduate. The "paltry numbers" (the phrase used by a distinguished graduate, Dr. Bristowe, in a letter to the Chancellor) who take the London medical degrees were accounted for by the time and consequent expense entailed upon students who, matriculating in January, were unable to present themselves for the Preliminary Scientific Examination till the following July twelvemonth; and who, failing to pass the latter, had to spend another year before being able to make a second attempt. The clamour which had been raised in some quarters against the degrees was natural but unjustifiable; still the University was bound to give every facility if it would maintain its place and take away just grounds of complaint. The reasons in favour of doubling the examinations were shortly these. That the number of students seeking degrees is on the increase. That it would shorten the time required to take a degree, much time being at present used before the student can enter on his proper medical studies. It would be an act of justice to those who fail in only one subject—no inconsiderable number,—at present most hardly treated. Moreover, the increase in the numbers of those who take the London degrees would be an advantage to the professors, to the students, the university, and the teachers of science. The Edinburgh professorships were sought after because of their great value, and if London students were encouraged to go in for the science examinations, the teachers would reap the benefit. The objections raised to the change depended mainly upon the abolition of the Honours Examination, which was said to be a necessary outcome of the change. The objections were not raised by the students. They were as follows. That by doubling the examination the courses of study as at present prescribed would be deranged; but that was not an insuperable difficulty, and, besides, did not concern the University, which had only to consider the needs of its own graduates. It was said that it would increase the difficulties of examiners and render the obtaining of examiners a matter of difficulty; but surely this could not be seriously maintained. Then, there was the abolition of Honours, to which another resolution was devoted. The final clause of the resolution was proposed to meet the views of those who held that some students could carry two or three subjects in their heads at one time, but not four.

Dr. CURNOW seconded the resolution, and directed especial attention to the fact that the Senate had received replies to a request it had made to the deans of the metropolitan medical schools upon the desirability of this change, and that 13 out of 15 were in favour of it. This showed that those who were directly concerned in medical education, and who knew where the student's difficulties lay, were of opinion that the facilities asked for should be granted.

Dr. G. C. TAYLOR opposed the resolution, maintaining that it was of the greatest importance that nothing should be done to lower the standard of efficiency required of medical graduates.

Mr. R. T. **Roberts** moved an amendment, leaving out all the words after "August"; as, if the clause stood, it would not be justified in that examination alone, but would have to be applied to Matriculation also.

Mr. **Tidmarsh** seconded the amendment, on the ground that the clause in question was contrary to the spirit of the University.

Mr. **Tylor** questioned whether the Preliminary Scientific Examination should be retained. It was instituted in 1861, and contained few subjects really essential to medical graduates, to whom Greek was even more necessary.

Prof. **Thistleton Dyer** said the change proposed was one which was held to be of great moment by the executive officers of the examination. The argument that a great number of candidates presented themselves did not accord with the further statement by Dr. Poore, that the degrees were not sought after. The number of candidates was not larger than could be dealt with at the examination, and he considered the resolution as a subtle attempt to reduce the standard of these examinations. He could not see how multiplying examinations would afford facilities to decently prepared candidates, but only to those who would be encouraged to come up on the chance of passing, knowing that if they failed they could appear again after a short interval. The Edinburgh professorships were valuable because there was one great medical school in that city, and for no other reason. The resolution would have the effect of encouraging private study, to the detriment of teachers. He did not think much stress could be laid on the answers furnished by the deans of the medical schools. No doubt occasionally hard cases of rejection on simple subjects did occur, but such cases might be met if the Board of Examiners advised that a candidate so rejected might be examined in that subject only on his second appearance.

Dr. **Pye-Smith**, as one of those who signed the memorial to the Senate, gave his reasons for opposing the resolution if amended as proposed. In the course of his remarks he said all were agreed as to the desirability of affording facilities for obtaining medical degrees by a larger number of candidates, but care should be taken that the value of the degrees be not interfered with. It was undesirable to make the degrees easy, and he was of opinion that the examinations ought to be such as a majority of men could not pass, and he did not see how the taking of a degree could be facilitated without injuring its value. The idea of having two examinations annually was open to several objections. Twelve months was not too long for preparation for the Preliminary Scientific Examination, which stood on a footing quite distinct from the Matriculation. The latter dealt with subjects studied during the whole of school life, whereas the former embraces subjects to which only one year has been devoted. Holding the examination twice a year would practically lead to the inference that it was an examination which could be passed after six months' study, and would be a direct incitement to cramming. Therefore, unless the amendment were rejected, he would not vote for the resolution, which without the saving clause would be an unmitigated evil.

Dr. **Coupland** pointed out that the difficulties imagined had not been found by those other universities which held two similar examinations for their medical degrees more than once a year; that it would be easy to insist upon a year's interval elapsing between the passing of Matriculation and the Preliminary Scientific M.B.; that the value of the examinations did not depend upon their number, but upon their nature; and that the chief point which had been raised—viz., the disarrangement of class instruction—was not so great as not to be overcome. Students preparing for these examinations did not require lengthened courses, embracing the whole of the subjects (e.g., chemistry), and practically this was admitted in most medical schools where classes were instituted for the Preliminary Scientific Examinations, such classes not commencing before January, the examination taking place in July. The resolution was aimed at relieving a recognised grievance on the part of medical students.

Dr. A. W. **Bennett** was surprised that at any medical school in London the attempt should be made to compress the science instruction within six months. He supported the views of Dr. Pye-Smith, and urged that if the amendment were carried those who were interested in the value of this examination should vote against the resolution.

Dr. **Hilton Fagge** said the question was that a student at present had often to wait sixteen or eighteen months between the Matriculation and Preliminary Scientific Examination. He was not particularly anxious that only two subjects should be given; but at present it was a fact that the best men were excluded. He thought teachers overestimated the amount of work done through lectures; the student read books independently of them.

Mr. **Magnus** thought Dr. Pye-Smith's position an illogical one, and he did not see, if the resolution were carried and the change effected, any necessity for the schools to alter their courses.

Mr. **Spratling** said that science was becoming more and more taught outside medical schools, so that their convenience was not of moment.

Dr. **Poore**, in reply, said he did not feel strongly about the amendment. Professor Dyer had no right to say that this was a subtle attempt to lower the standard of the examination, and "cramming" was impossible in such a practical examination as the Preliminary Scientific.

The amendment was then put and declared carried; and the resolution as amended was also carried by a large majority.

Dr. **Poore** moved, and Dr. **Curnow** seconded, a resolution, "That instead of Honours in special subjects (in the Preliminary Scientific Examination) a general list be made at each examination as at Matriculation." This was opposed by Professor Dyer, but was carried with but few dissentients.

A discussion then took place on the desirability of an Act providing for the registration of teachers, but this and further resolutions bearing on the same subject and upon Sir John Lubbock's Bill were eventually passed over.

Mr. A. P. **Hensman** moved the following resolution:—"That it is just and desirable that women who are graduates of this University, and of the requisite standing, should be entitled to become members of Convocation, and to vote at the election of the Member of Parliament of the University," which was seconded by Mr. Nesbitt.

To this an amendment was moved by Mr. A. McDowall, seconded by Dr. A. W. Bennett, "That female graduates be admitted to Convocation."

The adjournment of the debate was moved by Mr. Tylor and seconded by Mr. Morris. It was supported by Mr. Hensman, and on being put to the vote was carried.

The House then adjourned.

INTERNATIONAL MEDICAL CONGRESS.

By the change in the presidency of the College of Physicians Sir W. Jenner becomes *ex officio* chairman of the General Committee of the Congress, a post the duties of which have up to the present time been so ably discharged by the chairman of the Executive Committee, Sir Risdon Bennett. Owing to a deficiency in space for the accommodation of the sections dependent on the fact that the honours' examinations of the London University will necessitate a portion of the buildings in Burlington-gardens being reserved, the Executive Committee have had to look for fresh meeting places, and these have been generously placed at their disposal by the authorities of the Royal School of Mines in Jermyn-street, and the Royal Institution in Albemarle-street, the use of the theatres of both these buildings having been granted. Two hundred and fifty foreign medical men have up to this time definitely announced their intention to attend. Abstracts of papers are rapidly arriving for translation into the three official languages of the Congress; these will be regarded as strictly private communications until the opening of the Congress, when they will be published in connexion with the programme already in circulation. Unless the abstracts are sent in early the translation and printing of them will become a sheer impracticability. The committee have received fifty guineas from another corporate body, the Faculty of Physicians and Surgeons of Glasgow, thus raising the sum now received from such sources to £235. The London Medical Corporations intend to show all the hospitality in their power; the College of Physicians have most liberally placed their house at the disposal of the Reception Committee for a head-quarters during the meeting, its central position making it especially desirable for such a purpose. The College of Surgeons will entertain the whole Congress at a conversazione in the Hunterian Museum, and the Society of Apothecaries purpose giving a dinner to a number of members in their hall at Blackfriars. The Executive Committee are anxious to make known to the profession that a register now lies at the College of Physicians in the charge of Mr. Gurner, where members can inscribe their names and pay their membership subscriptions. The inscription of names in this book is particularly to be wished, since it will very much diminish the press of members who will need to be enrolled on the opening day of the Congress. At the College of Physicians, also, forms are provided to permit those desirous of offering hospitality to enter their own names and the names of the guests they wish to invite.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, May 5th, a petition was presented from the Royal and Parliamentary burghs of Scotland for the abolition of the Scotch Board of Lunacy.

On Friday, in reply to Colonel Makins, Mr. Dodson stated that the small-pox tents at Fulham were near the Imperial Gas Company's works and the Fulham Waterworks, but to no other buildings whatever. Colonel Makins gave notice of a further question with regard to a proposal to erect a temporary hospital at Wormwood Scrubs. Dr. Farquharson gave notice that he will move the rejection of the Vivisection Abolition Bill.

On Monday, the second reading of the Vivisection Abolition Bill was deferred to July 13th. On the motion of Mr. Whitworth, a return was ordered of the amount of alcoholic stimulants used in Irish workhouses during 1880; and on the motion of Mr. J. Talbot, a return was ordered of the deaths from small-pox in the Metropolitan Asylums District from January 1st to April 30th, 1881. On the motion of Sir R. Cross, a select committee was appointed to inquire into the working of the Artisans and Labourers' Dwellings Acts. In reply to Colonel Makins, Mr. Dodson stated that the Fulham District Board applied to the Metropolitan Board of Works for permission to erect a temporary small-pox hospital at Wormwood Scrubs, and the application was refused, on the ground that the Act of Parliament under which the common was managed did not authorise its use for any such purpose. Replying to Mr. Hollond, Mr. Dodson said that as far as he could learn action under the Artisans' Dwellings Acts had been taken by local authorities only in two or three cases. The Local Government Board had issued a model set of by-laws under Section 90 of the Public Health Act, but of course the actual making of by-laws rested with the local authorities. Mr. Chamberlain, in answer to questions by Mr. O'Donnell and Lord Lymington, stated that the Board of Trade officers were making inquiries into the alleged "horrors on board an emigrant ship," described in the *Pall Mall Gazette* by Miss C. O'Brien. Mr. Fawcett informed Mr. Parker that he was about to make an experiment, which he hoped would be successful, in employing some deaf and dumb persons in sorting papers in the Savings Bank Department of the General Post Office.

Maintenance of Lunatics.

On Tuesday, Mr. Stanley Leighton gave notice that he would, on the 31st inst., call attention to the state of the law relating to the superintendence and maintenance of lunatics, and move, That it is unfair to the ratepayers to oblige them to maintain, out of the poor rates, asylums which are largely occupied by the middle and professional classes; that the practice of granting licences to individuals which authorise them to make a profit by keeping persons in private asylums is liable to abuse; and that it is the duty of the Government to undertake the charge of all lunatics.

Limerick Lunatic Asylum.

On Wednesday, Mr. O'Shaughnessy gave notice that on Monday next he will move for a return of the number of persons now inmates of the Limerick Lunatic Asylum charged to the city of Limerick; and on the same day will ask the Chief Secretary to the Lord Lieutenant of Ireland, if it is not true that the rates of the city of Limerick have lately become charged with the maintenance in the Limerick Lunatic Asylum of several persons, not natives or inhabitants of the city, who, being prisoners in the Limerick District Prison, were transferred thence on account of mental derangement to the Limerick Lunatic Asylum, and several soldiers, enlisted in the city, who, having become mentally deranged in the service, were transferred from Netley to the Limerick Lunatic Asylum.

Small-pox.

On Thursday, Mr. Hopwood asked the President of the Local Government Board whether it be the fact that Dr. Stevens, one of the inspectors appointed by the department at the board of guardians for St. Saviour's, Southwark, recently suggested that in future all children born in the workhouse should be vaccinated before they were allowed to leave, however young they might be, and, in answer to questions, was clearly of opinion that the guardians had the power to enforce this, even without the consent of the mother, upon admission. It was pointed out to him that, in the opinion of some medical men, this would be injurious to the mother, by causing much mental anxiety, and that fatal cases of this kind had been known, but he replied that it would cause the mother still greater anxiety were the child to have small-pox. And whether such a course of proceeding is justifiable by any, and what, law; and, if not, whether he will not at once express disapproval of it. Mr. Dodson said he found Dr. Stevens did suggest that children born in the workhouses should be vaccinated before leaving; and that, subject to the opinion of the medical officer in any particular case, it should be done on the sixth day after birth. Dr. Stevens did not express any opinion of his own as to whether the guardians could enforce this without statutory power, but he did refer to an opinion of the Poor Law Board to the effect that they could. That opinion seemed to have been given as far back as 1848. Mr. Hopwood asked if the right hon. gentleman would answer the last part of the question. Mr. Dodson said his own opinion was that vaccination could not be enforced if the mother objected.

Mr. W. H. Smith asked the President of the Local Government Board if he was aware that the small-pox hospitals of the Metropolitan Asylums Board were full, and that persons suffering from small-pox were now lying in lodging-houses in crowded neighbourhoods, to the great danger of the other inhabitants; and whether he would state what steps he proposed to take to provide the Asylums Board with the necessary powers to deal with the epidemic, and with sufficient authority to carry out the Metropolitan Poor Act, 1867. Mr. Dodson was sorry to say that the small-pox hospitals in the metropolis were full or nearly so. He had no information as to persons suffering from small-pox lying in lodging-houses, although he feared such might be the case. He had hoped that supplementary provision would have been made by the guardians of the district boards, and to some extent that had been done, but he deeply regretted to say that in other cases exertions that were made were paralysed by threatened legal proceedings. He was glad to announce that the Metropolitan Asylums Board were exerting themselves to the utmost to provide accommodation for 300 or 400 convalescents, which would considerably relieve the hospitals; and he might add that the Local Government Board were in communication with the managers respecting immediate further provision.

Correspondence.

LIVER ABSCESS AND DYSENTERY.

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 7th, 1881, in which you refer to the recent discussion at the Pathological Society on liver abscess in connexion with dysentery, it is remarked that I reaffirmed the opinion that the solitary abscess is usually the outcome of primary hepatitis, independently of dysentery, which may or may not be a concomitant, but that "many of those who spoke took the contrary view." It is further stated that you "believe that there is evidence of primary hepatitis even in cases of hepatic abscess arising in our climate under certain conditions where there has been no trace of intestinal ulceration, and where everything pointed to primary inflammation, or where, in some cases, thrombosis with necrosis of the liver was the cause of the abscess. In other cases a single abscess may result from a local infective process from diseased intestines. Such cases, however, may be originally produced by the fusion of several 'multiple' foci of secondary inflammation; but whether this be so or not they do not strictly come under the category of 'tropical abscess,' being linked etiologically with those cases of disseminated suppuration of the liver which are admitted by all to follow upon ulceration of the intestines, as well as upon other sources of pyæmic infection." With your permission I should like to make a few remarks on the subject, in confirmation of the views you uphold. In the first place, I would say that tropical abscess, though generally large and single, is not invariably so; that, though frequently associated with dysentery, it is often altogether independent of that disease, though co-existent in certain cases, and probably due to the same climatic cause as dysentery; yet that there is no direct connexion between them, and that in a large proportion of cases there is no evidence of dysentery having existed during any period of the disease. The fact probably being that this form of liver abscess is generally independent of the bowel ulceration, though due to the same cause. It might be further stated that it would be impossible to predict, if a number of men were exposed to malarial and tropical influences, how many would suffer from dysentery alone, from remittent fever, from liver abscess, and other hepatic disease; or how many from a combination of all these states.

Liver abscess occurring in this country in persons who have not been exposed to tropical influences is probably due to absorption from ulcerated abdominal viscera, or to pyæmia from other causes, especially such as wounds or injuries about the abdominal or pelvic viscera. These are certainly not identical with dysenteric liver abscess, though analogous to one form of that disease. Probably when they occur, there may have been some morbid condition of the liver substance, which predisposes it to suffer. Doubtless many of the liver abscesses met with in this country occur in persons who have been in the tropics, and may fairly be referred to climatic causes or to dysentery; but I imagine cases of apparently similar character occur from time to time in all countries, that are quite independent of such influences; and that the explanation which refers them to bowel ulceration (not dysenteric) is frequently correct; and I can hardly doubt that even the large, generally single, abscess conventionally called "tropical," may also occasionally be seen in our own and other temperate climates. After all, perhaps, there may not be so very much difference of opinion between the views of those who have observed at home and of those who have observed abroad.

The following are the forms of liver abscess with which my experience has made me acquainted:—

1st. Abscess, generally large and single, though occasionally double or even multiple, may occur in any part of the liver; it frequently forms with much constitutional disturbance: pain, swelling, pyrexia, and sweating, though sometimes these symptoms are almost absent, and so insidious is the process that it is only detected when it discharges its contents through the lung, bowel, or stomach; or when by opening into the peritoneum it causes death; or not until after death, when it is discovered during post-mortem examination. This form of abscess has a tendency to point and open in any of the directions above mentioned; but it also frequently approaches the abdominal or thoracic walls and opens, or is opened, with favourable results, either in the epigastric or hypochondriac regions, below or between the ribs, in front or behind. Many cases that have opened spontaneously through the lung, stomach, and bowels, recover perfectly; not so, I fear, when the pericardium or peritoneum are invaded; unless, indeed, in some rare cases where portions of those cavities have been isolated by the inflammatory process, and the effusion thus limited within the bounds so formed. Recovery after paracentesis is sufficiently frequent to render cases in which it is performed, at the right period, very hopeful; though, of course, they are necessarily always cases of great anxiety as well as uncertainty. This, the so-called tropical abscess, from its greater prevalence in tropical or subtropical countries, is due then to climatic causes, such as heat, malaria, over-stimulation of the liver from errors in food and drink, and the greater work thrown on the organ under the circumstances above named. It is generally unaccompanied by, and apparently independent of, dysentery or other form of bowel complaint, though it may be associated with that disease or with malarial fever; but, according to my belief, though due to the same *cause* it is *coexistent with*, rather than *dependent on*, them, and it frequently happens that post-mortem examinations confirm this view, showing the absence of evidence of existing or past dysenteric ulceration. But, assuming that the poison, or the cause of dysentery whatever it be, is of a specific character, there is, I think, some ground for believing that it may act *directly* on the liver, irrespective of transference from the intestines, and so give rise to a true dysenteric hepatic abscess. Such cases, however, I should regard as exceptional.

Tropical liver abscesses, I would remark, sometimes assume a very chronic and quiescent condition, and may remain for months, perhaps years, causing failing health, of which the true nature is almost unsuspected until some fresh disturbance or inflammation excites them into activity, though they are not always difficult of diagnosis. There is good reason for believing also that they sometimes dry up and disappear spontaneously by absorption. I have seen cases in which, I believe, this has occurred. There is, in my opinion, therefore, reason for believing that a large number of cases of so-called tropical liver abscess are independent of dysentery, and these are generally, though not invariably, solitary.

2nd. Abscesses frequently, not however invariably, multiple, of various sizes, from a pea to a hen's egg, or larger, scattered about throughout the parenchyma of the liver, and containing pus, puriform matter, and débris of disintegrated liver tissue, accompanied by, or following and *caused by*, dysentery, are not uncommon. They are, I believe, the result of either direct absorption of septic matters from the ulcerated bowel, through the portal vein, or are due to the more general condition of pyæmic poisoning which is set up by the disease, just as happens in pyæmia from other causes, such as wounds, injuries, and operations, especially when they involve the abdominal or pelvic viscera. I have frequently, in India, seen these pyæmic abscesses scattered about in the liver, lungs, kidneys, and spleen, in varying numbers, from one to many, after death from pyæmia, where there was not a trace of dysenteric ulceration in the bowel. I would remark that though most frequently multiple they are occasionally solitary, and that the mere fact of being single does not invalidate the probability of a pyæmic origin. I would also call attention to the pathology of these so-called abscesses, which are really at first no abscesses at all, but local deaths; necrotic patches of liver tissue caused by embolism or pyæmia. These patches of dead tissue are surrounded by congested tissue, and ere long by suppuration, the purpose of which is to throw off the dead tissue. Such abscesses when cut into are found to consist of dead tissue and sanies, with puriform matter, and after a certain time, pus; just as in the case of a tropical boil, where a quantity of pus forms round a nucleus of dead areolar tissue, killed by thrombosis. When life is prolonged and inflammatory changes have had time to take place, these necrotic centres or foci become the nuclei of abscesses of considerable size. Needless to say that such liver abscesses are in the last degree dangerous, perhaps generally fatal. I think it would be found, if statistics were appealed to, that they do not support the theory that ordinary tropical hepatic abscess is due to dysentery.

Moore, in the "Annals of Military Surgery," says that eight observers out of twelve reported 1532 cases of dysentery, with 295 cases of liver abscess, or 18 per cent. Other four observers gave a ratio of 39 per cent., or 52 cases of abscess out of 131 of dysentery. Macpherson gives a record of 13 per cent. in the General Hospital of Calcutta. Waring gives 663 cases of fatal dysentery, with hepatic abscess in 149, or 23·54 per cent.; Mr. Eyre, 22·18 per cent.—i.e., 118 cases—with 27 cases of abscess; Mr. Moore, 127 cases, with 27 of abscess, or 22·05 per cent. As Moore says, "If the theory of the formation of hepatic abscess be sound, how is it that 77 per cent. of dysentery had no hepatic disease?"

In conclusion, I would remark that the researches of Indian observers such as Morehead, Macpherson, Maclean, Moore, Martin, Parker, and others, seem to show that hepatic disease is a not unfrequent complication of dysentery, that it is also, and not unfrequently, caused by it. The weight of testimony is, as you say in THE LANCET, in favour of the view of a primary hepatitis, independent of dysentery, and that the same may occur under certain conditions, even in our own country, where there have been no traces of intestinal ulceration, and where all pointed to primary inflammation. The subject is one well worthy of further discussion, both in its European and tropical aspects, and I should be glad to think that the distinguished physicians who discussed it so ably and impartially last Tuesday may deem it worthy of further notice next session.

Yours faithfully,

May 8th, 1881.

J. FAYRER.

OÖPHORECTOMY.

To the Editor of THE LANCET.

SIR,—In reference to my paper on Oöphorectomy, which you did me the honour to criticise in last week's LANCET, I am quite aware that more value would attach to it had I written out more elaborate details of the conditions that existed and were considered to call for the operation. The ultimate effects of the operation can, of course, only be judged of after a longer period than at present has elapsed. I hope in the future to give the results in each case so far as they can be ascertained at the time.

You speak of my unsuccessful cases not having been published. I can only say that up to this date I have had twenty-eight completed oöphorectomies (both ovaries removed), one where only one ovary was removed, and one incomplete case, that of E. H——, mentioned in my paper and referred to by you, also published by me somewhat in detail in a pamphlet last year. These are the whole of my cases, and the patient in each instance recovered.

As showing the difficulty of drawing a line between ovariotomy and oöphorectomy, my last but one abdominal section was commenced with the view of an oöphorectomy being performed. The left ovary was removed; the right turned out to be an ovarian cyst, completely adherent to the pelvic brim and about the size of a Tangerine orange. Under which class of operations should this have come? My friends, Dr. Edginton, who assisted me, and Dr. T. Richards, who kindly sent me the case and who was also present, on being appealed to immediately after the operation, said that it was clearly an ovariotomy. Unfortunately this patient died of septic peritonitis; but I think her death will go to the debit side of ovariotomy rather than of oöphorectomy.

I am, Sir, yours truly,
Birmingham, May 3rd, 1881. THOMAS SAVAGE.

THE OLD UNIVERSITIES AND THEIR MEDICAL DEGREES.

To the Editor of THE LANCET.

SIR,—I think the majority of medical students will feel grateful to you for your article in THE LANCET of April 9th, on the difficulties of obtaining degrees in medicine at our English Universities. I think, if the usual career of a medical student be considered, the cause of these difficulties will be found. Taking the average medical students who, after passing the Preliminary Examination of the college or hall, enter one of the London hospital schools and commence their studies for the Primary Examination of the Royal College of Surgeons, we may suppose in eighteen months all the best men to have passed, and it is at this time (and not before) we hear them expressing their regret that it is almost impracticable for them to proceed to a degree in our English Universities. Where does the evil exist? For answer one has but to look at the regulations, and list of students, of the University of Durham, which is the only English University that has recognised and is attempting to remedy it. In these regulations we find—

1. That only one year's residence is required for a degree, the said one year to be spent in a school which is about the best provincial school in England.

2. The Preliminary Examination in Arts of other bodies is recognised *pro tanto*, and the extra subjects required may be passed at any time before one presents himself for the final Professional Examination for the degree.

3. The fees are moderate and carefully arranged, so that a degree can be obtained with very little more expense than the licence of the College of Physicians of London. And who do we find availing themselves of these well-arranged regulations? Chiefly the class of students I name, for on turning over the list of the 177 students for this year studying at Newcastle, I find that out of this number there are thirty-five qualified men, one of whom is a Fellow of the Royal College of Surgeons, and several are Licentiates of the Royal College of Physicians of London and Edinburgh. But why do we find London men putting themselves to the inconvenience of residing in Newcastle when they might obtain a degree at home of far greater worth in the eyes of the medical profession? I do not for one minute believe that it is because they think they will obtain an easier examination at Durham, for its examinations are far from easy, and will well bear comparison with those of Oxford and Cambridge.

In answer to this question I think I may safely assert that if the London University would recognise medical studies pursued previous to passing the matriculation examination (provided always that the candidate was during the time on the Student's Register), and would recognise the Arts Examinations of other bodies *pro tanto*, we should at once see a great improvement in the number of students working heartily for the splendid degree that University gives.

Of the other Universities I cannot say much. Of Oxford I know nothing personally, but of Cambridge I may say this—that the practical hospital teaching is such that the majority of Cambridge students know no more of practical medicine and surgery, after four years' attendance on the practice of Addenbrooke's hospital, than an average London student knows after the first six months of his attendance in the wards of his hospital.

It may seem presumption on my part to attempt to advise the London University in this matter, but when one hears, as I did the other day, one of the best men of the Middlesex Hospital speak of going to Edinburgh for a degree, surely there is something wrong in London which is right in Edinburgh.

I am, Sir, yours obediently,
April 12th, 1881. A CAMBRIDGE UNDERGRADUATE.

STATISTICS OF COLOUR-BLINDNESS AMONG RAILWAY EMPLOYÉS.

To the Editor of THE LANCET.

SIR,—In an editorial notice of the examination of *employés* in India in your number for Oct. 2nd, 1880, p. 550, you mention it as a curiosity that so few Europeans there were found colour-blind. I would respectfully question whether this was not wholly due to the faulty method of examination which has prevailed till within a very short time, and still prevails in England, except with a few gentlemen among you who have taken up Professor Holmgren's method quite recently. From these gentlemen I hear that tests by proper methods show the same percentage in males as elsewhere in the world.

Even expert examiners using the best methods will report very varying percentage. I have been through several classes of fifty each in our schools without finding any colour-blind, and then in the next class there would be enough to bring the per cent. up to the average—viz., four. This last week in a high school in Salem, among seventy-two boys I found five colour-blind, but there were two colour-blind families represented: one of two brothers whom I had known as being defective from their mother having sent me the worsteds they confounded, which were Holmgren's green and a reddish-brown; and two of seven brothers, the others of whom I have not yet tested.

Recent experience has shown in this country that on railroads where the *officials* had tested their *employés* as instructed by railway commissioners, *ophthalmic surgeons* afterwards found 7 per cent. colour-blind and 14 per cent. with defective visual power. I do not think that science can accept any statistics unless we know the precise methods used and how these were carried out, and by whom.

I remain, Sir, respectfully yours,
Boston, U.S.A., April 4th, 1881. B. JOY JEFFRIES, M.D.

"THE LAWS OF THERAPY."

To the Editor of THE LANCET.

SIR,—I do not care to join in the discussion going on in your pages as to whether "orthodox" practitioners should meet homœopathists in consultation. That is a question that does not interest me in the slightest degree, for during a practice of now nearly forty years, I have never had the slightest wish to obtain the opinion of an "orthodox" physician on the subject of the medical treatment of a case. But I confess I am very much interested by a statement made by yourself in a note appended to Dr. Flint's letter in your impression of May 7th. You there say: "Neither ipecacuanha, Dover's powder, nor picrotoxin acts homœopathically or allopathically; the action is in each case strictly in accordance with the known laws of therapy." Pray oblige a searcher after truth, and direct me to where I may find "the known laws of therapy" set forth. That ipecacuanha in large doses will cause vomiting, and in small doses will sometimes cure it, I know not only from Ringer but from frequent experience, and this is undoubtedly an illustration of the homœopathic rule of treatment; but I quite agree with you that the fact itself does not show that the ipecacuanha acts homœopathically. We don't know how a remedy selected according to the homœopathic rule for treatment acts, and though some of us have tried to guess, our success has not been great in this direction. It would therefore afford us much satisfaction if you will kindly show what are "the known laws of therapy" in accordance with which ipecacuanha acts in curing, say, a case of vomiting. We homœopathists only see in our formula *similia similibus curantur* a rule for the employment of medicines in disease that was discovered, we may say, empirically. If "the known laws of therapy" will explain to us how medicines act in the cure of disease, we shall be only too happy; and on this ground, which would be a real scientific ground, we might perhaps find a happier *modus vivendi* with our "orthodox" brethren than we at present possess.

I remain, Sir, your obedient servant,

London, May 9th, 1881. R. E. DUDGEON.

⁂ It is inconceivable that Dr. Dudgeon does not recognise the well-known fact that *all* drugs act differently,—and, as it may seem to the unscientific, on totally opposite lines—in different doses. It is so with every form of vital function, and it is only natural that it should be so with the action of drugs on the organism. Stimulation of a nerve produces first excessive activity, and then an arrest of its special function: and a small dose of a drug produces one effect, while a larger dose produces a different and, almost uniformly, an apparently opposite, effect. The two "effects" are correlated, and mutually dependent, being governed by the same law. It is scientifically absurd to call one stage of the process a manifestation of the operation of "like" and the other of "contradictory." It would be just as reasonable, and no more so, to predicate a "homœopathic" or an "allopathic" property of nervous tissue because it acts on muscular tissue by stimulating it to contraction in one stage, and arrests its action and relaxes in another. No special work expounds this doctrine, because it is the universal law of therapy.—ED. L.

IRELAND.

(*From our own Correspondent.*)

AS mentioned by you last week, Mr. John K. Barton will be a candidate for the Vice-Presidency of the Royal College of Surgeons in Ireland, a probability to which I drew attention three months since. It was rumoured that two candidates would come forward, but it is likely that Mr. Barton—than whom a more eligible candidate could not be selected—will be returned unopposed. Mr. Chaplin, of Kildare, the present vice-president, will necessarily become president next June, and no doubt exists that the great majority of the Council will be re-elected.

An election for examiners in the College of Surgeons took place last week, when all the outgoing members of the Surgical Court, although opposed by four other candidates, were re-elected. The examiners in Midwifery were also re-elected, and the only change occurred among the examiners in General Education, where Mr. Davys was replaced by Mr. Tweedy. At the last general meeting of the Fellows it was resolved that the Council be recommended to take such steps as might be necessary for the holding of the general annual meeting of the College on the Saturday preceding the first Monday in June of each year, in order that the attendance of the Fellows who reside at a distance might be encouraged. With a view to carrying this into effect the Council have recently issued a circular to the Fellows requesting them to state whether they would prefer that the meeting of the Fellows to receive and discuss the annual report of the Council should take place, as heretofore, on the last Monday in May, or the Saturday preceding the first Monday in June. It is probable that the latter arrangement will be selected by the College.

In the proposed scheme of Education and Examination of the Royal College of Surgeons, which most probably will be adopted, as a large majority of the Council are in favour of it, the student who desires to obtain the licence of the College must pass four professional examinations. The candidate will be examined in anatomy at each of the four examinations, a regulation which, combined with the extra expense which will be incurred under the new arrangement, will undoubtedly lessen the number of applicants for the diploma in surgery as compared with those seeking admission under the present system.

The Scheme of Organisation of the Royal University of Ireland as adopted by the Senate has been issued as a Parliamentary paper. The regulations for the medical portion of the curriculum were published in THE LANCET (pp. 504–641), and no alteration of the arrangements there laid down has taken place. Some slight additions may, however, be noticed; for example, besides the necessary hospital attendance, candidates for medical degrees will be required to produce certificates of personal attendance on fever cases; of having compounded medicine for at least three months; of practical instruction in vaccination, and attendance on a course of lectures not less than twenty-five in number, and clinical instruction on mental diseases. The fee for the examination for the M.D. degree has been fixed at £5. Finally, the Senate require of each school seeking recognition a guarantee that in each class a roll shall be kept, which shall be called at the commencement of each lecture, the presence or absence of each student being thereon marked, such rolls to be open to the inspection of any person or persons whom the Senate may appoint for the purpose.

At a meeting of the Governors of Steevens's Hospital, Dublin, held last week, George H. Porter, M.D., Surgeon to the Queen in Ireland, was elected consulting surgeon to the hospital, in the vacancy caused by the decease of Mr. Christopher Fleming.

At a recent meeting of the Managing Committee of the Cork-street Fever Hospital the registrar reported that the hospital had been in a favourable state during the past month, fever having considerably abated, and small-pox entirely disappeared, with the exception of one case—a child, who appeared to have contracted the disease in London,—and which terminated fatally after four days in hospital. Plans are being taken for the formation of a new convalescent home, for which the Committee hope to obtain the necessary funds, and be enabled to proceed with its construction during the summer.

The Cunningham Gold Medal of the Royal Irish Academy has been conferred on Mr. Howard Grubb, in consideration of the eminent services rendered to science by improvements in the construction of telescopes.

The death is reported of Surgeon-Major Walter Blake, A.M.D., at Queenstown, on the 7th inst.

PARIS.

(*From our own Correspondent.*)

A NEW bi-aural stethoscope has been presented to the Academy of Medicine by Dr. Constantine Paul. The chest piece is surrounded by a circular box which is connected by a tube with an india-rubber ball. Upon aspirating with the ball the box when placed upon the skin adheres like a cupping glass, and the rarefaction of the air in the circular sucker is said to increase the intensity of the sounds. The instrument is completed by a Y-shaped metallic branch which emerges from the apex of the chest-piece, and which terminates in two flexible tubes for insertion in the ears. Another novel arrangement which can be made in the apparatus is the addition to each terminal tube of a secondary dichotomous metallic branch, to which are again attached a couple of terminal tubes. The further development of this system of dichotomous branching enables any number of auscultators to listen simultaneously to the same sound.

Antiseptic surgery is gradually gaining favour amongst French operators; but an occasional manifestation against it is made by some of the older members of the profession. At the Société de Chirurgie, M. Boinet has recently returned to the same objections that were advanced some two years since by M. Lucas-Championnière. In the first place, he claims that the credit of the application of carbolic acid in surgery is not due to Lister, but to the French school, and having demonstrated this, presumably to his own satisfaction, he goes on to affirm that antiseptic surgery is both useless and dangerous. This is attempted to be proved by two facts. On one occasion M. Boinet used antiseptic dressings in a case of ovariotomy and the patient died, "probably on account of the irritation of the peritoneum by the carbolic acid."

In a recent work on the effects of electricity in gynecological practice, Dr. Georges Apostoli comes to the following conclusions. Faradisation of the uterus is always inoffensive, it is constantly calming, and sedative. After parturition it shortens convalescence, accelerating the involution of the uterus, which, even with deep palpation, cannot be felt above the pubis after the sixth or eighth day. Faradisation is the best preventive treatment of uterine flexions and versions usually occurring after delivery. It seems to diminish the lochial discharge; its action as compared with ergot is quicker and more energetic.

Obituary.

R. W. FALCONER, M.D., D.C.L. DURH.

RANDLE WILBRAHAM FALCONER was the son and grandson of physicians of considerable eminence and fame in the ancient city of Bath, and had the advantage of inheriting and the honour of perpetuating a good name. Receiving his professional education at Edinburgh, he took his M.D. degree at that University in 1839, and at first settled in practice at Tenby, but after eight years moved to his old home, and was there busily engaged up till the very day of his death. He early became connected with the General and Mineral Water Hospital at Bath, and published some works on the value of the Bath waters in rheumatism and allied affections. Although busily engaged in a large and successful practice, Dr. Falconer was greatly interested in, and devoted a good deal of attention to, archæology and biological science, and also took a prominent part in local public affairs. He filled the office of mayor in the year 1857–8, and at the close of his term of office was unanimously re-elected. He was a prominent member of the British Medical Association, and held successively the offices of treasurer, president of the council, and president.

His death took place quite suddenly, while he was actively engaged in the practice of his profession. For some time past symptoms of a weak heart had shown themselves, and not long ago a serious syncopal attack gave warning of the approaching end. On the 5th inst. Dr. Falconer felt wearied before he had quite finished his rounds, and had to rest awhile at his club before proceeding home. Quite early next morning he was seized with dyspnœa, and in spite of all the skilful efforts of his medical friends, the prostration steadily increased, and he died the same evening. He had attained the age of sixty-five.

In addition to his university degree and the membership and fellowship of several societies, he was F.R.C.P. Lond. and D.C.L. Durh. His sudden removal from the midst of his active duties has caused a general feeling of regret, not alone among his patients, who have lost a wise adviser and friend, but throughout all classes in the city, for in many ways he proved himself a good citizen, and his memory will long be cherished with affectionate respect.

WM. SIMPSON, M.R.C.S., L.S.A.

WM. SIMPSON of Bradmore House, Hammersmith, has joined the great majority. Although his name may be known to but few of the present generation, his career has not been an undistinguished one. He entered at the united hospitals of Guy's and St. Thomas's in 1820, became a Licentiate of the Society of Apothecaries in 1824, and Member of the College of Surgeons in 1825. He commenced practice in Hammersmith, where he met with deserved success, his kindness to the poor, and disregard of his own safety in succouring the sick during the cholera epidemic, rendered his name a household word with those among whom he laboured. In spite of an increasing practice he found time for literary work. He contributed many cases to THE LANCET, which was then a young journal. He was editor and proprietor of *The Scalpel*, but the success of that paper did not warrant its continuance beyond a year or two. He also brought out "An Aid to Students for the Examination of the Apothecaries' Hall."

In 1850 he retired from practice and devoted himself to politics. He made his first and only appearance on the hustings at High Wycombe in 1852, when he contested the seat in the Liberal interest, but was beaten by Sir Geo. Hy. Dashwood. Though beaten, however, he was not disgraced, and as a mark of their appreciation of the zeal and purity with which he contested the election, the electors presented him with a magnificent silver cup.

In 1866 Mr. Simpson sustained an irreparable loss in the death of his wife, who had been his faithful companion for forty-five years. A severe illness at this time brought on paralysis agitans, and though the mind was as clear and active as ever the body was to all intents and purposes dead; but his cheerfulness never forsook him. Nursed by his niece, Miss Roy, who also read the daily papers to him, and the new books as they came out, for fourteen years he remained in this state of helplessness, until relieved by death on April 24th, 1881.

SAMUEL JOHN TRUMAN, M.R.C.S.

MR. TRUMAN, whose death took place at New Basford, Nottingham, on March 2nd, was the fourth son of Beckett Truman, Esq., who practised in Nottingham upwards of fifty years. He studied at Guy's Hospital, became house-surgeon in the Manchester Infirmary in 1868, and afterwards of the Lincoln General Dispensary. He then purchased a practice at Rippingale, in Lincolnshire, where he married. Five years since, owing to the delicate health of his family, he took up a portion of his father's practice in New Basford, where he soon became popular. His was one of those anxious and painstaking temperaments which, combined with a pleasing manner, soon establishes a cordial sympathy with patients and friends, and obtains a wide respect, but at the expense of a rapid wearing out of the constitution. Frequently, after his professional rounds, Mr. Truman reached his home exhausted and faint, and on the 1st of March he was brought back in his carriage in a state of syncope, from which, however, he rallied. He was attended by Messrs. Burnie and Macdonald, but expired suddenly early on the following morning. At the inquest the medical evidence was to the effect that death was caused by "pericarditis and syncope."

His sudden death, at the age of thirty-five, was regarded as a public calamity in the neighbourhood, and over a thousand persons sought and obtained a "last look" at their departed friend and doctor. Amongst these were several who were former patients in the Manchester Infirmary.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on Monday, Tuesday, and Wednesday last:—

H. H. Brown, Aberdeen; Thomas Birt, John F. Vince, Edwin W. D. Kite, and H. Simms, Birmingham; John F. L. Whittingdale and Walter Dawson, Cambridge; Matthew Johnston, John T. Walker, Charles N. Bensley, Morris J. Williams, Francis J. Stevens, Alfred A. Lankester, William C. Dalley, Thomas Jones, Alfred D. Edginton, and James H. Menzies, St. Bartholomew's Hospital; Robert K. Peacock, Edinburgh; Edward H. Armitage, James C. Bates, Arthur C. Deare, Hugh Lamb, Francis Heatherly, George E. Stewart, and Alfred E. Taylor, Guy's Hospital; Edward Stewart, Middlesex Hospital; William Turnbull, James M. Robson, and Frederick M. Blackwood, Newcastle-on-Tyne; Robert C. Bruce, Edinburgh and Charing-cross Hospital; Richard A. Jackson, St. George's Hospital; Edwin Roberts, Leeds; John Williams, Liverpool; Cadwallader E. Evans and F. W. Weir, Bristol; Thomas G. Parrott and Edward S. Hasell, King's College; F. de C. Skeete, University College; L. P. Mumby, Westminster Hospital.

[In the list published last Saturday of gentlemen who passed the Primary Examination at the College, for "William Fowler" read "Walter Fowler."]

UNIVERSITY OF DURHAM.—At the First Examination for the degree of Bachelor in Medicine, concluded on

Friday, April 29th, the following candidates satisfied the Examiners:—

Austen, Henry Hinds, M.R.C.S.
Beatley, William Crump.
Brown, Arthur Tresco Franklyn.
Brown, Richard.
Cock, Frederick W.
Doudney, George Herbert.
Hardie, Robert.
Hepworth, Arthur.
Howitt, George Grahamsley.
Hudson, Theodore J., L.R.C.P., M.R.C.S.
Hutchinson, Joseph Armstrong.
Lingard, Alfred, M.R.C.S., L.S.A.
Morgan, Llewellyn Arthur.
Norry, William Augustus.
Paley, Wm. Edmund, F.R.C.S.E.
Price, William Elliott.
Prowde, E. Longstaff, M.A.Cantab.
Ridley, George Walter.
Salvage, John Valentine.
Shuter, Charles Yalden.
Spicer, Frederick.
Tomson, Walter Bolton.
Turnbull, William.
Triay, Abelardo J., B.A., L.M. & S.
Vise, Christopher, M.R.C.S.
Walker, Basil Woodd, L.R.C.P., M.R.C.S.
Wigan, Charles Arthur.

Thirty-eight candidates entered for the examination, two withdrew, and nine were referred to their studies for a period of six months.

Faculty of Physicians and Surgeons of Glasgow. — At the April sittings of the Examiners the following gentlemen passed the Primary Examination:—

John Cable, J. Engles, D. P. Gage, H. G. Hughes, Robert Jope, H. C. Long, Wm. Middleton, W. Morris, Robert Rudland, R. W. Sclater, H. Sinclair, Oliver Sunderland, and Hugh Thomas, Glasgow; J. H. Blayney, Manchester; T. G. Hull, Leeds; J. F. Hobbes, Birmingham.

The following passed the Second Professional Examination and were admitted Licentiates:—

Bridgman, H. A., Ramsay.
Dell, J. F., Herts.
Donkin, Charles, Weybridge.
Hutchison, T., Barnard Castle.
Heron, A. W., Jamaica.
Ramsay, E. C. A., Fleetwood.

Royal College of Physicians of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—At the April sittings of the Examiners the following gentlemen passed the Primary Examination:—

P. F. Shaw, Glasgow; G. D. Trevor-Roper, Manchester.

The following passed the Final Examination and were admitted Licentiates of both bodies:—

Guest, A. H., Glasgow.
Horn, Robt. J., Atterborough.
Murdoch, Alex. M., Glasgow.
Thomson, A. T., Metheringham.

Apothecaries' Hall.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on May 5th:—

Damania, Bhicajee Jivajee, Bombay.
Wilde, Frederick, Euston-road.

It is announced that the Prince and Princess of Wales will be the guests of the Treasurer of St. Bartholomew's at a conversazione to be given at the hospital on the 27th inst.

The Duchess of Edinburgh will open the bazaar in aid of the building fund for the extension of the National Hospital for the Paralysed and Epileptic, Queen-square, to be held at the Duke of Wellington's Riding-school, Knightsbridge, upon the 17th, 18th, and 19th of May.

At the thirty-third anniversary festival of the City of London Hospital for Diseases of the Chest, held at the Cannon-street Hotel on the 8th inst., donations to the amount of £2050 were announced. It was stated that £9000 were required to carry on the work of the institution on its present scale, and the annual subscriptions represented only £2400 of this sum.

St. Mary's Hospital.—On Wednesday the annual dinner in aid of the funds of this hospital was held at Willis's Rooms, Earl Stanhope in the chair. The munificent bequest of £25,000 by the late Mr. Stanford, for the purpose of enlarging and improving the building, was mentioned; and in reference to the maintenance of the new wing, the chairman suggested that paying wards, similar to those in use at St. Thomas's, should be established, and that the payment of a certain sum should be required of out-patients. Subscriptions to the amount of £650 were announced.

The will and codicil of Dr. William Hardwicke, coroner for Central Middlesex, late of Holder's-hill-house, Hendon, who died on the 15th ult. at Fulham-place, Paddington, were proved on the 19th ult. by Mr. Arden Hardwicke, the son, and Mr. J. W. Marchant, the executors, the personal estate being sworn under £4000. The testator bequeathes to his wife, Mrs. Sophia Hardwicke, a pecuniary legacy of £250; the residue of his real and personal property he leaves upon trust for her for life, and then for all his children in equal shares.—*City Press.*

Cantor Lectures.—The fifth and concluding course of Cantor Lectures for the present session, at the Society of Arts, will be delivered by Mr. R. Brudenell Carter, on the subject of "Colour Blindness, and its Influence on Various Industries." The first of the course of three lectures will be delivered on the 16th inst. This lecture will deal generally with the subject. The second will treat of methods of testing for colour blindness, the prevalence of the affection, mistakes of the colour blind, and methods of endeavouring to counteract the defect. The industries chiefly affected by colour blindness will be dealt with in the third lecture.

The Nightingale Fund.—The Council of the above Fund held their annual meeting on Friday last, at the Nightingale Home, St. Thomas's Hospital, when the report on the Nurse-training School for the year 1880 was read, and addresses were delivered to the probationer-nurses. Sir Henry Verney, Bart., M.P., the chairman of the Council, who was accompanied by Lady Verney, presided, and was supported by Mr. W. Bowman, F.R.S., Sir William M. Muir, K.C.B., Mr. W. Rathbone, M.P., members of the Council; Mr. Henry Bonham Carter, the secretary; Mrs. Wardroper, the lady-superintendent of the School; and Mr. Croft, F.R.C.S., the medical instructor. There were present also the Treasurer of St. Thomas's Hospital, several of the medical staff, and other visitors. The report mentioned that during the year 1880 twenty-five probationer-nurses had completed their training, so as to entitle them to be placed on the register as certified nurses, and had been appointed to situations. Thirty-nine admissions to the school had taken place, and, some having resigned or been discharged, there were thirty-two in residence at the end of the year.

Presentations.—Mr. W. T. Dinnen, of Holyhead, has received a gratifying token of the esteem of the inhabitants of Holywell, where he had resided as house-surgeon to the Flintshire Dispensary. The testimonial was in the form of a diamond breast pin and an illuminated address expressive of the best wishes of the donors for Mr. Dinnen's welfare in his new sphere of practice.—The parishioners of Newhills, Dyce, and Newmacher, Aberdeen, have presented Dr. John Carlyle with a gold watch and an oil portrait of himself on the occasion of his leaving the neighbourhood.—The senior house-surgeon of the Torbay Hospital, Mr. G. W. Hamilton Cumming, having resigned his appointment in order to practise at Wick, Bath, his friends took advantage of the occasion to present him with a testimonial to mark their sense of his conduct during the short time he had been amongst them. This was subscribed for by the weekly board on behalf of the hospital, and by the members of the board, the medical staff and the officials, nurses, and servants of the establishment. The presentation consisted of a silver and oak tea tray, salad bowl, and other valuable articles.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

Allen, A. H., F.C.S., has been reappointed Public Analyst for the Borough of Sheffield.

Bernstein, Dr. M. J., has been elected Senior House-Surgeon to the Borough Hospital, Birkenhead, vice Dr. Baker, resigned.

Bird, T., M.A., M.R.C.S.E., has been appointed Instructor in the Use of Anæsthetics at Guy's Hospital.

Brew, H. B., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer for the Bray (co. Dublin) Dispensary District.

Briggs, H., M.B., M.R.C.S.E., has been appointed Resident Medical Officer to the Liverpool Royal Infirmary, vice R. H. Jones, resigned.

Brown, E., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Braughing District of the Bishop Stortford Union.

Clarke, Mr. F. H., has been appointed House-Physician to the Western Infirmary, Glasgow.

Davidson, Mr. A., has been appointed House-Physician to the Western Infirmary, Glasgow.

Dickson, Mr. G., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

Downie, Mr. J. W., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

Finch, H., M.D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Colchester Urban Sanitary District, vice Waylen, resigned.

Glaister, J., M.B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Lecturer on Medical Jurisprudence in the Royal Infirmary School of Medicine, Glasgow.

Griffith, J. de B., M.B., M.Ch., has been appointed Resident Medical Officer at the Yarra Bend Lunatic Asylum, Melbourne.

Hopkins, F. F., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the First District of the Aston Union.

Hunt, Mr. J. M., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

Ker, Miss, L.M., has been elected Senior House-Surgeon to the Hospital for Sick Children, Birmingham.

Kinder, R., F.F.P.S.G., has been reappointed Medical Officer and Public Vaccinator for the Haddenham District of the Ely Union.

Littler, J. W., M.R.C.S.E., L.S.A.L., has been appointed one of the Surgeons to the Manchester and Salford Provident Dispensary Association (Medlock-street Branch).

McDonnell, M. A., M.D., M.Ch., has been appointed Medical Officer for the Workhouse, Toxteth-park, Liverpool, vice Lyster, deceased.

Malley, A. C., M.B., B.Ch., has been appointed Medical Officer for the Third District of the Church Stretton Union.

Mason, J. W., M.B., C.M., &c., has been elected Medical Officer of Health for the Borough and Port of Kingston-upon-Hull, vice J. Fearne Holden, deceased.

Moore, H. O., M.B., has been appointed Public Vaccinator for Dandenong, Australia.

Ormsby, G. H., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Officer to the Odd Fellows' Dispensary, Hull.

Pettinger, G. W., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Stretford Urban Sanitary District.

Porter, G. H., M.D., M.Ch., F.R.C.S.I., has been appointed Consulting Surgeon to Steevens's Hospital, Dublin, vice Fleming, deceased.

Priest, J. D., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon and Secretary to the Hertford General Infirmary, vice Vlieland, resigned.

Prichard, Mr. R., has been appointed House-Physician to the Western Infirmary, Glasgow.

Smith, J. M., M.B., C.M., has been appointed House-Physician to the Western Infirmary, Glasgow.

Waite, W. H., L.D.S. R.C.S.I., has been appointed one of the Honorary Dental Surgeons of the Dental Hospital, Liverpool, vice Philips, resigned.

White, A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Crigglestone and West Bretton Districts of the Wakefield Union.

Young, J. M., M.A., has been appointed House-Surgeon to the Western Infirmary, Glasgow.

Births, Marriages, and Deaths.

BIRTHS.

Bennett.—On the 7th inst., at Upper Berkeley-street, Portman-square, the wife of H. Selfe Bennett, M.B. (prematurely), of a son, stillborn.

Davies.—On the 4th inst., at Cwm Dows House, Newbridge, near Newport, Mon., the wife of W. H. Davies, Surgeon, of a son.

Firth.—On the 3rd inst., at St. Giles-street, Norwich, the wife of Charles Firth, F.R.C.S., of a daughter.

Flower.—On the 10th inst., at Lincoln's-inn-fields, the wife of William Henry Flower, LL.D., F.R.S., of a daughter (Augusta Frances).

Fraser.—On the 11th inst., at 7, Lower Church-road, Weston-super-Mare, Somerset, the wife of Græme B. Fraser, M.R.C.S.E., L.S.A.L., of a son.

Ridpath.—On the 2nd inst., at Great Driffield, Yorks, the wife of David Ridpath, M.D., of a son.

Swain.—On the 8th inst., at the Three Counties Asylum, the wife of Edward Swain, Medical Superintendent, of a daughter.

Turnbull.—On the 30th ult., at Kelso, N.B., the wife of G. H. Turnbull, M.D., of a son.

Walker.—On the 29th ult., at The Elms, Parkhurst, Isle of Wight, the wife of George E. Walker, L.R.C.P., of a daughter.

Wright.—On the 2nd inst., at Alexandra-road, Southport, the wife of Strethill H. Wright, M.D., of a son.

MARRIAGES.

Blake—Mounsey.—On the 28th ult., at Goosnargh Church, Lancashire, Henry Blake, M.B., of Great Yarmouth, eldest son of Ethelbert H. Blake, M.D., Deputy Inspector-General A.M.D., to Lucy Agnes, eldest surviving daughter of Lieut.-Col. Mounsey, of Inglewhite Lodge, Preston, Lancashire.

Perkins—Harper.—On the 4th inst., at St. Stephen's, Lewisham, Whitefield Perkins, M.R.C.S.E. &c., of Glastonbury, Somersetshire, second son of J. R. Perkins, Esq., of Birdbush, Salisbury, to Constance Evelyn, youngest daughter of E. Norton Harper, Esq., of Northbrook House, Lee, Kent.

DEATHS.

Barrett.—On the 7th inst., at Pierrepoint street, Bath, J. Barrett, F.R.C.S.E., aged 69.

Bayes.—On the 8th inst., at New Walsingham, Norfolk, Frederick Thomas Bayes, M.R.C.S.E., elder son of F. H. Bayes, M.R.C.S.E., aged 22.

Falconer.—On the 6th inst., at his residence, Bennett-street, Bath, Randle Wilbraham Falconer, M.D., F.R.C.S., Hon. D.C.L., of Durham, youngest son of the late Rev. Thomas Falconer, M.D., of Leighton, Cheshire.

More.—On the 11th inst., at Rothwell, Northamptonshire, the youngest daughter of James More, M.D., aged 4 years.

Neville.—On the 8th inst., at Chorley, Lancashire, Amy, the beloved wife of J. J. Neville, L.R.C.P.Ed., L.R.C.S.Ed., in her 29th year.

Smith.—On the 3rd inst., at Rowlands, St. Mary Cray, Thomas Heckstall Smith, F.R.C.S., in his 75th year.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, May 16.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ A.M. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

St. Mark's Hospital.—Operations, 2 P.M.; on Tuesday, 9 A.M.

Society for the Encouragement of Arts, Manufactures, and Sciences.—Cantor Lectures: Mr. R. Brudenell Carter, "On Colour Blindness and its Influence upon various Industries."

Tuesday, May 17.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 3 P.M.

Royal Institution.—3 P.M. Professor Dewar, "On Non-Metallic Elements."

Pathological Society of London.—(Last Meeting of the Session.)—8½ P.M. The following specimens will be shown:—Case of Intestinal Obstruction; Tumour of Brain, with Polyuria; Heart with Calcareous Plates; Aneurism of Pulmonary Artery; Aneurism of Middle Cerebral; Aneurism of Posterior Communicating; Heart with Aneurism; Case of Pylephlebitis; Ulcer of Stomach in Infant; Partial Dislocation of Astragalus; Fracture of Astragalus; Dissection of Genu Valgum; Syphilitic Disease of Cerebral Vessels; Case of Pseudarthrosis; Lymph Scrotum showing Filariæ; Keloid Tumours of Ears; Specimens of Elephantiasis, &c.; Malformation of the Heart.

Wednesday, May 18.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Operations, 1½ P.M., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ P.M., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ P.M.

King's College Hospital.—Operations, 2 P.M., and on Saturday at 1 P.M.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 P.M.

University College Hospital.—Operations, 2 P.M., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children.—Operations, 2½ P.M.

Association of Surgeons practising Dental Surgery.—7.45 P.M. Council Meeting.—8.30 P.M. Ordinary Meeting.

Sanitary Institute of Great Britain.—8 P.M. Dr. Richardson, "On Suggestions for the Management of Cases of Small-pox and of other Infectious Diseases in the Metropolis and large Towns."

Thursday, May 19.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—1½ P.M. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 P.M.

Central London Ophthalmic Hospital.—Operations, 2 P.M., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2½ P.M.

Royal Institution.—3 P.M. Professor Tyndall, "On Magnetism."

Harveian Society.—8½ P.M. Mr. J. Ernest Lane, "On Two Cases of Popliteal Aneurism."—Dr. G. C. Henderson, "On Cold Bathing in Acute Fevers."

Friday, May 20.

St. George's Hospital.—Ophthalmic Operations, 1½ P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 2 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

Royal Institution.—8 P.M. Mr. W. H. Pollock, "On Shakspeare Criticism."

Saturday, May 21.

Royal Free Hospital.—Operations, 2 P.M.

Royal Institution.—3 P.M. Professor C. E. Turner, "On Russian Literature: Pouschkin."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions submitted to the 143 candidates at the Primary or Anatomical and Physiological Examination for the diploma of Membership of the College, on the 6th instant, when they were required to answer four, and not more than that number, of the six questions, from 1 to 3 o'clock, in Anatomy :—

1. Describe the greater wing of the sphenoid bone.
2. Enumerate the joints in which interarticular fibro-cartilages are found. Describe the shape and attachments of each of these fibro-cartilages.
3. Describe the serratus magnus muscle, its attachments and relations.
4. Describe the course and relations of the abdominal aorta. Enumerate its branches in the order in which they are given off.
5. Give the dissection necessary to expose the external and internal plantar nerves.
6. Describe the general conformation of the thyroid body, and give its relations.

The following were the questions in Physiology, from 4 to 6 o'clock :—

1. What is meant by the impulse of the heart? how is it produced? State the method by which it can be graphically demonstrated.
2. What are the immediate and remote results on respiration of section of both pneumogastric nerves in the neck? How may these results be explained?
3. Describe the structure of dentine, and the contents of the pulp-cavity of a tooth.
4. What is meant by a ferment? What ferments exist in the human body? State the general and special conditions requisite for their action.

. Describe the phenomena of accommodation. What is meant by the terms emmetropia, hypermetropia, myopia, and presbyopia?

6. How is the movement of the blood maintained in the veins? How does the venous current differ from the arterial?

Therapeutist (Dublin).—Yes; resorcine has been employed in cholera infantum, we believe by physicians in Breslau, who report favourably of the action of the drug in the disease.

SPONTANEOUS EVOLUTION.

To the Editor of THE LANCET.

SIR,—Having recently had an interesting case of the above type, I take the liberty of sending the particulars for publication, for though I have been in practice for nearly fifty years, and had a large amount of midwifery, I have not met with one case that terminated as this did. I was called to the wife of a collier at Brotherton, near this village, on April 19th, at 3 P.M. A midwife was first sent for, and she, perceiving the nature of the case, sent for me; and on my arrival I found the right arm and shoulder down very low. The membranes were ruptured at 11 A.M. The poor woman had strong pains, so I gave sixty drops of tincture of opium at once, and after waiting a short time introduced my hand, but found decided hour-glass contraction, which prevented my reaching the fundus uteri to grasp a foot. I then decided to give chloroform, and though I administered the drug freely, I did not get my patient fully under its influence, for whilst I was applying it, she said, "It is coming." I had not attempted turning for twenty minutes, and now, on examination, I found the breech down, and the arm drawn up, so the delivery was soon effected. The child was dead and premature (eight months), the arm and shoulder very black and swollen. I am glad to say the patient did well. I think this is a decided case of "spontaneous evolution," as described by Dr. Denman.

I am, Sir, yours respectfully,
Ferry-bridge, Yorkshire, May 2nd, 1881. WILLIAM R. LOMAS

MEDICINE AMONGST THE CELESTIALS.

MR. MACGREGOR, who has been for sixteen years working as a medical missionary at Amoy, speaking recently at a meeting of students in Edinburgh, said: "The dense and crowded population, and the filthy condition of the people of China, constitute a fruitful source of skin disease, which is very common, so much so, that the Chinese themselves have a proverb—'out of ten men, *eleven* of them have the itch.' Various forms of eye disease are very prevalent, and to cure these the native doctors are quite helpless. Some complaints are due to climatic causes, as, for instance, dysentery and malarious fever. All kinds of tumours are common, and present an excellent opportunity for showing the superiority of European skill, as surgery is quite unknown to the native doctor, who invariably prescribes so much medicine to be swallowed, whether the trouble is an aching head or a broken limb. The practice of the native doctors sometimes tries the patience of the medical missionary very much. The usual way for a Chinaman to enter the profession is to procure a pair of spectacles with large bone rims, some grasses and herbs, an assortment of spiders and a few venomous snakes in bottles, which are placed in the shop window; then the medicine he gives *must* be nasty, and there should be plenty of it, as the Chinese go in for quantity, and reckon how they should be getting on by the amount they have taken. If not making satisfactory progress, he applies to a new doctor, but still continues to take the medicine prescribed by the one he first consulted, so that unless he is under your entire control, he may be taking your medicine, but in all likelihood he is, at the same time, dosing himself with the nostrums of half-a-dozen ignorant charlatans."

VACCINE LYMPH.

To the Editor of THE LANCET.

SIR,—After slowly drying the ivory points, properly charged with the vaccine lymph, I place them in a two-drachm bottle, in the bottom of which a pledget of cotton-wool has been previously placed. Another morsel of cotton-wool is put into the bottle before closing it with an accurately fitting cork. My failures with points thus preserved in China as well as in this country) have been very rare indeed, and I now never use tubes for preserving vaccine virus.

I am, Sir, yours truly,
Shepton Mallet, May 10th, 1881. F. PORTER SMITH.

To the Editor of THE LANCET.

SIR,—I should be glad to know, through the medium of your columns, whether other vaccinators have been unsuccessful in their vaccinations, as I have been, when using the vaccine lymph supplied by the National Vaccine Establishment.—I am, Sir, yours, &c.,
April 27th, 1881. A PUBLIC VACCINATOR.

THE EFFICACY OF SOLID OPIUM IN THE TREATMENT OF ENTERITIS.

To the Editor of THE LANCET.

SIR,—During this severe winter many cases of acute and chronic enteritis have come under my notice, which were treated in the usual way with fomentations and terebinthine counter-irritants. In the management of all these, however, my sheet anchor has been solid opium, the effect of which has ever been most satisfactory.

My object in writing this is to express how much I value the solid form of the opiate over all others in abdominal mischief, and this plan of treatment some time ago I was led to adopt in consequence of its success in a case of serious traumatic abdominal mischief—inflammation both enteric and peritoneal.

The case was this. Mrs. N——, whom I had attended for over twenty years with tertiary syphilis, ultimately got stricture of the rectum, evidently of a syphilitic character; and, besides using the ordinary medicinal treatment for this disease, she was ordered to have applied a rectal bougie daily, commencing at No. 2 and reaching to No. 6. This was done by an efficient nurse for several months, with the best effects, but the nurse being called away on private business, the office was delegated to one who did not understand, properly, the use of a bougie; and one evening in passing it, instead of going through the stricture, she pushed it through the bowel. The consequence was collapse. When I saw the patient an hour afterwards she was in great pain, pulseless, with a cold clammy skin, and unable to speak. Examining the bowel, I could feel the opening, and made certain of the amount of mischief done. Stimulants were given freely, and as soon as the patient rallied one grain of solid opium every hour, with fomentations and turpentine stupes. This treatment was continued, with certain modifications, for a fortnight, with the pleasant result of her complete recovery. Altogether during the fourteen days she took eighty grains of solid opium, and although this happened four years ago, she is now quite well.

My remarks point to this one fact—that the use of solid opium in such cases is more efficacious in the treatment of these diseases than opium n a liquid form either by mouth or hypodermically, and if administered by the mouth more serviceable than when used as a suppository.

There is no novelty in the use of solid opium in such cases, as it has long been a recognised fact in the profession as a "truism" in the treatment of all abdominal diseases.

I am, Sir, yours truly,
April 19th, 1881. JAMES WILLIAMSON, M.D.

CONCURRENT VARIOLA AND VACCINIA.

To the Editor of THE LANCET.

SIR,—The following case seems to me curious, not to say rather startling. O. H——, a strong, healthy, young man of twenty, working in a small-pox infected district, was vaccinated on April 26th. All the signs of successful vaccination were developed. On May 5th the eruption of small-pox appeared, and he now lies under my care with a severe confluent attack.

Presumably the incubation of small-pox began prior to his vaccination, but is it not singular that the incubation of the one and the course of the other should have been concurrent, and equally strange that the most severe form of the disease should have manifested itself? Or is there anything in the theory of worn-out lymph being capable of producing outward signs alone?—I am, Sir, your obedient servant,

May 10th, 1881. IN PERPLEXITY.

SANITATION IN CANNES.

To the Editor of THE LANCET.

SIR,—I have read in the *Italian Times* an extract from your paper giving an account of the intended improvements in the drainage of Cannes. Will you allow me to draw attention to the fact that so long as the authorities permit the sewers to empty themselves into the tideless sea, the promenade and houses near it will get more and more unbearable. I am, Sir, yours truly,

Hôtel des Iles Borromées, Stresa, WALTER HORNBLOWER.
April 28th, 1881.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your report of my paper on Acute Prostatitis in the proceedings of the London Medical Society, published in THE LANCET of this date, the term "prostatic tissues" twice appears instead of "prostatic *sinus*." Perhaps you will allow me to make this correction, otherwise my description of a somewhat rare affection simulating prostatitis is almost unintelligible.—I am, Sir, your obedient servant,

Liverpool, May 7th, 1881. REGINALD HARRISON.

Enquirer.—The report should be written on the same lines as the Instructions of the Local Government Board require for the annual report. If our correspondent has not the Instructions, he should apply to the secretary of the Local Government Board for a copy.

P. R. has omitted to enclose his card.

"A PRACTICAL PHASE OF THE LUNACY QUESTION."

To the Editor of THE LANCET.

SIR,—I read with much pleasure your admirable article on the general treatment of the inmates of our public asylums (see THE LANCET, May 7th, page 749), and am glad to offer my humble testimony to its truthfulness and accuracy. It may be well to go even a step further, and ask why this state of things should exist. The fault lies, as you clearly point out, in the system; yet it is the system on which the managers and committees pride themselves which is at the root of the evil. It may also be remarked, as a rule we do not find that first-rate men in the profession are attracted to this particular department; perhaps it would be difficult, without being invidious, to name any public asylum in which men of leading ability and high professional talent are found. With this drawback there undeniably exists the recognised principle of making things pleasant for all parties: the committee of management, superintendents, general officials, and patients included. To read the annual reports anyone must be struck by the conviction that the pervading tone belongs to the members of a mutual admiration society, and this is kept up by the entire programme on which these establishments are conducted. The lay element of "moral" treatment is everywhere; the medical or scientific nowhere. As the chairman of one of these institutions once remarked to me, we do not want medical skill for the treatment of disease; the general routine of management is most important. Routine is the alpha and omega of modern asylum practice. Reports, daily and nightly; registers, notebooks, forms without end; methodical arrangements; wheels within wheels; inspection and introspection; checks and counterchecks! You observe that "accidents" can scarcely be said to be numerous; it is still more remarkable how very few are heard of. Of course this happy result may be due to the skilful supervision. *Risum teneatis!* Method and discipline are important factors, and cannot be despised, but they do not altogether constitute "psychological medicine."

Something might be done by relieving the superintendent, not, as at present, by giving him subordinates who, if anything, add to his labour, but by dividing the charge into sections of two or three hundred patients, each under a separate medical officer who is responsible only to the committee of management, and three hundred is a sufficient number of patients for the conscientious attention of one man. It may be naturally objected that this plan necessitates smaller salaries; no doubt it would, but it should be also remembered the work is not for the man, but the man for the work, and large salaries do not imply higher results. In these the present system is lamentably deficient; it has been tried and found wanting. A new system is required.

I am, Sir, your obedient servant,

May 11th, 1881. EX-SUPERINTENDENT.

CASES OF HÆMORRHAGE AFTER THE EXTRACTION OF TEETH.

To the Editor of THE LANCET.

SIR,—I think the attention of dentists should be drawn to the many and serious cases of hæmorrhage that occur after the extraction of teeth.

During the last year my partner and I have been sent for to attend no less than six cases of this sort, in which nothing short of plugging the cavity sufficed to stop the bleeding. Such cases are sometimes really formidable, owing to the delay in sending for assistance, either from the impression that the hæmorrhage will soon cease spontaneously, or that some wash supplied by the nearest chemist will suffice.

I would suggest that dentists should satisfy themselves as to the complete cessation of bleeding in all cases of extraction before dismissing their patients, and should also give implicit directions about sending for professional aid without delay in the event of the recurrence of the hæmorrhage.—I am, Sir, yours faithfully,

Albion-street, Hyde-park-square, W., M. PRICKETT, M.D.
April 25th, 1881.

Dr. Wm. Thursfield.—We are sorry that our space will not permit us to publish the correspondence. It is strange that no communication has been received from the surgeon consulted, and this in two cases. We hope the remonstrance will be effectual.

H. S.—The disease is perfectly well known and recognised by medical men. Our correspondent should consult his own adviser and take his counsel in the matter.

UNQUALIFIED ASSISTANTS.

To the Editor of THE LANCET.

SIR,—Medical reform is the question of the hour of the nineteenth as it was of the eighteenth century medical world. I trust we shall have more success than our ancestors. Medical reform has a wide range. There is one aspect I should like to bring under your notice—viz., medical reform in its relation to the internal life of the profession. A short sketch of the inner economy of a certain section of the medical world in northern towns will certainly be novel, and may prove interesting to you. I wish to direct your attention to the following points.

A. We grumble at quacks and quackery, prescribing chemists, and others who violate the Medical Acts. Do we take into account the number of unqualified practitioners who are offending against the law inside the profession? In the small northern town from which I write there are twenty legally qualified practitioners, ten of whom have unqualified assistants. Some of the latter have been promoted from behind the counter of chemists' shops; some have spent a year or two at a medical school, and you meet them driving about with more than the airs of Fellows of the College of Surgeons of England. I need hardly say that these assistants are (1) violating the law; (2) imposing upon the public; (3) robbing the qualified men; (4) that their principals must almost necessarily commit actions liable to imprisonment—viz., signing certificates for deaths of patients they have never attended. The profession is said by some to be overcrowded. I deny it. There is work for all our qualified practitioners, but their place is usurped by those who have no right to practise, and whose employment is an injury and imposition upon the public. In addition to many excellent reforms proposed, I will add another—"that the abolition of unqualified assistants is imperatively demanded in the interests of the public and the profession."

B. You may ask how does it pay to keep unqualified assistants? In this wise. When a practitioner has more work than he can do, he engages for a wretched pittance one of these assistants, who keeps the books, makes up medicines, visits, and attends midwifery. The principal is thus able to do a larger practice and to handicap his qualified competitors. Unfortunately, owing to the want of education, the "doctor's man" goes down very well with the working classes. In a large practice low fees are charged, such as consultations at home and medicine, 1*s.* 6*d.*; visits and medicine, 2*s.* or 2*s.* 6*d.*; midwifery, 10*s.* 6*d.* to 15*s.*; clubs, 2*s.* 6*d.* or 3*s.* per head per annum. The assistant does a large share of this work. In a large practice of this kind there are, of course, a great number of bills to be sent out. A lower depth of degradation is reached in connexion with these bills. A "collector" is employed, to whom is entrusted the gathering in of a large number of these accounts. He calls round at the patients' homes weekly or fortnightly, and receives the money in instalments of 6*d.*, 1*s.*, 2*s.*, &c., until the account is paid off. If the collector finds any bad payers, the county court is resorted to, and the county court judge comes to the aid of the "doctor" (?) by making an order at the rate of so much—say 2*s.* 6*d.* per month. There is no trade conducted on such principles—no bootmaker, tailor, butcher, or baker would descend to such a method of conducting his business. I need hardly say that chemists have no necessity for such a method of payment; in fact, they smile at the professional men (?) who employ these collectors to gather in the money earned by their unqualified assistants, and chemists pride themselves on not having reached such a depth of degradation as to have to resort to such a practice. All the chemists here know the truths I am detailing to you. Internal reform in this direction is also needed. We want more of the professional spirit and more self-respect to put an end to such evils.

I am, Sir, yours faithfully,

April 14th, 1881. VERITAS.

MISSED LABOUR.

To the Editor of The Lancet.

Sir,—Seeing the discussion on "Missed Labour" in your journal, and thinking the following case may be of interest, I send it. I was asked by the clergyman of the parish to see a poor woman who was suffering, as he imagined, from an abdominal tumour. The history of the case was that the woman became pregnant, and distinctly felt the child up to the ninth month, when the movements ceased. The abdomen continued to remain in the same enlarged condition for six months longer, when I saw her, and diagnosed "missed labour." I ruptured the membranes, and twenty-four hours after she was delivered of a full-term child, having all the appearance of being in the uterus the time stated.

I am, Sir, yours, &c.,
Wareham, Dorset, May 10th, 1881. W. T. Boreham, M.D.

SPECIFICITY AND EVOLUTION IN DISEASE.

To the Editor of The Lancet.

Sir,—Your editorial comments on "Blood Diseases and the Germ Theory," in a recent number of The Lancet, induce me to send you the following reflections on the collateral question as to how far our commonly accepted notions of specificity of diseases should be modified by the doctrine of evolution.

This doctrine, which has so rapidly and entirely altered the face of the organic world, as we conceive it, has as yet made but a feeble impression, if any, on medical science and pathology.

The importance of the principle of specificity in disease has been clearly and generally recognised since the time of Laennec and Bretonneau; Trousseau, in one of his clinics devoted to the subject, remarks of specificity, "Elle domine toute la pathologie, toute la thérapeutique; en un mot, toute la médecine." And the same belief, tacit or avowed, would seem to pervade all modern medical literature.

Now, the argument upon which medical writers base their theory of specificity consists in an appeal to the analogy which exists between the natural history of diseases and the natural history of animals and plants. In the words of Sydenham, "Unaquæque mortorum non minus quam animalium aut vegetabilium species affectiones sibi proprias perpetuas ac pariter univocas ab essentia sua promanantes sortita est;" and until the last few years no better argument was possible.

Since, however, as regards the organic world, we have come to speak of an origin of species, and learnt to trace their differentiation under the influence of evolution to the eventual survival of the fittest, I would ask, should not our views concerning specificity of diseases undergo a similar modification? Is not the theory of specificity swallowed up in the larger theory of evolution? As with animals, so with diseases; may we not henceforth regard the several species and genera as descendants from a common ancestor? Starting from a non-specific inflammation or fever, may there not arise therefrom under favourable conditions an inflammation or a fever different from the parent stock, and capable of reproducing itself? I think so. Look at tubercle, a disease characterised by such well-marked features as to have been long since classed as a specific disorder, but whose natural history, revealed by the experiments of Cohnheim, Burdon-Sanderson, and others, shows that it may be derived by cultivation from the simplest common inflammation as that resulting from a chemical irritant; the non-specific has developed specific characters, the homogeneous become the heterogeneous. So it is with other diseases; even the ordinary stages of a common inflammation, pimple, vesicle, pustule, or scab, foreshadow and typify diseases which we call specific, wherein one or other of the stages predominate, while the rest are subordinate. The common ancestry of specific diseases once recognised would do much to remove the hard and fast line so often drawn between disease and disease in text-books and dissertations, but of which nature knows nothing.

I am, Sir, yours obediently,
W. J. Collins, B.Sc., M.R.C.S.
St. Bartholomew's Hospital, April 23rd, 1881.

420.—If our correspondent has not forgotten his letter of March, 1880, he can hardly be surprised that we should hesitate to accept as entirely accurate the statements contained in that of April 11th. If they are correct, we believe that a representation to the authorities of the injustice involved in the course complained of would meet with proper attention.

Notice.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "The Lancet General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in The Lancet.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

A Lecture
ON THE
PHYSIOLOGY AND PATHOLOGY OF THE OLFACTORY NERVE.

Delivered at the Hospital for Epilepsy and Paralysis, Regent's-park.

By JULIUS ALTHAUS, M.D., M.R.C.P.,
SENIOR PHYSICIAN TO THE HOSPITAL.

(Concluded from p. 773.)

If odorous substances are to be perceived, the nose must not be dry, for it is the nasal mucus which absorbs odoriferous molecules from the atmosphere, and brings them in contact with the olfactory cells. Anything that tends to check the secretion of mucus, such as extremes of heat and cold, the inspiration of dusty air, and the first stage of a cold in the head and the nose, will cause diminution or loss of smell. Persons who have habitually a dry mucous membrane can only smell well when there is a great deal of moisture in the atmosphere. But there must be no excess of mucus, which is equally prejudicial to olfaction. This is seen in the second stage of a cold, when the membrane is swollen and in a state of hypersecretion. Too much mucus not only prevents mechanically the access of odorous particles to the terminal branches of the nerve, but also macerates the olfactory cells, whereby the excitability of the nerve is diminished. Sneezing and blowing the nose may, under such circumstances, restore smell by clearing away a physical impediment.

In ordinary quiet breathing only little air enters the olfactory channel, for most of it passes through the posterior nares into the pharynx. If we, therefore, intend to smell keenly, we instinctively resort to the use of either the dilator muscles of the nose, whereby the passage is enlarged, or of the compressors, by means of which we sniff. The latter way is even more effectual than the former, for during sniffing the agger nasi is squeezed against the septum, and the respiratory channel is closed, so that the air is obliged to pass through the narrow groove leading to the olfactory cells. In facial palsy from disease of the portio dura the dilators as well as compressors of the nose lose their power, which is the reason why smell is lost in that affection on the side of the lesion.

The sense is also impaired or lost in chronic inflammation and thickening of the membrane, whereby the olfactory channel is obstructed; and in polypus, other tumours, and foreign bodies in the nose. Adhesion of the soft palate to the posterior wall of the pharynx has the same effect; a free incision into the palate will, in such cases, restore the smell at once.

The specific stimulants of the olfactory nerve are odorous substances, which must be either in the form of gases or capable of being changed into gases. Such substances give off exceedingly minute particles, which form a kind of atmosphere, the density of which diminishes in proportion to the distance from the substance. These particles, on coming in contact with the olfactory membrane, cause a peculiar vibration in the molecules of the nerve, which is transmitted to the olfactory centre in the brain, where it is appreciated.

A classification of odours is very difficult. Haller, the great physiologist, distinguished them into pleasant and unpleasant; but this appears unsatisfactory, as some people detest odours which are relished by others. The smell of assafœtida is horrible to most of us, yet it was used as a perfume by the ladies of the Roman empire; and in Afghanistan, from where it comes, it is called "scent for the gods." The Siamese are said to be fond of the smell of rotten eggs, and sportsmen enjoy the smell of the stable. The division of odours into mineral, vegetable, and animal is likewise not a good one, for the odour of musk is found not only in the animal Moschus moschiferus, but also in the plant Rosa moschata, and in some earthy substances; Japanese teapots are impregnated with it. The best classification appears to me that which has been proposed by Frölich, who distinguishes odours acting purely on the olfactory, such as essential oils, resins, and balsams; and others acting likewise on the fifth nerve, such as iodine, bromine, chlorine, nitric and acetic acids, ammonia, horseradish, mustard, &c. The former act simply as odours, while the latter irritate the mucous membrane of the eyes, nose, and throat, and cause lacrymation, sneezing, and coughing.

Professor Tyndall has struck out a new line of research by investigating the effects of odours on radiant heat, which he has found to be a more refined test than any other. Assuming the absorption of one atmosphere of dry air as unity, he found that perfumes intercepted many times the quantity absorbed by the air, and that the rate of absorption varied from 30 for patchouli to 372 for aniseed, intermediate numbers being found for sandalwood, geranium, oil of cloves, attar of roses, bergamot, neroli, lavender, lemon, portugal, thyme, rosemary, oil of laurel, camomile flowers, cassia, and spikenard. Thus, it was shown that—

> "The sweet South,
> That breathes upon a bank of violets,
> Stealing and giving odour,"

owes its sweetness to an agent which, although almost infinitely attenuated, may be more potent as an intercepter of terrestrial radiation than the entire atmosphere from "bank" to sky.

That the olfactory nerve is sometimes *congenitally absent* has already been noticed. Breschet has seen this peculiarity to run in a family. The patient under his care had inherited it from his father; he had an aversion to flowers, and disliked to see them on the person of a woman. He had an antipathy to gardeners and botanists; yet he was able to perceive the emanations from cesspools—namely, ammonia and sulphuretted hydrogen, and he was in the habit of taking mustard and snuff.

We know *atrophy* to be a common affection of the optic nerve; indeed, this is one of the principal amongst the early symptoms of locomotor ataxy. The same pathological process appears occasionally to invade the olfactory, more especially in the aged, where smell is impaired or lost, and sclerosis of the nerve has been discovered after death. This wasting appears to affect chiefly the external root, which is traced to the fissure of Sylvius, and which seems to be more important for olfaction than the middle or internal root.

Loss of pigment in the skin of the body has been noticed by Dr. Hutchison, of Kentucky, in a negro boy, to coincide with loss of smell; and this case has provided Dr. W. Ogle with a text for remarks on the importance of pigment for olfaction. We have already seen that the presence of colouring matter in the olfactory cells is really dependent upon the integrity of the nerve, and that after destruction of the latter the pigment disappears. It is therefore more in consonance with physiological facts to assume that this absence of pigment is not of itself a cause of anosmia, as Dr. Ogle would lead us to believe, but simply a consequence of withdrawal of nervous influence. Anosmia and loss of pigment have therefore to be looked upon as symptoms of a pathological condition, but do not stand in the relation of cause and effect.

I lately had an illustrious person under my care who is an Albino, and devoid of colouring matter in the hair and iris. In early life he had had great difficulty in reading, and had been warned by oculists whom he had consulted that he would lose his sight altogether if he continued to read much. He eventually constructed for himself a very simple and ingenious contrivance by means of which the rays of light were made to fall on the retina through an exceedingly minute aperture; and with this little instrument he has managed for many years to read all day long without fatigue. His smell and taste had never been very keen; and when he was about sixty-three years of age he lost them altogether. No accident or other obvious cause had given rise to this affection, and I therefore looked upon it as ultimate atrophy of a nerve which had never been highly developed, and consequent complete loss of any small quantity of pigment which might previously have been present in the sensorial cells of the nerve.

Injury to the head may give rise to anosmia from rupture of the olfactory nerves as they pass through the foramina of the ethmoid bone. In this place the nerves are exceedingly soft, and therefore particularly liable to be torn, while in the nose they have more power of resistance, from being invested with a sheath which is a continuation of the dura mater. The brain matter adjoining these nerves may therefore, on account of its greater firmness, escape laceration, so that the only symptom after an injury to the head may be loss of smell. It seems singular that it should generally be a blow or fall on the *back* of the head which causes rupture of these nerves, as they are situated in front. The injury acts, indeed, more by contrecoup than by direct violence; and that the anterior portion of the brain should be more liable to suffer in this way than the posterior is owing to the fact that the former is situated directly on the depressed and elevated surfaces of the cranial bones, which here present great irregularities in their shape, while the posterior lobes rest on a soft cushion, the tentorium cerebelli, whereby they are effectually protected.

Excessive stimulation may temporarily or permanently destroy the excitability of the olfactory nerve. It is related of Marshal Richelieu that he habitually lived in an atmosphere of the strongest scents, which made his visitors quite ill, while he was himself ultimately quite unaware of them. Scavengers, dustmen, and tallow-boilers become after a time insensible to the disgusting odours surrounding them, anatomists to the smell of the dissecting-room, and patients suffering from cancer to the emanations from their sores. But even true anosmia, or insensibility to *any* odorous substances, may thus be produced. Graves has recorded the case of a captain in the Yeomanry, who in the Irish rebellion of 1798 had to superintend the work of emptying out an old cesspool which was filled with the offscourings of the market and all manner of filth, and on the bottom of which 500 pikes were reported to have been concealed, and were actually discovered. He was all this time exposed to most abominable effluvia, and suffered greatly from the stench. Next day he found that he had entirely lost his smell, and thirty-six years afterwards, when Graves examined him, the anosmia still persisted. A similar thing happened to a surgeon at Bremen, in Germany, who had to make the post-mortem examination of an archbishop who had died of cancer of the stomach. The fearful emanations arising from the body of this dignitary of the church destroyed the surgeon's smell for life. Such cases are analogous to those of blindness from exposure to a too intense light, and deafness from explosions at close quarters. The pathology of these conditions has not yet been investigated, but I deem it probable that they are owing to capillary hæmorrhage in the nerve.

Inflammation of the olfactory nerve would appear to be an exceedingly rare occurrence, which seems singular if we consider the frequency of optic neuritis. The latter occurs almost invariably when the intracranial space is reduced by tumours, but such a condition does not seem to affect the first pair in a similar manner. The only case of acute olfactory neuritis which has as yet been placed on record occurred in a patient who was some years ago under my care at the hospital, and who suffered from an advanced stage of locomotor ataxy. He was a banker's clerk, aged forty-eight, married, and father of two children, and had been in good health until eight years before admission, when, apparently from having been exposed to cold draughts at his office, he began to feel numbness in his feet, and in walking it seemed to him as if he was treading on india-rubber or cotton. About the same time he was startled by perceiving a strong smell of phosphorus, which never left him for six weeks, and overpowered all other accidental smells. At the end of that time he noticed that he had become entirely insensible to odours of any description. I tested the patient with camphor, valerian, ether, opoponax, and a variety of other strong scents, none of which he was able to perceive. When allowed to sniff ammonia he experienced the usual sensations of tickling in the nose, choking and lacrymation, and snuff made him sneeze. The nasal twigs of the fifth nerve and of the spheno-palatine ganglion were therefore shown to be in their normal condition. The patient tasted sugar, salt, quinine, and acids, but the perception of flavours in eating and drinking was entirely gone. When his eyes were bandaged he was unable to distinguish between stewed onions, apples, and turnips which were given him, but he could tell the difference between roast beef and mutton by the tactile sensibility of the tongue. He did not perceive the flavour of wine; claret tasted to him like weak vinegar and water, and port wine as spirits and water. The patient died of collapse some months after admission, and Dr. Ferrier, who was then my colleague at the hospital, made the autopsy. There were found the naked-eye appearances of neuritis of the first pair at the base of the brain, and the specimens were removed and handed for microscopic examination to the late Dr. Lockhart Clarke, who was then likewise physician to the hospital. Unfortunately that gentleman died soon afterwards, and I have not been able trace the specimens, which is much to be regretted in a ca of such extreme rarity. That this, however, really was case of acute olfactory neuritis seemed evident from t symptoms which were observed during life. There was first a stage of sensorial hyperæsthesia which, after havi lasted for six weeks, merged into complete anæsthesia of t special sense. This corresponds closely with what I ha observed in neuritis of the fifth nerve, where there is likewi a first stage of hyperæsthesia, as evidenced by severe pain the parts supplied by that nerve, and lasting for five or s weeks, after which complete anæsthesia of the face a motor paralysis of the muscles of mastication set in. Th perception of the smell of phosphorus, which this patient ha had for six weeks consecutively, I attribute to the circu stance that the olfactory nerve responds to stimulation othe than by special odoriferous substances, by perception of thi peculiar smell. I have already spoken of this sympto when treating of the galvanic excitability of the nerve, an the case just related seems to show that it is also caused b irritation of the nerve through hyperæmia and inflammatio similarly as in retinitis flashes of light are perceived by th patient.

I have reason to believe that *chronic olfactory neuritis* leading to loss of smell, occurs in syphilitic patients, togethe with affections of other nerves at the base of the brain.

Tumours growing at the base, and irritating or destroyin the first pair, will cause, first, hyperosmia, and afterward anosmia. Lockemann has described the case of a woma who complained of horrible smells which nobody else coul perceive, and also suffered from vertigo and epileptifor convulsions. The smells ceased after a time, and it the appeared that the patient had lost the faculty of smelling o the left side. The other symptoms gradually increased i severity, and the patient died. On inspection a sarcomatous tumour was discovered in the left frontal lobe of th brain, which had completely destroyed the olfactory tract o the same side.

Finally, disease of the *olfactory centre* in the brain ma unduly exalt or destroy smell. That such a centre exist had been suspected for a long time, and pathologists sough it near the fissure of Sylvius and the island of Reil, and i close proximity to Broca's convolution, for anosmia has bee found associated with aphasia and right hemiplegia fro embolism and hæmorrhage. In such cases the loss of smel is unilateral, and confined to the side of the lesion. W have therefore right hemiplegia and left anosmia. Thi apparent discrepancy is satisfactorily accounted for by th circumstance that there is no decussation of the olfactor paths in the anterior commissure which joins the temporo-sphenoidal lobes, and smell is, therefore, appreciated on th same side on which it is perceived. Experimental physiolog has gone a step further in localising the seat of the olfactor centre more definitely. Dr. Ferrier finds it in the tip of th temporo-sphenoidal lobe, or the subiculum cornu Ammonis which appears likewise to contain the gustatory centre Faradisation of this part in animals is followed by a sniff which is evidently the outward expression of the excitatio of subjective olfactory sensations. Destruction of this par seems to cause loss of smell, and Ferrier's view is supporte by the circumstance that this structure seems to be particularly developed in animals which have a very keen sense o smell. Yet Munk, who has likewise investigated the relations of the cerebral cortex to the special senses, has com to entirely different conclusions, so that the question mus still be considered to some extent an open one.

Diseases of the olfactory centre have not yet been muc studied. It seems rational to assume that the hemi-anosmi of hysterical women, which is part and parcel of the hemi-anæsthesia from which they are so apt to suffer, is owing t a neurosis of this centre. The olfactory hyperæsthesi which is so frequently seen in certain forms of insanity hysteria, and as a premonitory sign of epileptic attacks, n doubt arises from undue excitability of the nerve-cells in th olfactory centre, which gradually spreads to the cells of th motor convolutions and tracts, and ends in a convulsiv epileptiform seizure.

The *treatment* of anosmia and hyperosmia remains to b considered. Of course, where the nerve is torn or destroyed we cannot hope to remedy the mischief which has been done yet cases occur from time to time in which treatment may b useful. There are two medicines which have a decided an antagonistic influence on olfaction—strychnia will exalt while morphia will impair and deaden it. Strychnia applie locally to the mucous membrane of the nose as a snuff, or taken internally in a suitable dose, wonderfully increases the keenness of the sense, the local application being the more effective of the two. Smaller quantities of scents are perceived, and their impression is more precise and pleasant. The sensitiveness to pungent odours is so much increased that snuff, ammonia, and acetic acid cause positive pain. It therefore appears that the excitability of the fifth nerve is likewise exalted. Morphia, on the other hand, has only insignificant effects when applied as a snuff; but if taken internally, and more especially if injected subcutaneously, confuses the appreciation of odours to such an extent as to produce a kind of chaos. Smell is not actually destroyed, but the odours appear, as it were, at an enormous distance, although the bottle containing them may be held right under the nose. The olfactory nerve is, in fact, narcotised.

Most other medicines which have an influence on olfaction act indirectly, and do so by altering the condition of the fifth nerve. Thus atropia and daturine cause great dryness in the mucous membrane, more particularly when injected subcutaneously. This interferes with smell, as has been pointed out above. The effects of pilocarpine on olfaction have not yet been studied, but will most probably be found antagonistic to those of atropine.

In anosmia I therefore prescribe one-twenty-fourth of a grain of strychnia mixed with two grains of powdered sugar, to be used as a snuff twice a day; and I increase the dose to one-sixteenth and one-twelfth of a grain should no effect be produced. In the hyperosmia of epileptic patients, when preceding attacks, I inject one-sixth of a grain of the acetate of morphia with one-sixtieth of a grain of the sulphate of atropia subcutaneously. This soothes the explosive tendency of the nervous centres, and acts as a preventive of epileptic attacks.

Electricity has been recommended by Erb and others for the treatment of anosmia; but as I have shown that the first pair is only influenced by a current of extreme power which would do harm in other ways, I warn you against the use of such a remedy for such a disease. Where syphilis is suspected or recognised iodide of potassium should be given.

In conclusion, I must say a few words on the *diagnostic importance* of certain smells in the sick-room, which was formerly much insisted upon; indeed, whole treatises have been written on the recognition of disease by sniffing. Dr. Heim, who was the popular physician of the day at Berlin some fifty years ago, recognised measles, scarlet fever, and small-pox by their peculiar smell on first entering a house, and before having seen the patient. Mr. Bernard of Upton Park has recently recorded in THE LANCET two cases of small-pox in which the patients themselves perceived a dreadful smell, apparently just at the moment of being exposed to contagion; and one of them when suffering from the eruption said that his perspiration had the same smell as that which made him sick before. When attending Skoda's clinique in Vienna, twenty-five years ago, I noticed that this celebrated teacher was in the habit of sniffing when approaching the bedside of patients suffering from the last stages of pneumonia, phthisis, typhoid fever, &c.; and he would give a bad prognosis when he perceived what he called the "cadaverous smell." Mr. Crompton of Birmingham has noticed a peculiar earthy smell from the body a week or a fortnight before death, which, he says, has never deceived him—an appropriate illustration of the saying, "Earth to earth." Dr. Begbie distinguished typhus and typhoid fevers by the sanguineous (others call it "mousey") smell of the former. Professor Parkes has noticed a peculiar odour in the skin of cholera patients. A pungent smell in the chamber of a lying-in woman shows that lacteal secretion is well established, while an ammoniacal smell has been said to indicate the approach of puerperal fever. Many women emit a peculiar odour while menstruating, which resembles a mixture of blood and chloroform; and this is believed to arise not so much from the discharge as from the more pungent character of the sweat secreted in the axilla. Persons of costive habit have a fæcal smell; and this is also often noticed in hypochondriacs and lunatics. In uræmia, whether owing to kidney disease or to severe retention of the urine, a urinous odour is emitted by the body; and the presence of pus in some part of the body has been recognised by a peculiar warm-milky smell of the patient.

Apart from the odour of the sick-room and the body generally, the smell of the sputa, urine, fæces, sweat, ulcers, &c., was carefully noted by the older practitioners, and utilised for prognosis and treatment. Unquestionably there was much that was fanciful in such ideas; but occupied as we are at present with the study of more precise and definite symptoms, we have, perhaps, gone to the other extreme in neglecting such signs altogether. Everybody has his own special odour, and this varies according to the circumstances of life, the food taken, and the state of health in which he happens to be. That it should be altered in disease, and that special diseases should have special odours, is only what one would expect; yet the increase of cleanliness and ventilation has no doubt done away with a large variety of smells which formerly used to assail the nostrils of the physician.

Are odours of any medicinal value? This may well be doubted. The vapour of hellebore has been used for purging, that of crocus and hops for procuring sleep, and the emanations of burnt feathers and wool for combating hysterical fits; but no doubt the imagination was largely influential in the production of any such effects. Chloroform, ether, ammonia, and similar substances, which have a definite physiological action, can hardly be looked upon as odours. On the other hand, it is certain that strong scents may be hurtful, more especially the sweet ones, such as those of lilies, violets, narcissus, nerium, oleander, and lobelia; and these, again, chiefly in nervous and hysterical women, in whom headache, dizziness, fainting and convulsive fits have thereby been caused. Yet we would hardly go so far as Pope, who considered it within the bounds of female delicacy to

"Die of a rose in aromatic pain";

or the German poet Freiligrath, who in his beautiful stanzas, "Der Blumen Rache," makes the spirits of flowers torn from their beds rise in the night and kill the maiden to whom they had been offered:

"Blumenduft hat sie getödtet!"

Indeed, we may safely rely on being able to combat any of the accidents or symptoms just mentioned by a very simple expedient—viz., opening the window.

A STUDY OF THE PATHOLOGICAL PHYSIOLOGY OF CONTRACTURES.[1]

BY DR. CHAS. RICHET.

IN order to become thoroughly acquainted with the physiology of muscle, it is necessary to study the morbid phenomena it exhibits, for physiology and pathology lend each other mutual support, each with its different method arriving at the same result—viz., the knowledge of the properties of muscular tissue and its relations with the nervous system. Let us, in the first place, refer to that physiological phenomenon described by M. Tiegel, under the name of *contracture*. If a fresh muscle, stretched by light weights, be stimulated, and if the stimulus be very strong, the contraction is continued for a very long time. Instead of having a simple shock analogous to that which is figured in all the classical works, where relaxation is nearly as rapid as contraction, there will be a very sudden contraction and a very slow relaxation; often, indeed, the relaxation will be *nil* and the state of contraction persist indefinitely. Again, certain muscles, when stimulated for a long time by powerful induction currents, are not relaxed, and remain contracted even when the stimulus has entirely ceased. This form of contraction thus passes into cadaveric rigidity. There is no intermediary between contraction—the active phenomenon, and rigidity—the phenomenon of the death of muscle.

But these facts cannot so far serve to give a definition of the pathological phenomenon of contracture. It is likely that there is a relation between these physiological contractures, produced by strong stimuli, and the contractions seen in certain patients; but it is as yet hypothetical to frame an analogy, and it is not suitable to introduce these physiological ideas into the definition of contracture. We may define it as a state of shortening of the muscular fibre which can no longer be relaxed by the influence of the will. In saying muscular fibre, we imply that retractions due to sclerosis must not be included with contractures, for the former are fibrous indurations, such as we observe in certain cases of chronic myositis, where there is a shortening of the whole muscle. Let us first examine in what cases contracture is observed.

---

[1] Lecture delivered at the Paris Faculty of Medicine: Auxiliary Class of Physiology.

In cerebral or medullary affections there is contracture when the lesion is seated in certain motor regions of the cord. The important works of M. Charcot and of his pupils, especially Brissaud,[2] have determined in what cases these contractures are produced. In hemiplegia there are primary contractures, due probably to cerebral compression, and late contractures, due to degenerations of the cord. This degeneration involves the pyramidal fasciculus. In lateral sclerosis there is also observed a lesion in the white columns of the cord which determines the contracture. Thus, certain medullary lesions can provoke contracture, either of a limb or of one side of the body. It is probable that it operates not by suppression of action, but by irritation. It is because the cord is excited that the muscle can thus contract. Contracture is the analogue of hyperæsthesia; when the motor part of the cord is excited there is contraction; when the sensory portion, there are pain and hyperæsthesia.

Contractures are met with in many other diseases of the cord, and may all be explained in the same manner; the exaggerated excitability of the cord leads to contracture of the muscles. Somewhat analogous phenomena may be obtained experimentally on animals. Yet it is not simply by acting on the cord, but by stimulating certain parts of the brain, either the ventricles, as M. Cossy has done, or the cerebral cortex as MM. Rochefontaine and Viel, that contractures are obtained, transitory, it is true, but sufficient to establish the alliance between the facts of experimentation and those of pathology.

To sum up, we have a first series of contractures due to inflammation (chronic or acute) of the cord or the brain.

There is a second physiological process by which contractures are established. In the normal state there is a direct synergy between certain sensory nerves and certain muscular nerves, so that the stimulation of the sensory nerve provokes in the cord an immediate reflex on the motor nerves of the muscle. This hypothesis, which J. Müller propounded at the outset of the study of reflex movements, has been confirmed by a multitude of observations. Thus, the sensory nerves of mucous membranes, when stimulated, provoke contraction of the muscles adjacent to these mucous membranes; the conjunctiva, for example, when touched excites a reflex of the eyelids. Suppose that there has been on one of these mucous membranes a constant stimulation, as that which is produced by a burn or ulcer, there will then be a tendency to contraction of the orbicular muscle, as, in fact, is seen in a large number of cases. One knows that ulcerations of the conjunctiva determine spasm of the orbicularis; ulceration of the ureter a spasm of the muscular membrane of this canal; fissures of the anus a contraction of the anal sphincter, &c. Caustic injections into a joint of a guinea-pig or of a dog determine contracture of the muscles bordering on the joint. M. Valtat has made some exact experiments bearing on this, and he has seen arthritis determine firstly contracture, then atrophy of the muscles. Even on the cutaneous surface a painful stimulus may give rise to a kind of contracture. That is seen on the lower limb following ulcers &c. These latter facts establish a natural transition between contracture properly so called and the other varieties of spasm or convulsion of muscle (tetany, local tetanus, &c.). Inflammation and traumatic irritation of nerves produce contracture by the same mechanism—viz., by over-exciting the reflex activity of the cord.

We have then a second variety of contracture—contracture due to a prolonged peripheral stimulus.

There is a third class of contracture, observed in hysteria, and also beyond every morbid state in certain physiological or individual conditions. In hysteria there is very likely an increase in the activity of the cord, together with an abeyance of action of the higher nerve centres. Physiological experiments have shown that in separating the cord from the brain reflex medullary action is over-excited, as if there were in the brain moderating centres of reflex actions. Again, among hysterical subjects contractures are very frequent. So are they in the somnambulic state, which in so many points resembles hysteria. Hence this third class of contractures, which depend on an absence of action of the central nervous system.

In all cases the muscle may be contracted when the cord becomes over-excited. It is then a manifestation of the exaggerated activity of the cord, and it is necessary to study this condition with more detail.

It is admitted that in the normal state the muscle is linked to the nerve-centres by two kinds of nerves—a centrifugal motor nerve and a centripetal sensory nerve. These two nerves reach probably a very limited region of the cord, and the reflex from one to the other is very readily accomplished. All occurs as if there were a sensory nervous current constantly passing up to the cord from the muscle to determine a reflex on the same muscle. The descending nervous influence towards the muscle puts its tonicity into play. One knows that when the nerve of a muscle is cut the muscular fibre is relaxed (Brondgeest), and that its chemical actions diminish, so that the venous blood becomes redder (Claude Bernard). Suppose, then, that the cord is over-excited, the tonicity will have another character. Instead of being a state of semi-relaxation of the muscle it will be its prolonged contraction—in other words, its contracture. Thus the tonicity of the muscle is sometimes *nil*, as when all the nerves are cut; sometimes normal, as in the healthy individual, where there is a harmonious equilibrium between the different antagonistic muscles; sometimes exaggerated, as in hemiplegia and hysteria. Ultimately we reach this conclusion for the cause of contracture, that it is the state of exaggerated tonicity of the muscle.

One may demonstrate readily that of all the sensory stimuli which can provoke contraction by reaching the cord, it is the sensory excitation of the muscle itself which is most apt to determine contraction. Every strong muscular contraction is a sensory excitation of the muscle. Thus, in hysterical subjects it is sufficient for them to make an energetic movement in order to produce a contraction. The muscle which has been strongly contracted can no longer be relaxed, and remains contractured. The same result is attained by kneading, or exerting strong pressure on the muscular fibres. In the hypnotised, even in the first degree of somnambulism, the aptitude to contracture is quite as marked. Some individuals, even apart from the hysterical or somnambulic state, are subject to contractures or cramps consecutive to a rather feeble muscular contraction. That is doubtless a question of a more than ordinary medullary excitability. In the researches which I have undertaken with M. Brissaud upon this subject, we have found that excitation of the tendon had a directly opposite effect to contraction of the muscular fibre itself. Palpation of the muscle determines contraction, but palpation of the tendon determines its relaxation. Thus, the strongest contractions provoked are relaxed as one palpates more or less strongly the tendon of the contractured muscle. It all takes place as if the tendinous nerves were nerves of arrest, serving by an inhibitory action to make the contraction of the muscle cease.

The physiological state of the contractured muscle may be ascertained by different methods of investigation. If we introduce fine needles into the muscle and ascertain its excitability during relaxation on the one hand, and on the other during contraction, we do not ascertain notable differences. But if we try to take a myographic tracing of contractured muscles, we see that in spite of its extreme shortening the muscle excited by electricity can still shorten. Contracture is not then the maximum of shortening of the muscle, and the myographic line of the tracing occupies a level intermediate to contraction and flaccidity. Another method of exploration is founded on that very old idea of physiology, that the irritability of a muscle is only called forth if the muscle is traversed by oxygenated blood; whether the lack of oxygen or the products of denutrition accumulated in its tissue exert a baneful action on its contractility. Now, if we completely anæmiate a limb by applying methodically around it Esmarch's elastic bandage, at the end of five to six minutes the contracture will disappear; voluntary movements will be longer preserved, and at the end of about half an hour they will have disappeared. The electrical excitability only ceases at the end of an hour and a half. Thus there is in the excitability of the muscle this gradation—that excitability to contracture disappears the first; then excitability to voluntary movements; then excitability to electric action. If we remove the bandage from the muscle thus relaxed, immediately the blood flows into the muscle the contraction will return with as much if not more force than before. There was, then, in the relaxed muscle a true latent contraction. Whatever may be the explanation of this paradoxical phenomenon, we think that it indicates with sufficient exactitude this fact, that the muscle was strongly excited by the motor nerve and the cord; and that if it did not respond to this excitation by a contraction, it is because being deprived of blood, it could no longer become contractured. One may then say that this anæmiated muscle, not responding to neuro-medullary excitation, was in a state of *latent contracture.*

---

[2] Recherches Anatomo-pathologiques et physiologiques sur la Contracture permanente des Hémiplegiques. Paris, 1880.

In hemiplegia the application of Esmarch's bandage dispels the contracture, as in hysteria. In certain cases, however, where there are old deformities or fibrous retractions, the limb does not return to its primitive position. By another mechanism chloroform makes contracture disappear—viz., by abolishing the activity of the cells of the cord. It is difficult to say if contracture is an active or passive state of the muscle. Researches have been made, but they are not very conclusive. M. Onimus fancied that he had been able to establish this distinction between the active or passive state of the muscle on the following grounds. If two needles in communication with a galvanometer be introduced into two healthy muscles at rest, the needle of the galvanometer undergoes no deviation; if one of the muscles contracts, it will become negative in relation to the muscle at rest, which is positive, and a current will be established, causing a deviation of the galvanometer. Now, a contractured muscle does not present this phenomenon. The observation of M. Onimus does not seem to me very well founded, for it is a change in the electric state which makes the galvanometer deviate, and this change can only take place if there is a change in the physiological state of the muscle.

Brissaud and Boudet by employing the myophone have found that the contracted muscle produces a rolling bruit (rotatory bruit, muscular sound), whilst the contractured muscle only produces a very weak and irregular bruit. It seems that the muscular fibres contract, the one after the other, incessantly reinforcing each other; some stronger, others weaker.

Brissaud and Reynard have also sought to establish if there was by the effort of contracture an increase of temperature; and, instead of finding hyperthermia, as in every strongly contracted muscle, they have found rather a diminution of temperature by some tenths of a degree in the contractured muscles of hemiplegics.

The argument has also been raised that the muscle cannot remain contracted for more than half an hour without there being enormous fatigue, and yet we see contractures persist almost indefinitely without the patient experiencing the least lassitude. In truth, that does not prove the passive state of the muscle; it only indicates that in voluntary contraction there is an effort which fatigues. We do not yet know the cause even of this fatigue. The experiments of Ranke in injecting lactic acid are nothing less than convincing in attributing the cause of muscular fatigue to an exaggerated acidification of the muscle. If, then, there is no fatigue in contracture, it is very probably because of the absence of voluntary effort much more than on account of the passivity of the muscle.

The analysis of different physiological states of the muscle, which are like transitions between the normal state and the state of contracture, may help us perhaps to define the state of the muscle.

Catalepsy is a feeble contracture. Once contracted, the muscle is no longer relaxed; but whilst there must be a very great force to overcome the resistance of a contractured muscle, a very feeble force suffices to conquer the resistance of a cataleptic muscle, and catalepsy might be defined as a feeble contracture.

Let us refer to the definitions given by physiologists of the physical properties of muscle. They have distinguished extensibility — viz., the property of being stretched by a weight; and elasticity, the property of returning to the normal position after the removal of the weight.[3] Thus a normal muscle is extensible and elastic. But if we divide its nerve, in consequence of the suppression of nervous action the muscle becomes more extensible. When we destroy the tonicity of the muscle, we increase its extensibility. The contractured muscle, on the contrary, has a minimum extensibility, and the heaviest weights can no longer stretch it; in other words, its elasticity is very strong. As to the cataleptic muscle, its extensibility is weak, but its elasticity is *nil*—in this sense, that after having been removed from its primary position it can no longer return to it. We may, then, from a purely physical point of view, define contracture to be a state of the muscle in which the extensibility is weak or *nil*, and the cataleptic a state of the muscle in which the elasticity is weak or *nil*. In truth, that does not indicate whether during contracture there is an active or passive state of the muscle; we do not know this in the case of normal contracture—how could we then know it in the case of a pathological phenomenon?

---

[3] M. Marey calls extensibility what physicists designate feeble elasticity. A very extensible muscle is a feebly elastic muscle; but these terms, feeble or strong elasticity, complete or incomplete, serve to confuse those who are not familiar with the physical sciences.

NOTES ON ABSCESS OF THE LIVER.

By Surgeon-Major M. C. FURNELL, M.D., F.R.C.S.,
SANITARY COMMISSIONER, MADRAS; LATE SENIOR PHYSICIAN, MADRAS GENERAL HOSPITAL.

I VENTURED in THE LANCET of November, 1878, to express my opinion of the superiority of opening abscesses of the liver by incision, followed by the use of trocar and cannula, especially if accompanied by antiseptic precautions, over the aspirator, and I strengthened the opinion thus expressed by giving some cases. I now add a few more.

CASE 1.—R——, aged forty, a brass-smith, admitted on May 28th, 1878; an emaciated man, of intemperate habits, with a round swelling, occupying the whole of the right half of the abdomen, descending as far down as the iliac fossa, said to have gradually enlarged for the last ten days. The patient states that about five days before the swelling appeared he had an attack of fever which left him as soon as the tumour made its appearance. The tumour is about the size of a cocoa-nut, and no pulsation can be felt in it, neither can any bruit be heard. I will omit for brevity sake the systemic examination as given in the case-book.

May 29th, 1878.—The patient is much in the same condition this morning; pulse slow and feeble; respiration hurried; fluctuation in swelling distinct; it was, consequently, determined to evacuate the abscess. The patient was placed under chloroform, when an incision was made immediately below the right costal cartilage, and a large trocar introduced, giving exit to about twenty ounces of purulent stinking fluid. The wound was kept open by a strip of lint, steeped in carbolic oil, introduced through the cannula before its withdrawal, and the wound dressed antiseptically. It would take up too much space to give each day's entry; suffice it to say the man recovered without an untoward symptom, gained flesh and strength, and was discharged quite well on June 22nd.

CASE 2.—A. H——, Esq., a coffee planter, admitted July 29th, 1879. History: Came to India in 1863, and enjoyed good health until 1869, when he was attacked with inflammation of the liver, which ended in abscess; for this he was sent home and the abscess was opened by Sir Wm. Jenner, and he made a good recovery. There is puckered cicatrix in the epigastrium, but the patient states that although his medical attendants in this country said it was an hepatic abscess, the distinguished physician who opened it in England was not of that opinion. Whatever it was he completely recovered, and came out again to this country. In 1875 he again was obliged to return to England, this time on account of some injury to his eye. He returned to India, and early in 1876 he suffered from malarial fever and hepatic congestion, from which he recovered. He remained fairly well until May, 1879, when he suffered from an acute attack of dysentery which was followed by acute lancinating pain in the right hypochondrium, accompanied by shivering fits, fever, and night sweats. He treated himself with calomel and counter-irritants; but obtaining no relief, he applied to Dr. Benson at Shimoga, who sent him on to the General Hospital, Madras. His state on admission, as taken from the hospital note book, was as follows:—

Circulatory system.—Extent of cardial dulness normal; heart's sounds natural, action regular; pulse 62 per minute.

Respiratory system.—Thorax well developed; expansion equal; respiration slow, full sixteen per minute. Nothing abnormal detected on percussion or auscultation.

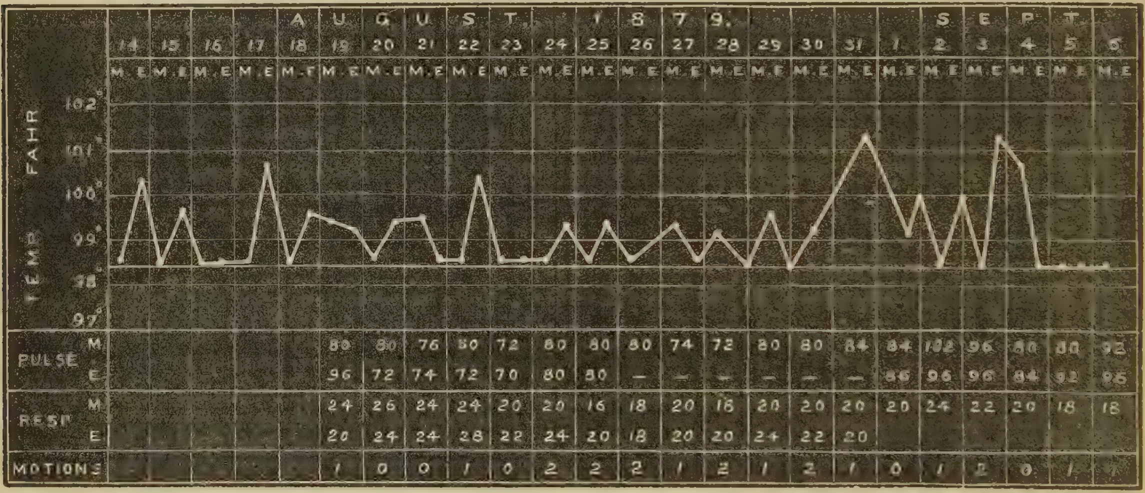
Nervous system.—Patient complains of pain in the right hypochondrium, increased on pressure or when patient lies on his right side; sleeps fairly at night.

Digestive system.—Tongue slightly furred, white; appetite fair; bowels moved thrice in the twenty-four hours, motions loose; splenic area normal; area of hepatic dulness extends from the sixth rib to two inches and a half below the costal margin; there is a slight bulging in the right hypochondrium, tenderness on pressure; no fluctuation can be detected.

Integumentary system. — Skin cool and moist; slight œdema over swelling in hepatic region; temperature normal morning and evening on day of admission. Treatment: The nitro-muriatic acid mixture, foot-baths, and pads to side.

I attach his chart, from which it will be seen that the patient did well for sixteen days after admission—that is, there was no hectic fever, the appetite was good and the usual functions of the body were normal in action. The patient was about, and went out in the evening in a carriage. There was no indication for any surgical interference, and he was strongly recommended to proceed to England. This, however, he declined to do. On Aug. 13th, he complained of slight pain in the swelling, and more especially when lying on the left side; temperature normal. Next day the pain was worse, and the temperature went up to 100°. He admitted having dined well, and taken a fair share of wine a night or two back, when dining with a friend. From this time forward the history is—daily attacks of pain in abscess, and, as will be seen from the chart, some hectic. On the 20th the abscess was opened in the usual way described in these papers, giving exit to about three ounces of laudable pus, with a quantity of blood of a dark colour. It was dressed in the usual manner, the aperture kept open with a strip of carbolised lint and antiseptic dressing used. During the 22nd the dressing, which had been put on at the morning visit, became deranged, and a medical officer on duty dressed the wound. This gentleman had been all the morning engaged in a post-mortem examination. The next day the edges of the wound had a distinct blush, and the parts looked angry. This gradually disappeared, and he did fairly well, but the abscess continued to discharge very freely, and as the weather was almost insufferably hot, it was thought he would do better if sent away to sea. The following are the two last entries in the hospital case-book:—Aug. 5th: Temperature yesterday evening and this morning normal; pulse 92, full; slept well after the night draught; tongue slightly furred towards the centre; appetite good; bowels moved once in last twenty-four hours; stools said to be scanty and watery; abscess doing well. To continue treatment and diet.—Aug. 6th: Had a sleeping draught last night; tongue slightly furred; appetite good; bowels moved once during the night. Temperature yesterday evening and this morning normal. Continue treatment.

Aug. 7th.—Embarked for England eighteen days after the operation. I saw a letter from the patient, written in Suez, in which he spoke of himself as better, but he reached England only to die a day or two after arriving home. The ship's doctor, from whom I subsequently heard, reports that the discharge became very profuse on board ship, and the patient's own statement that he was better at Suez was not warranted by his condition. I was intensely disappointed in this case, as it seemed a most promising one. I can only imagine, although there was no external or constitutional indications of more than one, it was a case of multiple abscess. It will be seen from his history that he suffered from dysentery immediately before his liver symptoms set in. Inflammation of the liver following dysentery mostly leads to multiple abscess.



CASE 3.—E. F. H——, aged forty-five. Service, twenty years; residence in India, seven years and two months; habits temperate. This patient, a conductor of the Ordnance department, was admitted under Dr. MacNally, the assistant physician, some time in February. The earlier part of the case seems to have been irregularly kept by the clerks, for no previous history or the man's physical state on admission is to be found in the notes furnished me from the hospital.—The first entry is February 2nd, 1880: Patient had a good night, pain over the hepatic region is much less, leg is healing, bowels moved once yesterday. My remembrance of the case, however, is very distinct. I was asked by Dr. MacNally to see the case with him in consultation, and found a weak, sickly man, with a distinct swelling in the hepatic region, and little or no fluctuation. As there was no indication for immediate interference, and the man was in a nervous, depressed state, it was determined to leave the abscess alone, at any rate for the present. Gradually it must have become more active, for on March 3rd, 1880, occurs this entry: Patient was put under chloroform yesterday in the semi-recumbent position, and the most prominent part marked by ink. An incision was made longitudinally about half an inch with a scalpel, after which a second sized trocar and cannula were introduced and the trocar removed; through the cannula flowed two ounces and a half of thick, lumpy, tenacious pus, tinged with blood; after the pus had ceased to flow a narrow strip of boracic lint was introduced through the cannula, which (cannula) was withdrawn. Over the wound boracic lint, four inches by three inches, was placed and Lister's antiseptic dressing put on. The carbolic spray was in play during the whole of the operation. The patient slept well and feels greatly relieved by the operation. Bowels not open since yesterday; appetite good, eats well.

The operation was performed by Dr. MacNally, as were all the subsequent dressings applied under his supervision. The man did well. I will omit the daily entrances, giving only one or two.—March 13th, 1880: Patient passed a very good night; had two motions since last visit; stools well formed. Patient is putting on flesh; takes all his food. Continue treatment; abscess redressed; discharge diminishing. The abscess, however, continued to discharge pretty freely until March 30th: Patient slept freely last night; tongue clean, appetite good; very little discharge now from the abscess. Continue treatment and diet.—April 13th: Patient discharged from hospital, much improved in health and strength. The abscess has closed up, but a slight superficial wound still remains unhealed. He leaves by this evening's train *en route* to England *viâ* Bombay, having obtained two years' furlough. He telegraphed from Bombay to say that he had borne the journey well, and was to embark in a troopship.

Madras.

CASE OF ATTEMPTED PARACENTESIS PERICARDII.

BY JOSEPH W. HUNT, M.D. LOND.,
PHYSICIAN TO THE WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

THE following case presents more than one point of interest, and shows the difficulty there sometimes is in diagnosing between a largely dilated heart and an adherent pericardium. Reported as shortly as possible, it is as follows:—

Henry W——, aged twenty-three, was sent into the hospital on Jan. 30th, 1880, under my care, by my friend Mr. Wells, towards the close of an attack of acute rheumatic fever. He had had a previous attack eleven years before, when his aortic valves had been affected. During the first week of his stay in the hospital his left pleura (which was filled with fluid) was twice aspirated for the relief of distressing palpitations, dyspnœa and orthopnœa, and an attack of acute pleurisy on the right side was cut short by the application of leeches. When admitted he had a loud aortic diastolic murmur and a largely dilated heart, while in addition pericardial friction was audible over the greater portion of the cardiac area, and there were signs of much pericardial effusion. On Feb. 7th, as there were manifest signs of cardiac failure, and he was apparently on the brink of the grave, I determined to aspirate the pericardium. At that time the physical signs were noted as follows. Only slight pulsation over cardiac area; apex-beat weak and diffused about two inches and a half below nipple; intercostal spaces over lower portion of cardiac area obliterated; upper level of cardiac dulness indicated by a line drawn from the top of the sternum to the left nipple; cardiac sounds very weak below, but above midsternum loud and accompanied by a marked systolic and diastolic bruit, not variable and not increased by pressure; only slight epigastric pulsation; jugulars not full; pulse very irregular, weak and compressible, varying from 60 to 70 or 80 per minute. Respiration 50 to 60 per minute. Marked orthopnœa. Thoroughly recognising the fact that the heart was much dilated, and remarking to the pupils present on the possibility of pericardial adhesions complicating the case, I introduced the finest needle into the pericardium through the fourth interspace near the sternum, and pushed it steadily on for more than an inch, its point being directed upwards. As no fluid came, and the violent pulsation of the needle showed that it had entered the heart walls, it was withdrawn, a little blood being found within the point. No bad symptom followed, and it was my intention to repeat the attempt another day, entering the pericardium an interspace or two higher up, but was prevented by the temporary improvement of the patient, and by a considerable fall in the amount of pericardial dulness. He died from cardiac failure on February 14th. The medical treatment adopted consisted, for the most part, in the frequent administration of digitalis, carbonate of ammonia, and stimulants. Occasionally other remedies were prescribed as required.

At the post-mortem examination the heart was found to be enormously enlarged; it reached from the right border of the sternum to the left nipple, and extended to the top of the sternum. Its right border was crossed by the right lung which was emphysematous, and extended over the middle line. The pericardium was adherent throughout. Over the lower portion the adhesions were strong, and evidently dated some time back, but over the upper portion they were slender, and did not closely bind down the pericardium to the heart, while in their meshes there was some amount of fluid, which was evidently undergoing absorption. On removal, the heart, filled with clot, weighed 31 oz.; when emptied of clot, 28 oz. The aortic valves were incompetent. The left ventricle was enormously dilated, and the muscular walls very much thicker than normal; from their paleness and softness they were evidently undergoing degenerative changes. The left auricle was also hypertrophied and dilated, but the right ventricle only to a slight extent. The mitral was thickened, and its chordæ tendineæ thickened and shortened, so that it probably failed to close completely the auriculo-ventricular orifice. The mark of the aspirator-needle could be distinctly seen in the adherent pericardium over the right ventricle, whence its course could be traced for over an inch through the wall of the right ventricle into the very much hypertrophied ventricular septum. It nowhere entered either ventricle. There was no trace of inflammation, or any other morbid changes along the track of the needle.

Remarks.—The diagnosis in this case was no doubt difficult. A large amount of cardiac dilatation and hypertrophy, depending on the old standing aortic disease, was evident, while the presence of pericardial adhesions to some extent was more than probable. On the other hand, the very large area of cardiac dulness, the obliteration of intercostal spaces, the amount of pericardial friction audible on admission, and which was afterwards lost, rendered the presence of a large amount of effusion probable; and no doubt a considerable amount of fluid, which was afterwards absorbed, would have been withdrawn if I had inserted the needle a little higher up, as I fully intended to do if a second aspiration was indicated. It must be remembered that it was impossible to trace any increase of pericardial dulness at the commencement of his stay in the hospital, owing to the left chest being completely filled with pleural effusion, and pleural and pericardial dulness thus running into each other. The physical signs noted above are what were evident after the pleura had been emptied by two aspirations. It is worth remarking the absence of any ill effects following the introduction of the needle for some considerable distance into the heart walls, and I believe that no harm would have followed even if the needle had entered the ventricle, provided it had been immediately withdrawn, before the contraction of the cardiac walls had helped the needle to tear up their substance. This case may be compared with another in which I attempted to aspirate the pericardium in a case of pericardial effusion complicating rheumatic fever. To my surprise only a few drops of fluid were obtained. The patient died of hyperpyrexia, and post-mortem it was found that the pericardium was widely distended with fluid, but that at the one spot where I aspirated there were adhesions between the heart and pericardium, among which the needle had got entangled and blocked. At all other parts the heart was free from adhesions.

Wolverhampton.

ON GENERAL PARALYSIS OF THE INSANE CONSECUTIVE TO LOCOMOTOR ATAXY.

BY W. JULIUS MICKLE, M.D., M.R.C.P.,
MEDICAL SUPERINTENDENT, GROVE HALL ASYLUM, LONDON.

I HAVE elsewhere[1] briefly referred to the subject of general paralysis consecutive to locomotor ataxy.[2] The cases referred to are those in which the symptoms of true general paralysis of the insane follow on those of true locomotor ataxy, and in which the pathological lesions of general paralysis have been supposed to originate in an extension upwards from the lesions of progressive locomotor ataxia. These cases, and others of like pathological import, have been designated as examples of general paralysis by propagation. The cases just mentioned, as other than those beginning with locomotor ataxy, but of like pathological import, are cases in which some cranial nerve or nerves have first suffered disease, the extension of which to the brain has set up some pathological process ending in general paralysis.

Broadly speaking, in general paralysis the rule is that cerebral symptoms precede spinal. Spinal symptoms, indeed, may be absent or slight, and when present, as a rule, they are secondary both in time and in importance. The usual motor spinal symptoms are either ataxiform or paralytic; the ataxiform are those almost invariably found; the paralytic are accessory and inessential, but, especially in their slighter degrees, are very frequent accompaniments of the later stages of general paralysis. Usually the spinal symptoms are of a mixed character, being both ataxic and paretic in nature.

---

[1] General Paralysis of the Insane, 1880, pp. 82, 83, 141.

[2] The *disease*, "progressive locomotor ataxy," is referred to throughout this paper, not the mere *symptom*, the affection of gait.

There are examples of general paralysis, however, in which the spinal symptoms come on simultaneously with the cerebral; there are also cases in which the spinal symptoms distinctly precede the latter. By this last group the observer is brought a step nearer to the subject now in question, for in cases belonging to it we may, in thought, follow a morbid process which originates in the spinal cord and meninges, and subsequently passes upward to the encephalon and its meninges. But in this group are found the ordinary symptoms and lesions, both spinal and cerebral, of general paralysis; here the ataxy differs from the ataxy of tabes dorsalis. Obviously, cases of this group differ from those in which general paralysis is supposed to follow upon a propagation to the brain of disease from the cord in prior locomotor ataxy. This alleged pathology of the cases has not been fully accepted, and in the case to be related the *causal* relationship of locomotor ataxy to general paralysis is defective in proof. Widely differing cases have been placed on record to exemplify the relationships and co-existence of locomotor ataxy and general paralysis. In some of these it is difficult to be certain, from the description, whether or not true general paralysis, or, again, true locomotor ataxy, was present; in some, either the former or the latter was certainly absent; and in some others, where both seem to have existed, their order of priority is by no means clear; while, again, in some the symptoms of general paralysis and of locomotor ataxy seem to have both appeared and continued simultaneously. Thus, the subject has been obscured by the introduction of cases that will not bear the special interpretation put upon them; and this has partly been due to the formerly imperfect recognition of the ataxiform character of the chief motor affection in general paralysis, the minds of observers having been prejudiced by the word paralysis, as applied to this disease, and by the undoubted paretic and paralytic conditions so often observed therein. Hence, patients in whom the ataxy of general paralysis has been unusually pronounced may readily, but erroneously, have been supposed subject to locomotor ataxy.

There is a slight want of clearness in Voisin's description of the pathogeny and relations of the spinal lesions in general paralysis. Yet it may be gathered that he regards the cases in which the spinal disorders antedate the encephalic as capable of being placed in three groups; in the first of which the spinal and encephalic lesions occur successively but without any relation between them of causality or continuity, similar causes producing first a myelitis and later on the cerebral lesions of general paresis; while in the second group the spinal affection is supposed to cause the encephalic lesion in a reflex manner, primarily affecting the cerebral circulation, the influence of the spinal cord upon vaso-motor phenomena being acknowledged; and, finally, in the third group there is a direct extension of disease to the brain from the pre-existing disease of the cord—the very sort of case we have been speaking of above.

In speaking of general paralysis by propagation—i.e., of general paralysis from extension to the brain of pre-existing disease from other parts of the nervous system—attention will here be confined to the cases in which the antecedent affection has been progressive locomotor ataxy, or grey degeneration of the posterior spinal columns.

I will refer briefly to some of the few cases, supposed of this kind, and already on record. Horn long ago described a case of locomotor ataxy, of nine years' standing, in which general paralysis of the ordinary type supervened. H. Hoffmann placed a doubtful similar instance on record. Baillarger described five cases stated to present the clinical features of both locomotor ataxy and general paralysis; but in one only of these does it seem that general paralysis may have succeeded to undoubted locomotor ataxy. Yet the history is most imperfect, and the sequence of events conjectural. In three others the grandiose mania, and other symptoms of general paralysis, supervened in the first period of locomotor ataxy—that, namely, in which affections of optic and ocular nerves and lightning pains appear, and which, as described by Duchenne more than twenty years ago, precedes the ataxy of the limbs in a typical case, the ataxy of locomotion only appearing in the second stage.

In these three cases it is by no means clear, therefore, that general paralysis may not have existed as early as, or earlier than, the locomotor ataxy, for general paralysis usually exists for some time before distinct exalted delusions are evinced, and therefore in these examples may easily have existed prior to the incipient locomotor ataxy. In the remaining case the mental symptoms and dysphasia of general paralysis distinctly preceded locomotor ataxy by a year. Then, again, in two of these cases it is said that the locomotor ataxy was arrested when general paralysis supervened, and in one, as also in another quoted, the general paralysis underwent recovery, while the locomotor ataxy grew worse. Clearly these cases are dissimilar from those in which there was actual coexistence of the two diseases. Especially is a transitory epiphenomenal appearance of general paralysis in the course of another affection an explanation one cannot accept, and the symptoms should receive some other name. Illustrations of a like kind occur in certain cases recorded by Mr. Plaxton and Dr. Nicol. Teissier's case is inconclusive. The cases mentioned by Topinard, of mental symptoms arising in locomotor ataxy, do not appear to have been instances of general paralysis. Westphal found locomotor ataxy sometimes followed in the later stages of its course by mental disease. The latter, in the character of the mental derangement, in the accompanying paralytic symptoms and emaciation, and in the intercurrent apoplectiform and epileptiform seizures, bore a certain similarity to general paralysis. If standing or walking the patients staggered and fell when the eyes were closed. Vesical failure and the motor disorder in the limbs long preceded the mental symptoms. In these cases of grey degeneration of the posterior columns of the cord, although mental symptoms supervened, it can scarcely be said that there was true general paralysis. The patients were free from impairment of articulation, and at the necropsies no cerebro-meningeal adhesion was found, the deviations from the healthy appearances being that there was some increase of ventricular fluid, and sometimes pia-matral œdema, or softening of the central parts of the cerebrum and paleness of its grey substance. Ph. Rey described three cases of supposed locomotor ataxy with consecutive general paralysis. Motet recorded a similar case, and Falret and Dally a doubtful one, as also Magnan. Foville placed four cases on record as being examples of true locomotor ataxy followed by true general paralysis, after periods varying from two months to six and a half years. One case came under notice too late for recognition of the particular affection of gait present, but it is said that the necropsy revealed sclerosis of the posterior columns of the cord, as well as the ordinary lesions of general paralysis. In another case the patient was demented. In a third exaltation supervened on the mental weakness, and in the fourth an outburst of expansive ambitious erotic mania beset the course of a gradual intellectual enfeeblement. Two of these had amaurosis and one amblyopia, the frequent accessories of locomotor ataxy, and especially in its first stage.

But there are cases in which general paralysis is preceded for some time by an amaurosis unconnected with locomotor ataxy. Three cases of amaurosis preceding general paralysis are vouched for by Mobèche, and examples of a like sequence have been recorded by Lélut, Lasègue, Parchappe, Calmeil, and others. Two such Foville adds to his four cases of locomotor ataxy, making six, and for a seventh takes a case in which was prior paralysis of the third cranial nerve. Falret and Billod also recorded a case of similar antecedent paralysis of the third cranial nerve, while Esquirol speaks of precursory strabismus, and Baillarger of the same with or without ptosis.

(To be concluded.)

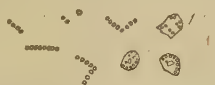
Cambridge: Downing College.—At the College Examination in Natural Science, to be held in June, 1881, in addition to the ordinary Foundation Scholarships, open exclusively to members of the College, one Foundation Scholarship of the annual value of £80 will be thrown open to all members of the University who have not kept more than six terms. The subjects of this examination will be, chemistry (theoretical and practical); physics (heat, electricity, and magnetism); comparative anatomy, physiology, and botany. The Examination for Minor Scholarships, which are open to all persons who have not entered at any College in the University, or who have not resided one entire term in any such College, will be held in Downing College, on Tuesday the 31st of May next and three following days.

ON THE
CONTAGIUM OF IMPETIGO CONTAGIOSA.

BY H. RADCLIFFE CROCKER, M.D.

THOUGH not altogether unknown, this disease did not meet with general recognition and attention until after the publication of Dr. Tilbury Fox's article upon it in the *British Medical Journal* in 1864. Inquiry was naturally directed to the cause of its being contagious. In this country Mr. Hutchinson, in the Pathological Transactions, vol. vi., figures a fungus found in the crusts of two cases only out of many examined, and confesses that therefore the fungus is not an essential part of the disease. Kaposi and Geber have also found a fructifying fungus in the crusts. Geber, however, regards it as accidental. Piffard, in the *New York Medical Journal* for June, 1872, as quoted by Duhring, describes a vegetable organism of various shapes and sizes, mostly extremely minute, circular, oval, biscuit-shaped, and rod-like structures; no mycelium or spores. Occasionally he saw the same fungus as Kaposi. All these organisms were found in the crusts only, and are naturally open to the objections that, besides not being constantly found, they were present in the parts exposed to the air, and were therefore probably deposited from without. Dr. Tilbury Fox searched repeatedly in the fluid, but found no fungus.

So far, therefore, the fungus theory appears to have broken down; but the facts daily accumulating in favour of contagia being particulate led me to investigate the subject anew, and feeling that it was useless to examine the crusts, I selected cases in which the vesicles or pustules were still unruptured, thrust in a capillary tube, and then immediately sealed up the fluid withdrawn. The clear fluid was first examined with a power magnifying 550 diameters, and floating free in the fluid chains of micrococci were found; these were mostly in lines of four, but some longer chains were found and some pairs. The number was not very great, and on account of their minute size could be easily overlooked. In the pustular fluid the organisms were not certainly recognisable, owing to the large number of corpuscles and epithelium present with their débris. On staining the fluid with methanilin-violet the difficulty was removed, and micrococci in far larger numbers than in the clear fluid were to be seen; some were free in chains of two to eight or more, either in curved or straight lines; others were attached to the epithelium, but, so far as was observed, not to the pus-corpuscles. These latter stained much more readily than the small epithelial scales, and the micrococci stained deeply, and were therefore readily discerned in or on the epithelium. They were situated for the most part at the borders of the epithelium, though sometimes they were in the centre as well. Besides the chains some larger circular organisms were seen, but separate and comparatively few in number. No bacteria were observed. The micrococci could be seen with a power of 350 diameters, but of course a higher power was advantageous. Are these organisms the source of the contagion? It must be admitted that there is not absolute proof of it, and nothing but their successful cultivation, and inoculation with the cultivated fluid, would give a complete answer; but that their presence is not merely accidental is evidenced by their uniformity, so far as I have investigated, in unruptured vesicles and pustules, and in greater number in the pustules; while that they are intimately connected with the contagious property of the fluid, either as the contagium itself or as carriers, is rendered highly probable by the facts accumulating almost daily, connecting similar organisms with other contagia. Further investigation can alone decide this; but at present I merely wish to place the facts already ascertained upon record.



Micrococci of impetigo contagiosa free in the fluid from a vesicle or pustule, and on the detached epithelial scales.

Welbeck-street, W.

ON THE USE OF THE SOLID RUBBER BANDAGE IN THE AFTER-TREATMENT OF SOME FORMS OF DISLOCATION AND ITS ATTENDANT RIGIDITY.

BY H. J. FORSTER, L.R.C.S.I.

PERHAPS in the whole category of complaints which the general practitioner has to treat there are none more productive of an annoyance to himself and anxiety to his patient than the partial anchylosis and œdema which are consequent more or less generally on all forms of dislocation. These disagreeable after-results might easily be avoided, or at all events reduced to a minimum, in suitable cases, if the medical attendant, after the proper manipulation of the joint and a few days' rest, were to apply a suitable elastic support and enjoin the patient to move about short of fatiguing the injured part. In the subjoined cases in illustration of the above remarks, no originality of treatment is claimed save in the material used, the advantages of which over the ordinary bandage I shall endeavour to prove.

In July last I was consulted by a patient who informed me that during the previously severe winter she had slipped and broken the small bone of her leg, as well as putting her ankle out. So the bone-setter under whose care she had been during the interval had told her. On examining the injured parts there were found considerable œdema and partial anchylosis. She also stated that her leg had been fomented and poulticed for some months, and as she had not regained her usual strength under this treatment, splints were applied from knee to ankle, and strict rest enjoined. On being requested by me to get up from the sofa on which she was lying and to move about, or even stand on her foot, she evidenced such symptoms of fear and dread of pain that I considered it useless to persist further. I consequently applied a rubber bandage as tightly as could be borne over the ankle and lower part of the leg, with the injunction it was to be removed at bedtime and reapplied in the morning. This treatment was persevered in for the next four days, when on again calling I found she could walk about fairly well, and that the œdema had almost entirely disappeared. After the expiration of a month, during which time she wore the bandage daily, she said she felt about as well as ever, and could walk any reasonable distance without help.

Another case, that of a man over whose ankle an empty cart had passed, after being under the care of an irregular practitioner for nearly three months, found himself at the end of that time with a more or less stiff joint. In his case, after the fibrous adhesions had been broken up in the manner so well described by Dr. W. Hood in the pages of THE LANCET, the bandage was applied and he was ordered to get about. In a short time the result was as good as could be desired.

Three cases of partial dislocation of the cartilage of the knee-joint, after being reduced, were treated in the same manner, and gave no further trouble, not even necessitating the usual preliminary few days' rest.

Four other cases of severe sprains, two of the wrist and two of the ankle, were also successfully treated in the same fashion.

The advantages which I have found to accrue from the use of the solid rubber bandage over the ordinary calico one are the continuous elastic resistance offered by it, and the consequent absorption both of fibrous, callous, and serous effusion, as well as a greater feeling of support, enabling the patient to move about with more confidence. In these points the calico bandage must be deficient for obvious reasons. Also, in the neighbourhood of the knee-joint, there is not merely greater adaptability in the bandage *per se* over even the ordinary elastic knee-cap, but by its greater density and elastic pressure it serves to keep *in situ* what a substance more or less wanting in these two properties can hardly be expected to fulfil. The one drawback experienced in the continuous use of the rubber bandage is the production of minute vesicles, which may become troublesome; however, this inconvenience may be avoided by punching several small holes in the material at suitable intervals.

Market Deeping.

A FEW NOTES ON A SUCCESSFUL CASE OF LARYNGO-TRACHEOTOMY IN ACUTE LARYNGITIS.

BY R. H. A. HUNTER, M.R.C.S.

ON the night of May 10th, 1879, I was asked to see E. P——, a stout, healthy-looking female child, aged nine years, said to be suffering from severe cold and sore-throat. On visiting the house I found the patient in bed, feverish, and complaining of slight pain in the region of the pomum Adami. There was difficulty of breathing, and a croupy cough. The throat and lungs were healthy. I ordered the air of the room to be kept warm and moist, and poppy-head fomentations to be applied to the throat. I prescribed a strong calomel and jalap powder, and a febrifuge mixture containing bromide of potassium, with light diet. On the following morning, finding the symptoms aggravated, I prescribed a second calomel and jalap powder, which, like the first, acted freely.

May 11th.—The cough, difficulty of breathing, and fever had increased. In the evening the patient became delirious. Respiration was greatly obstructed, lungs congested, cough smothered, and higher temperature. During the latter part of the day the child had suffered from frequent severe attacks of spasm of the glottis, requiring two attendants to prevent her jumping out of bed.

I now decided to perform laryngo-tracheotomy. With the assistance of a neighbouring practitioner, the child was placed on a table, and, chloroform being administered, the operation was completed in the usual way. On recovering from the chloroform, and being replaced in bed, the child breathed freely and easily.

13th.—The patient appeared much better. She had slept well, and the delirium had passed off. Ordered bromide of potassium mixture to be continued; diet, milk and beef-tea. During the day she continued to improve. The cough and respiration were easier, and the temperature lower; collection of mucus troublesome.

On the 14th and 15th the child continued to improve, and on the 16th she seemed so much better that I removed the tube, and allowed respiration to be carried on through the opening remaining in the windpipe. Ordered the wound to be frequently sponged with warm water containing a little Condy's fluid. Full diet.

On June 2nd the wound had completely closed; the child was out of bed, and able to eat, drink, and talk well.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

CASES OF AMYOTROPHIC LATERAL SCLEROSIS.

(Under the care of Dr. FERRIER.)

UNDER the title "Sclérose latéral amyotrophique," Charcot has classified an assemblage of symptoms depending on symmetrical sclerosis of the lateral columns, and atrophy of certain motor nuclei of the medulla oblongata and anterior horns of the spinal cord. The symptoms usually commence in the upper extremities with paresis followed by rigidity, and ultimately by muscular atrophy more or less extensive. The lower extremities are also affected by paresis or paralysis and rigidity, but muscular atrophy is absent or slight. The last stage is the occurrence of bulbar paralysis.

The cases of this affection already on record are not so numerous as to render others at all superfluous, and more particularly as Charcot's nosography has been disputed by some. Leyden holds that there is nothing to warrant the differentiation of a separate class from those of the typical bulbar paralysis of Duchenne, with more or less extensive muscular atrophy elsewhere. In particular, he denies the fact of antecedent paresis or paralysis, and the occurrence of contracture or rigidity of the limbs. The following two cases confirm in all main points the association of symptoms described by Charcot. They do not, however, conform to the usual march of the disease. In both the bulbar symptoms were the first to attract attention, if not actually the first indications of the disease. The course of the symptoms is not, however, regarded by Charcot as an essential feature, and he refers to two cases in which also the disease commenced with bulbar symptoms.

CASE 1.—A. W——, aged thirty-eight, admitted on Oct. 15th, 1880. The patient had enjoyed good health, and never had specific disease. The present illness came on a year and a half ago. The morning after a long railway journey he found that his speech was affected so that he could not speak plainly. He also noticed some difficulty in swallowing liquids. He was treated at this time for relaxed throat. He thinks also that some mention was made of a polypus in the nose, owing doubtless to the nasal tone of his voice. Six months after the occurrence of the throat symptoms, about Nov. 1879, he observed that he had difficulty in turning a key in the lock, and about the same time that he had difficulty in walking. Dr. Robertson Lewis of Bristol, who had seen him in February, 1880, stated in a note that at that time there was very perceptible weakness in the arms. He had difficulty in writing, he could not raise his arms, and complained of pains in his shoulders. The legs were specially observed to be weak a month later. The arms and legs gradually became more weak and stiff. Decided wasting of the ball of the thumbs was observed in May.

Present state.—The patient is helpless, and unable to stand or walk, being obliged to lie in bed or sit propped up in a chair.—*Face:* The facial furrows are distinct, but not accentuated. He can purse up his lips somewhat, but cannot whistle or blow. He can inflate his cheeks if the nostrils are compressed, but cannot purse his lips sufficiently close to whistle. His voice is very nasal, there being a nasal souffle with all explosives. He pronounces "grub" as "ngrum," &c. The soft palate does not rise during inspiration or phonation, but contracts actively on being touched. The tongue is protruded straight, but is very tremulous and corrugated from muscular wasting. He keeps his head generally bent on the chest, but he can turn it to the right or left freely, though he cannot turn it back so far as normal. There is no marked rigidity in the muscles of the neck.

Upper extremities.—The upper arms are kept usually closely approximated to the chest, and the hands resting on the abdomen or thighs in the pronated position. He cannot raise the upper arms from the chest. Can only shrug the right shoulder a little; the left more readily. Can bring the left arm across the chest, and touch the right ear with the left hand, but cannot make a similar movement with the right. The movements are very slow and feeble, and accompanied with pain. Cannot cross the hands behind the back. Passive movements of the shoulder-joint indicate considerable resistance and rigidity, and cause great pain. The deltoids are much wasted. The trapezii are the seat of fibrillar tremors. The arms generally are emaciated, and fibrillar tremors are more or less general in the muscles. Can flex and extend the elbow joints. Can pronate and supinate the left hand, but cannot supinate the right. Can extend the left wrist feebly, and to the radial side only, but not the right. The muscles of the thenar and hypothenar eminences and the interossei are much wasted. Abduction and adduction of the fingers and apposition of the thumb impossible. The first metacarpal bone of the left hand is on a level with the second—the monkey thumb, and the basal phalanx of the forefinger hyper-extended. The wasted muscles are the seat of fibrillary tremors and subsultus. There is no reaction of degeneration to galvanic exploration, and the muscles react to the faradaic current, except the left thenar muscles.

Lower extremities.—There is no perceptible atrophy in any of the muscles of the lower extremities. There is marked rigidity and resistance to every movement, flexion, extension, and particularly to separation of the knees, which spring together forcibly when released, owing to the excessive contraction of the adductors. The feet bend to equino-varus position, and the proximal phalanges of the toes are hyperextended. When the patient is supported he can scarcely move the limbs. Though he can feebly flex or extend the leg it is with effort, and he feels as if his feet were glued to the ground. The patellar tendon reflex is greatly exaggerated, and ankle clonus readily excited on both sides. The plantar cutaneous reflex is distinct on both sides. The cremasteric reflex is obtainable on both sides. The abdominal and epigastric reflexes are obtained with difficulty. Sensation, general and special, is unimpaired throughout; and the functions of the bladder and rectum in normal condition. The ophthalmoscopic appearances are entirely negative.

The condition of the patient did not alter appreciably during the whole period of his stay in the hospital. He was treated mainly with the constant current daily, and for a month before his departure with extract of Calabar bean in gradually increasing doses, from a quarter to one grain and a half three times a day. The rigidity of the lower extremities diminished somewhat under the physostigma treatment, but the patient said he felt more feeble. No real improvement was effected, nor indeed could it be looked for.

CASE 2.—R. M——, aged forty-four, a ship steward. Five years ago he fell overboard, and remained in the cold water for about a quarter of an hour, to which immersion he attributes his illness, which began some months afterwards with difficulty of speech. His voice had a nasal tone, and he had difficulty in swallowing. Three or four months after this he experienced weakness and tremulousness of the legs, which caused difficulty in maintaining his footing on deck, and going up or down stairs. He continued at his occupation on board ship for two years after the onset of the symptoms, but he was then obliged to relinquish it. He was admitted into St. Bartholomew's Hospital in April, 1878, and was under the care of Dr. Church for two months. Dr. Ormerod published some notes of his case in the St. Bartholomew's Hospital Reports, vol. xiv. At that time the patient had nasal speech, without evident paralysis of his soft palate, irritability and feebleness of his muscles, and tremulousness and weakness of his legs, particularly the right, which he dragged somewhat. In October, 1878, he was admitted into the Regent's-park Hospital for Epilepsy and Paralysis, and was treated by M. de Watteville. At this time the symptoms, according to the notes supplied me by M. de Watteville, were great weakness and rigidity of the legs, particularly the right, with exaggerated patellar reflexes. The arms were also weak, and the tendon reflexes exaggerated. Speech was markedly nasal, and there was considerable difficulty in swallowing solids. The soft palate rose only slightly during inspiration or phonation. There was also some diminution of sensibility of the right side at this time. (See *Brain*, vol. ii., pp. 179–180.) Under galvanic treatment of the upper and lower part of the spinal cord, and local treatment of the pharynx and larynx, there was a marked improvement, in the bulbar symptoms especially. But, after a fall in the month of November, the weakness of the limbs increased, though the bulbar symptoms remained in abeyance. After this period the patient came under my care both at Regent's-park Hospital and subsequently at King's College Hospital, and he has been under my observation at intervals up to his admission into the National Hospital for the Paralysed and Epileptic on Jan. 28th, 1881.

Present state.—Face: The muscles of expression act normally on both sides. The tongue is protruded straight, somewhat tremulous and wrinkled. The masseters, pterygoids, and buccinators act energetically. The soft palate rises only very slightly during a deep inspiration or on phonation, but contracts readily to touch. He cannot purse up his lips so as to whistle. Deglutition is good. Speech is very nasal, and all explosives have a nasal souffle. They are pronounced quite distinctly when the nostrils are compressed. There is no observable rigidity in the muscles of the neck.

Upper extremities.—All the movements of the arms are retained, but are feeble, and the muscles are soft and flabby. There is some difficulty in raising the arms well away from the sides, owing to stiffness about the shoulders, especially the pectoral muscles, and on the right side more particularly. The interossei and muscles of the thenar and hypothenar eminences are soft, considerably wasted, feeble and tremulous. Grasp of the right hand, 45 lb.; left 40 lb. All the muscles of the arms respond with abnormal readiness to percussion, and the wrist, olecranon, and acromial tap excite active contraction. The faradaic excitability of the muscles is retained, and within normal limits. That of the interossei and muscles of the ball of the thumbs is slightly diminished.

Lower extremities.—The patient walks with great difficulty. The legs tend to adduct, and the feet to assume the equino-varus position. The feet seem to stick to the ground, and progression requires hitching up the shoulder to allow the feet to be raised and advanced, rubbing on the ground. This is more marked in the right leg than the left. When lying in bed he can lift the heel, and flex and extend either knee with considerable force. Abduction of the legs is difficult, and also dorsal flexion of the feet. Occasionally severe spasms come on in the adductors and extensors of the leg, and the feet assume the equino-varus position with hyperextension of the basal phalanges. The contraction of the adductors is sometimes so great as to resist all attempts to separate the legs, and to require the interposition of a pillow between the knees to obviate the painful pressure. The patient complains of more or less constant pain in the region of the adductors, shooting upwards into the pelvis. He also complains of pains in the hips. The patellar reflex is excessive on both sides. The slightest tap excites almost tetanic extension of the leg. Ankle clonus is readily obtained on both sides. Clonus of the hamstrings is also readily produced when he assumes the position of sitting down in a chair. The plantar reflexes are absent, as also the abdominal and epigastric. Tactile sensibility is acute in the legs, and also generally. There is no appreciable difference between the two sides. The special senses are normal. The functions of the bladder are fairly normal, except that it must be emptied immediately on desire, otherwise there is difficulty in retention.

The patient was discharged on April 30th, considerably improved in general health, and with some diminution of the rigidity and pain in the lower extremities. Various methods of treatment, electrical and medicinal, were employed, but large doses of the combined iodide and bromide of potassium and rest in bed seemed to prove most beneficial.

Remarks.—The symptoms in both these cases agree in the essential features of the association of paresis, rigidity, and muscular atrophy, bulbar and spinal, with the cases of amyotrophic lateral sclerosis described by Charcot, and shown by him and by Gombault, Debove, &c., to be associated with sclerosis of the lateral columns, and atrophy of the motor cells of the bulb and spinal cord. The exact order in which these regions are implicated does not materially affect the general result. The assemblage of symptoms differs sufficiently from simple bulbar paralysis, or bulbar paralysis with more or less extensive muscular atrophy, in the well marked paresis and rigidity of the limbs preceding the atrophic wasting; and from ordinary secondary descending sclerosis, or primary lateral sclerosis, in the muscular atrophy, as to justify their being classed together as a distinct systematic group.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

THREE CASES OF POISONING BY THE ŒNANTHE CROCATA OR HEMLOCK WATER-DROPWORT, ONE FATAL.

WE are indebted to Dr. H. A. Bampton for the following notes of these cases.

The recorded cases of poisoning by the Œnanthe crocata are so few in number, that the following may be of professional interest, the more especially as in this part of the country poisoning by this indigenous member of the Umbelliferæ family is by no means rare amongst watering parties of foreign seamen. In 1869, at Falmouth, a party of twenty-seven sailors ate of the herb; four of them died. Last year the crew of an Italian barque partook of the same herb, mistaking it for wild celery; five of them died. A boat's crew of H.M.S. *Wellington*, while on shore at Campbeltown some years since, dug up a quantity and partook of some. Eight became very ill; two of them died.

On March 12th, about 2 P.M., three sailors from the Greek ship *Orpheus* landed at Jenny Cliff to collect water at a spring which rises hard by the shore. Having completed their work, two of them, George and Nicholls, dug up a plant which they mistook for the wild celery which grows in great abundance in watery districts in Greece, and is in great favour amongst the seafaring population as an article of diet. George ate about a root and a half, the root being about the size of an average parsnip, which it resembles in appearance; Nicholls ate but an inch and a half of the root; and Andrews, a seaman from the Greek ship *Chios*, who was on a similar mission, the leaves and stalks of two or three plants. Andrews gave the following account of himself. He said the plant tasted as sweet as sugar. When he got on board, about three-quarters of an hour afterwards, his nose began to burn from eructations and constant spitting of thick stuff; his limbs felt weak and the muscles contracted, and he had tremors in the limbs and joints. He thought he had overworked himself, and he asked the captain for a shilling to go ashore to buy some rum, which he did, and soon felt all right after drinking it. He seems to have taken about a quarter of a pint of rum. He experienced no other symptoms nor discomfort. But Michael Nicholls, who ate more than one inch of the root, was not so fortunate. He states that the root tasted very sweet, but did not burn. He pulled off with others to the ship and emptied some casks, which occupied about three-quarters of an hour. He felt giddy and cold, had tremors in the limbs, could not see, but could hear. He was unconscious for half an hour, and on becoming conscious he had pain in the head, as if it were being cut off, and he had twisting, grinding pain in the stomach; thick phlegm collected at the back of the throat, and he was not sick till some melted butter was given him at about 4 P.M. He felt very weak and cold, with pain all over body, and could not walk without assistance. An emetic of sulphate of zinc was given to him by Mr. Fox, surgeon, about 6 P.M., after which he vomited, and was brought to the hospital a little after 7 P.M., nearly five hours after taking the poison. On admission, the patient was apparently conscious, though he stated afterwards he did not remember being carried to the hospital, though he remembered being put to bed by the nurses. From that time till noon the next day he did not remember anything further. His pupils were normal, the conjunctivæ highly injected. He moaned with constant expectoration, the pulse was fair, but the extremities were cold. Patient was placed in bed, and sinapisms were applied to the calves of the legs and thorax, and hot bottles to the feet, while hot brandy-and-water was administered internally; he would not take much, but crouched under the clothes and expectorated freely. Dr. Prance, one of the physicians to the hospital, saw him at this juncture.

On the following day he was drowsy and had a fair pulse. The urine contained abundant lithates. Patient complained of pain in the eyeballs, where there was increased tension; he said people in the ward looked very small till noon. The corneæ were dull and the conjunctivæ still injected. No pain anywhere else. As bowels were confined castor oil was ordered, which brought away a firm greenish-coloured stool.

On March 14th he expectorated viscid greenish-brown sputa. Roughened expiration; had a slight attack of epistaxis.

15th.—Rusty viscid sputa, with sibilant râles; felt quite well; no cough.

16th.—Discharged well.

George J——, whose case terminated fatally, ate a root and a half, and was able to perform the duties of rowing back to the ship, and unloading the boat, up to nearly an hour after having eaten the poison. He was walking across the deck when he suddenly fell down, as if shot, on the back of his head, inflicting a scalp wound. He cried out, "My God, I am done for!" vomited up some green stuff, and got green in the face, with eyeballs turned up. He foamed at the mouth with a thick mucus, which he was unable to bring up because he was apparently unconscious. He could not swallow. He was turned on his face by the crew, to endeavour to get rid of the mucus. The hands were clenched at times, and he had spasmodic contractions of the muscles of the legs and face. About five hours after the fatal meal he was carried to the hospital in a moribund condition. At the time of admission he was unconscious; the pupils were widely dilated; the pulse was perceptible, but slowed; respiration was impeded by a quantity of thick mucus, which filled his mouth and throat, and covered his beard. The extremities were cold. As respiration failed artificial respiration was tried, but with no avail; the patient died about ten minutes after admission. The muscular system was relaxed, with occasional spasmodic twitches.

Necropsy, forty-three hours after death.—Body well developed and muscular, age about thirty-five years. Post-mortem rigidity strongly marked; slight purple staining at back of neck and shoulders. The abdomen contained a small amount of gas. Diaphragm arched. The stomach was distended and of a bright pink colour, from injection of vessels. The transverse colon was contracted, and contained a small quantity of soft fæces; no trace of vegetable fibre could be detected even with a glass of high power. The stomach contained a quarter of a pint of grumous sour-smelling material, the colour of treacle. No trace of root could be found; there were several scattered inflammatory patches, and some brown discolourations where the mucous membrane was thin, at the greater curvature. Gall-bladder empty. On section of liver a large escape of dark-coloured blood. Spleen and kidneys normal. Bladder contracted, containing an ounce of urine. Descending colon and rectum distended, contained no fæces. The right ventricle of the heart contained a small quantity of fluid dark-coloured blood; the left a less quantity, thicker and darker. Muscular walls very relaxed and flaccid; muscular tissue soft and bloody. There were pleural adhesions. The lungs were congested and full of blood of a dark colour, and the bronchial tubes were full of mucus, as also trachea and mouth. No hæmorrhages from mouth, nose, or ears; no bruising of bone at seat of scalp wound. The dura mater was non-adherent at surface of the brain. The venous sinuses were distended, meningeal vessels injected, cerebral vessels strongly injected. Pia mater bled easily on section. There was a small effusion of lymph over surface of brain. The cerebellum was very soft, with small clots of dark blood between convolutions posteriorly. Small quantity of fluid in ventricles. The bright red vascularity of the surface of this brain contrasted strongly with the almost white brain from a subject who had died from scurvy, a necropsy of which was made on that day.

Remarks by Dr. BAMPTON.—The literature on this herb-poisoning is very scanty. Caspar gives an account, with an uncertain sound, of a supposed case. No symptoms were known. Post-mortem signs coincide with the above. Von Boeck gives some of the symptoms, but no post-mortem signs. Taylor mentions several cases, and gives the best account I have yet seen. The symptoms from the foregoing cases seem to be—muscular weakness, when small quantities are taken; complete paralysis in large; gastric irritation, visual disturbance, giddiness, excessive secretion of bronchial mucus—a marked symptom; more or less loss of consciousness, loss of temperature, enfeebled respiration. Cardiac action slowed; continued up to time that respiration ceased. Dilatation of the pupil in the fatal case, the third nerve participating in the general motor paralysis; loss of power in deglutition. The symptoms and post-mortem signs of poisoning from the Conium maculatum, Œnanthe crocata, Cicuta virosa, and Æthusa cynapium do not vary much. Motor paralysis is a prominent symptom. The post-mortem signs are: fluidity of the blood, hyperæmia of the brain, venous hyperæmia of the lungs, and the signs of death from asphyxia (Von Boeck). In the stomach extravasations and hyperæmic patches. The treatment indicated seems to be the early use of the stomach-pump, or of emetics; artificial respiration to be persevered with to the last; the administration of a strong infusion of tea to serve as a respiratory and general nerve stimulant; the tannin might also act as a chemical antidote by forming a precipitate; turpentine enemata and warmth. The explanation of the clinical experience, that conium is useful in allaying bronchial irritation, may be found in an analogous action to the Œnanthe crocata in promoting the secretion of mucus, thus covering the irritable surface and protecting it from cold winds in the upper portion of the respiratory tract. An anonymous correspondent in the *Standard* has taken upon himself to write that these cases of herb-poisoning must have been from the plant Sium angustifolium, and not the Œnanthe crocata, as stated. Now, the Sium angustifolium, or water-parsnip may be mistaken for watercress, but not for celery; whilst, on the other hand, the stem of the Œnanthe crocata may easily be mistaken for celery. The stem of a specimen procured by one of the sailors who recovered, from the same watering-place, was very like, as it had been bleached from being underground; the root is composed of a number of tubercles not unlike small parsnips, sweet to the taste. The most active part of the plant is the root—in its poisonous action especially—at this time of the year. It grows in great abundance in this neighbourhood. Browsing cattle are sometimes poisoned by it. It is unmistakably the Œnanthe crocata, and is well known to local botanists; and I doubt whether the anonymous correspondent of the

Standard could mistake it for the Sium angustifolium if he had ever seen it or compared the two. A Mr. Loverdo very opportunely suggests, in a letter to the *Standard* and other papers, that the captains of foreign ships should be warned of the various poisonous herbs that are indigenous to the localities about our seaports.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Intestinal Obstruction.—Tumour of Brain.—Calcareous Plates in Heart.—Pylephlebitis.—Ulcer of the Stomach.—Filaria Sanguinis Hominis.—Keloid of Pinna.—Pulmonary Aneurism.—Cerebral Aneurism.—Syphilitic Disease of Cerebral Vessels.—Encapsulation of an Ivory Peg in Bone.—Subastragaloid Dislocation of Foot.—Dislocation of Astragalus.—Genu Valgum.—Sarcoma of Femur.—Vesical Calculi.—Malformation of Heart.—Valvular Disease of Heart.—Cranio-tabes.

THE last ordinary meeting of the present session of the Pathological Society was held on Tuesday, May 17th, S. Wilks, M.D., in the chair. Two reports of the Morbid Growths Committee were presented, and although the list of agenda was a long one, the specimens were shown with such expedition that the meeting adjourned shortly before the usual hour.

Mr. BUTLIN read a report of the Morbid Growths Committee on Mr. Moulin's case of Cystic Disease of the Mamma, the conclusion arrived at being that it was an ill-developed carcinoma, the cysts being produced by plugging of the ducts with epithelium and secretion of fluid in the acini.

Dr. PAYNE read the report of Messrs. Beck and Godlee on Mr. Rushton Parker's case of Adeno-fibroma and Carcinoma affecting the same breast, by which Mr. Parker's description was fully confirmed.

Dr. TURNER showed a case of Intestinal Obstruction by a band. The patient, a child, under Dr. Sutton's care, was attacked with pain in the belly, followed next morning with intense pain and violent vomiting with free action of the bowels. When seen three days after the onset of the illness the belly was tympanitic and very distended; no great pain or tenderness. Mr. Rivington operated, and found several congested coils of intestine on the right side of a band which passed from the ileum to the umbilicus; the gut was reduced. The boy died in a few hours. Three bodies, like plum-stones, were found in the strangulated gut. The cord was found to contain a diverticulum of the ileum, and was situated about eighteen inches from the ileo-cæcal valve, the congested coils of intestine commenced just above the band.—Dr. WILKS asked if, at the time of operation, it was evident what the nature of the band was, and whether the surgeon was prepared to cut it through if necessary.—Dr. TURNER was not present, and did not know Mr. Rivington's views.

Dr. N. MOORE showed a Tumour involving the optic tracts, chiasma, and nerves within the skull. In nature it was a glioma. The whole of the rest of the encephalon was quite healthy. The man, aged thirty-four, died in St. Bartholomew's Hospital in January, 1881. He had been ill for ten months, with great thirst, loss of weight, and failing vision, with extreme white atrophy of the left optic disc, and to a less degree of the right. He passed from five to eleven pints of urine a day; no sugar or albumen ever found; sp. gr. 1004 to 1006. He became quite blind, and later on delirious, and then in a condition of stupor; no paralysis. Lancereaux records cases of diabetes insipidus from injury to the anterior part of the skull; this case was of interest in connexion with those cases.—Dr. S. WILKS asked if Dr. N. Moore had formed a theory as to the mode of production of the diabetes.—Dr. BAXTER asked what the condition of the right optic disc was during life, whether there was evidence of neuritis, or whether the atrophy was a primary change.—Dr. N. MOORE said he had quoted Mr. Vernon's opinion, the right disc was at first pale and later distinctly atrophied.—Dr. ORMEROD asked if the quantity of urine at all corresponded to the growth of the tumour.—Dr. N. MOORE replied in the negative.

Dr. BURNET exhibited a Heart with Calcareous Plates, obtained from a woman aged thirty-four. She suffered from ascites and anasarca. Rough rasping was felt over and with apex beat of heart; there was a strange click before running into systolic sound; later on the heart's action was very irregular, and a systolic bruit was observed. At the autopsy, in addition to other changes, four calcareous plates were found: two on the exterior of the ventricles and two on the inside, close to the auricles.—Dr. N. MOORE asked if either of the plates was pericardial, and whether one was connected with the auriculo-ventricular fibro-cartilaginous ring. They were not bony, and not associated with disease of endocardium, and possibly they had a different origin on the two surfaces of the ventricle.—Dr. BURNET thought they were neither pericardial nor connected with the auriculo-ventricular ring.

Dr. GOODHART showed a Microscopical specimen of Local Cirrhosis due to Pylephlebitis. A boy had abscesses and empyema, and lardaceous visceral disease. The portal vein was found completely obliterated with old adherent clot, with purulent matter in its centre. In various parts of the liver there were fibrous puckered scars with a yellow centre. Some of the smaller portal veins contained pus, and one cold abscess was found in the liver. His view was that the pylephlebitis had partly ended in suppuration, and partly in cirrhosis.—Dr. WILKS said the change was analogous to that found in surgical kidney.

Dr. GOODHART also exhibited a case of Ulcer of the Stomach in an infant at birth. The child vomited blood and died; a small perforating ulcer, with a small vessel at the bottom, was found at the extreme cardiac end of the stomach, at the greater curvature. It was in all its characters a miniature of the perforating ulcers of adults. There is only one, doubtful, similar case on record, mentioned by Dr. Wilson Fox.

Dr. THIN showed (for Dr. Manson of Amoy) a small Lymph-scrotum, with part of the female parent filaria sanguinis hominis still *in situ* lying in a dilated lymphatic, the male being, probably, Dr. Manson believed, in some part of the growth. He also showed an Elephantiasis Tumour of the Scrotum, in which the condition had supervened on that of lymph-scrotum. With these he exhibited also for Dr. Manson two Keloid Growths excised from the lobules of the ears of the same woman, growing from the earring punctures, the symmetrical character of the growths producing a peculiar effect, as was well seen from a photograph of the patient which had been sent with the specimens. Dr. Thin had examined part of one of the tumours minutely and had found the usual keloid tissue.—Dr. S. WILKS asked if this was the filaria sanguinis, and whether it was found in the blood.—Dr. THIN said "Yes," and that the filaria in the younger stage was in the blood of one person in ten in Amoy, but much more frequently found at night than during the day.

Dr. S. WEST showed two cases of Pulmonary Aneurism. In both cases the opposite lung was nearly healthy, and in one the disease very localised. In both there was a short history, while the disease must have been of long standing; in one a large laminated clot was found filling up a pulmonary cavity, in the other the lung was almost entirely excavated.—Dr. S. WILKS said that many cases of fatal hæmorrhage from pulmonary aneurism had now been recorded, and he thought all cases of fatal hæmoptysis were due not to destruction of the lung, but to secondary vascular change; and in such cases the disease was chronic and localised, with hardly any hint of phthisis.—Dr. S. WEST said he had always been able to find the cause of fatal pulmonary hæmorrhage.—Dr. S. WEST also showed an aneurism from a woman who had occasional sickness and headache, and who suddenly became unconscious, and died in four hours. Post-mortem, blood was seen covering the base of the brain and reaching into the fourth ventricle, and a small aneurism on the posterior communicating artery was found with an extensive rupture. No other disease. A boy, aged twelve, with adherent pericardium and mitral disease, was seized with sickness, headache, and coma, and died in a few hours. Suffusion of blood over the whole base of the brain was found, and a ruptured aneurism on the middle cerebral artery was discovered, the rupture being into the descending cornu of the lateral ventricle; the blood had reached the surface through the transverse fissure; the artery was very brittle; no evidence of embolism.

Mr. W. ANDERSON exhibited drawings of Syphilitic

Disease of the Cerebral Vessels. The special symptoms in the case were acute tetanus, hyperpyrexia, and coma just before death, and he thought this was an unprecedented occurrence in these cases. The changes found were those described by Heubner, and affected chiefly the intima.—Mr. W. ANDERSON also showed a specimen of Encapsulation of an Ivory Peg after Dieffenbach's operation for false joint. The peg had been retained for nearly four months; it was quite unchanged, apparently owing to its encapsulation.

Mr. H. MORRIS showed three cases—1. Subastragaloid Dislocation outwards of the Foot. Five years ago the man suffered a severe fall, one leg was amputated at the time. The other, much injured, was saved, but has been a constant source of annoyance to him, and he begged for its amputation, and thus the specimen was obtained. Its chief interest lay in the great laceration of all the tendons passing round the ankle. 2. Dislocation of the Astragalus. A woman, aged sixty, met with a fall sixteen years ago. The sole of the foot was turned in, the deformity being exactly like talipes equino varus. The astragalus is dislocated from the os calcis and scaphoid, and is rotated on itself, so that its upper and inner border is under the tibia. 3. Genu Valgum, a dissected specimen, showing an enormous hypertrophy of the inner condyle, and a large supplemental mass of cartilage on outer condyle, with very misshapen patella. Eight years before, the boy, now aged seventeen, met with a severe accident, in which, however, the knee was not injured. After it a lump formed over the lower part of the tibia, and was opened and sinuses developed, which have never healed; the knee swelled and grew big on its inner side. Six years ago he injured his elbow, and there also is a large growth. The fibula could not be traced all down the leg; the leg was amputated, and a fracture of the tibia was then found with a false joint, and the fibula is there in contact with the tibia and helping to support the weight of the body.

Mr. EVE showed a recent specimen of Sarcoma of the Femur. A young woman, aged twenty-five, four months ago had a blow on the right knee, followed by swelling. On admission to St. Bartholomew's the joint was swollen, and the skin red. The limb was amputated, and it was then found that the external condyle of the femur was destroyed by a malignant growth, which had also burst into the joint and infiltrated the synovial membrane. It was interesting as following on an injury and as simulating disease of the knee in its earlier stages. The tumour is a small spindle-celled sarcoma.

Dr. F. TAYLOR showed two Calculi (for Dr. Curran)—one of them of peculiar shape, which was situated partly in the urethra, and had to be pulled back into the bladder before it could be removed. The other, two inches long, was passed spontaneously by a woman in India.

Dr. TIRARD showed a case of Malformation of the Heart from a child five months old. There was no cyanosis during life. Post mortem the following changes were found:—two aortic cusps, four pulmonary cusps, a patent foramen ovale, aperture through the septum ventriculorum, and disease of both mitral and tricuspid valves.

Dr. CARRINGTON showed a specimen of Mitral Tricuspid and Aortic Disease; the Tricuspid disease was the most recent. The walls of the heart showed marked fatty degeneration.

Mr. CHURCHILL showed a specimen of Cranio-tabes from a child aged four, that died from congestion of the lungs. There was general rickety condition of the ribs, wrist, and tibiæ.

In a few closing remarks Dr. S. WILKS said that of all the interesting specimens shown during his presidency, those that struck him the most were the specimens of new growths; their whole structure was shown, their origin traced, and their relation to the normal growths explained. In this way there was hope that knowledge of the true mode of treatment, preventive and curative, might be attained; in his earlier years it was thought to be enough to examine into the histology only of such growths. Although the Society now suspended its meetings, its members he knew would continue their labours with unabated energy.

The following card specimens were exhibited:—Gummata of Brain, Cranial Bones and Spinal Cord, by Mr. F. Jordon; Osteo-sarcoma of Lower End of Femur, Cancer of Mamma following Eczema of Nipple, Drawing of a case of Cheiropompholyx, Sequestrum of Clavicle, by Dr. MacNaughton Jones; Ainhum, by Dr. Crombie.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Report of the Committee on Excision of the Hip-joint in Childhood.—Aortic Aneurism.—Anorexia Nervosa.—Antiseptic Osteotomy of the Tibia.

THE ordinary meeting of the Clinical Society of London was held on Friday, May 13th, Joseph Lister, Esq., F.R.S., in the chair.

Mr. HOWARD MARSH presented the Report of the Committee appointed to inquire into the value of Excision as a means of treating disease of the Hip-joint in Childhood, of which the following is an abstract. The points specially investigated were:—1. The indications for the operation; 2, its results; 3, the method of operating; and 4, the nature of the disease. In 45 cases treated by excision there was a total mortality of 35·5 per cent. from causes connected with the disease; 13·4 per cent. from some form of tubercular disease; the average duration of treatment was 1¾ years; the average shortening amounted to 2¾ in., while the movement at the hip was free, limited, or *nil* in the proportion of 11, 6, and 3. In 260 cases of suppuration treated without excision, there was a mortality of 30·4 per cent. counted as above, 9 2 per cent. from tubercular disease, an average period of treatment of 2½ years, with an average shortening in 33 cases of 1·6 in., and in 35 of the cases 30 walked with slight or no limp, 5 with considerable limp; the movement was free, limited, or *nil* in the proportion of 5, 4½, and 3. In 124 cases without suppuration the total mortality was 10·5 per cent., 7 per cent. from tubercular disease, and the movement was free, limited, or *nil* in the proportion of 5, 3, 3; in 17 of these cases the average shortening was 1·4 in., and in 1 there was apparent lengthening of ¾ in.; of 22 of them 19 walked well, and 3 limped. Sequestra were found in 59 per cent. of the specimens of the disease examined. Of a total of 203 cases of excision collected from various sources 13·7 per cent. died directly from the operation. The pathological indications for the operation are stated to be necrosis of head of femur, or formation of large sequestra, extensive caries of the bones, intrapelvic abscess from acetabular disease, and long-continued suppuration. The clinical indications are—rapid onset of suppuration, with severe local and constitutional symptoms, general albuminoid disease and long-continued suppuration in spite of other treatment. Pelvic disease is no bar to the operation. The mortality from tubercular meningitis, in cases of excision, was 4·4 per cent., in other cases of suppuration 6·1 per cent., in cases without suppuration 5·6 per cent. Of 429 cases 9 per cent. died from some form of tubercular disease. The limb is more generally less useful after excision than other modes of careful treatment. Only the diseased bone should be removed, and the great trochanter only when diseased or when there is extensive disease of the pelvis. While the occurrence of necrosis is shown to be proportionately very large, clinical records show that, in many instances, these sequestra are small, and either come away by themselves or are very easily removed in general operations.

Dr. WHIPHAM read a paper on a Case of Aortic Aneurism encroaching on the Trachea at its bifurcation, demonstrated during life by the Laryngoscope. A carpet cutter, aged forty-nine, was admitted into St. George's Hospital, under Dr. Wadham, on March 7th, 1881, almost speechless, and suffering severely from dyspnœa. The man had never had any serious illness, and had not suffered from syphilis. There was no history of asthma, and his occupation did not involve any severe strain. He had never before experienced an attack like the one for which he was admitted. He had for some weeks suffered considerable pain under the right scapula, for which he had been treated for dyspepsia. On the morning of March 7th, when he was going to his work, he was suddenly seized with a most severe attack of dyspnœa, which rendered him speechless and almost unconscious. He was brought at once to the hospital, and on his admission at 8 A.M. was in a state of extreme dyspnœa, ashy pale, unable to speak, and heedless of anything said or done. His hands were cold and his breathing stridulous. Leeches were applied to the throat, and he was ordered a mixture of ether and chloroform. By 10.30 A.M. his respiration had become perfectly natural, and his voice, though weak, was natural in tone. The heart was not obviously out of position; a systolic bruit was heard over the base, and to the right of the sternum. No abdominal pulsation or thrill was detected. The pulses in the radial arteries were equal and rather hard, 126. Wheezing, stridulous sounds were audible throughout the chest. At 2 P.M., at Dr. Wadham's request, Dr. Whipham made a laryngoscopic examination. The vocal cords were faintly pink, but there was no swelling of the larynx, and all movements of the cords were perfect. The first two or three rings of the trachea were visible, and normal in appearance; but below them, about three inches below the cords, the posterior wall of the trachea was bulged. The mucous membrane covering this swelling was much congested. At 4 P.M. there was a sudden recurrence of dyspnœa, and, without the least aggravation of the patient's distress, a second laryngoscopic examination was made. The bulging of the trachea was visible, as before, and the movements of the larynx were perfect; in fact, the extent of abduction of the cords was unusually great. The various remedial measures proved unavailing, and the patient was suffocated at 8 P.M. At the post-mortem examination an aneurism was found, involving the descending portion of the aortic arch and the commencement of the thoracic aorta; from the right of the upper part of the sac a secondary aneurism with thin soft walls arose, and this second sac had flattened and produced a certain amount of atrophy of the œsophagus, that caused the bulging seen just above the bifurcation of the trachea. The diagnosis during life was that a tumour (in all probability an aneurism) was the cause both of the appearances and symptoms, and the case was adduced as being a rare instance of actual demonstration of an aneurism pressing on the trachea at its bifurcation. The sudden access of the symptoms was possibly explained by rapid dilatation of the thin walls of the secondary aneurism.—Dr. C. WILLIAMS asked whether there were not any physical signs of the aneurism along the spine; in the cases he had seen there was generally some bruit, and usually a tubular sound over one scapula. An aneurism presenting and pushing forwards in such a way was very rare.—Dr. SEMON thought Dr. Whipham very fortunate in his case, for too often the physician cannot determine the seat of the obstruction. He had seen a case with Dr. Ord in which there was bilateral incomplete paralysis of the abductors of the larynx, but there was no local sign of aneurism, and the difficulty was to decide if any other source of obstruction existed lower down. Tracheotomy was performed, and the patient died ten days later from rupture of the aneurism which pressed on the trachea and both bronchi. He thought he had found that the inferior laryngeal nerve was differentiated, and that each laryngeal muscle had its own ganglionic centre, and that there was a tendency on the part of the nerves supplying the abductors to become diseased more quickly than the other branches of this nerve; much clinical and pathological evidence of this had been met with by him. Thus, paralysis of an abductor muscle was far more common in ascending or descending degeneration, and from pressure of the nerve-trunk on any part of its course, while functional disease, such as hysteria, has a similar proclivity to affect the part of the nerve supplying the adductor muscle. Professor Elsberg of America has observed that during convalescence after complete paralysis of the inferior laryngeal nerve, the adductor muscles are the first to show signs of recovery, and this fact may cause serious symptoms during true convalescence.—Mr. GOLDING BIRD had recently met with a similar case in Guy's Hospital, in which a pulsating tumour existed at the root of the neck, which on coughing was pushed up and ceased to pulsate. Dr. Wilks diagnosed an aneurism. He was readmitted under Dr. Fagge. Mr. Lane, the house-physician, observed during an attack of dyspnœa a bulging inwards of one side of the trachea. The right pulse was smaller than the left. The larynx was very easily examined, the abductors were acting to the full, the right side of the trachea was seen more plainly than the left. He cut down upon the tumour and found it was aneurismal, and then ligatured the common carotid artery. After death a perfect innominate aneurism (not affecting either of its divisions) was found, bulging inwards the trachea; there were other aneurisms in various parts of the body.—Dr. ORD had twice seen the vocal cord adducted in cases of aneurisms pressing upon the left recurrent laryngeal nerve. At present he had a case with hoarseness and permanent adduction of one cord, and other symptoms pointed to an aneurism of the arch of the aorta. The laryngoscope was useful not only for diagnosis, but also for practice to decide upon the probable value of tracheotomy.—Dr. LONGHURST had often observed extremely sudden attacks of dyspnœa in cases of aortic aneurism, and he asked how it was that an aneurism could exist in such a situation for years without any symptoms. Did Dr. Whipham observe the state of the pupils? What was the actual cause of death?—Dr. WHIPHAM replied that an accurate examination of the patient's chest was impossible owing to his condition. The laryngoscope had saved the man from tracheotomy. There was no difference in the tracheal swelling during the attack of dyspnœa. The pupils were not noticed. The patient died of suffocation.

Dr. DOWSE read notes of a Case of Anorexia Nervosa. A. J——, aged fourteen, was admitted into the Hospital for Epilepsy and Paralysis on July 5th, 1880, with the following history:—Family history good. Her parents are healthy and strong, and so are her brothers and sisters. She was always considered to be a delicate child, and during her infancy cod-liver oil was given her on account of her weakness. In the early part of last summer she began notably to decline, stating that she could not swallow food, and exhibited great obstinacy of disposition. She would cry at the slightest opposition to her wishes, and often without any apparent reason. Being a delicate child she had always been treated with more indulgence than the rest of the children, and in her sullen fits at this time she would never speak to her mother, except in tones of the greatest violence. She grew from bad to worse, and in February last year she went thirteen days without taking anything besides a little water, at least not to anybody's knowledge. She became so weak that her parents sat up with her for nearly a week, and one night she was thought to be dying. It is supposed she had a fit on one occasion, and it was thought she was dead. She would never begin a conversation or join in one, and it would sometimes be difficult to get a reply from her. Her aversion to food of any kind was most marked. On admission to the hospital she was unable to stand without help. Her eyes downcast, cheek-bones prominent from wasting, angles of mouth depressed; she looked the picture of misery. Voice scarcely audible; she was taciturn, shy, and reserved. There was a general morbid state of functional inactivity; all her movements were slow, and her mind was equally inactive. The breath was offensive, the tongue fairly clean, the bowels obstinately confined, and the evacuations were pale and clay-coloured. The temperature was never over 98° F., and frequently below it. The extremities were cold and of a bluish colour. The special senses were normal. Pupils sluggish. Pulse 120, respiration 20. There was no marked anæsthesia of the fauces, no globus, or other hysterical symptoms. Upon her admission considerable difficulty was experienced in getting her to take food, but forcible feeding was never had recourse to. She was in the hospital for two months, and her condition upon admission and departure was very striking and characteristic. She had gained considerably in weight, and instead of being taciturn and reserved she was cheerful and agreeable to all about her, and took food without any reserve or hesitation. The cure was brought about by the frequent administration of fluid nourishment. It was made compulsory for her to take in twenty-four hours three eggs, one pint of beef-tea, three pints of milk, and three ounces of brandy. No medicine was given, except half a drop of croton oil occasionally.—Dr. C. WILLIAMS had seen several examples of this disease, which had been brought to him as cases of phthisis. They are very cold and clammy to the touch, with a slow pulse; they are never febrile, and there are no physical signs of phthisis. The diagnosis is easy, but the management of them is very difficult. Mental treatment is very useful, but forcible feeding is often needful, and the nutritive enemata are the best means of applying force.

Mr. PEARCE GOULD read a paper on a Case of Antiseptic Osteotomy of the Tibia, in which rapidly fatal carbolic intoxication occurred. A lad, eight years of age, of robust appearance, was admitted, under his care, into Westminster Hospital in Oct. 1880, with rickety deformity of the legs, especially of the left tibia. Other treatment had been perseveringly tried at the National Orthopædic Hospital for some time without avail, and he was sent in for the purpose of having osteotomy performed. His general health was very good. On Oct. 30th chloroform was administered, and the left tibia divided with McEwen's chisel, with a careful observance of the details of Listerism. He quickly recovered from the effects of the chloroform, and slept well through the night; next morning (Oct. 31st) he took his breakfast and appeared quite well; temperature 98·4°. At 11 A.M. (twenty-one hours after the operation) he vomited; and vomited a watery fluid repeatedly up till 9.30 P.M. He also passed two orange-coloured loose stools. At 7 P.M. he was rigid, and at 8 P.M. very restless; at 9 P.M. he was almost unconscious, he was breathing hurriedly, pulse almost imperceptible at the wrist. At 10 P.M. Mr. Gould saw him; he was then conscious; lying quiet and quite flat, respiration 44 per minute, air entered lungs freely, pulse very small and rapid, pupils small. He died, asphyxiated, at 2.30 A.M., Nov. 1st, thirty-six hours and three-quarters after the operation. There was complete suppression of urine after 11 A.M. Temperature rose to 100·2°, and fell to 99·6° at 2 A.M. on Nov. 1st. The treatment consisted in the application of warmth and stimulants to the surface, and brandy internally. At the autopsy all the viscera were apparently healthy, with the exception of congestion of the tracheal and bronchial mucous membrane, and excess of mucus in these tubes, and slight congestion of the lungs. The left side of the heart was empty, the right side contained partly-clotted blood; blood in smaller veins all fluid, in the larger partly in soft clots, all of it black. No petechiæ; no staining of endocardium or intima; no sign of fat embolism. Bladder empty. A small blood-clot in the wound; no crushing of the medulla; no thrombosis of tibial vessels. Microscopic preparations of the organs were made for Mr. Gould by Dr. Heneage Gibbes, some of which were shown at the meeting. From these it was seen that there was thrombosis of the capillaries and smaller vessels of the lungs with minute spots of round-cell inflammatory exudation. Similar minute inflammatory foci were also found in the kidneys, while sections of the stomach showed intense inflammation of its mucous surface, only traces of its glands being visible, and at places the process was evidently advancing to suppuration. No sign of fat embolism. In discussing the cause of death Mr. Gould pointed out that shock, chloroform, the acute specifics, erysipelas, septicæmia, pyæmia, and fat embolism, might be excluded, as was also the ingestion of any irritant matter, but yet both the symptoms and pathological changes showed evidence of the circulation of some irritant in the blood. The symptoms were individually considered, and it was shown that the vomiting, diarrhœa with orange stools, collapse, rigidity, restlessness, loss of consciousness, very hurried respiration, slight rise of temperature, and death from asphyxia, were the symptoms observed in cases of undoubted carbolic intoxication. The urine passed before the onset of vomiting appeared to be normal, and was not preserved; the suppression of urine later on was a new fact in such cases. The softly coagulated and black blood had been noted before, but there was no record of any microscopical examination of the apparently healthy organs usually found. The quantity of acid absorbed was no doubt small, and the great susceptibility of the patient to its toxic effects must at present be spoken of as an idiosyncrasy; but from the absence of other cause, and of any facts to negative the supposition, as well as the agreement of the symptoms and post-mortem pathological changes in the main with those observed in cases of carbolic intoxication, he was forced to the conclusion that such poisoning was the cause of death.—Professor LISTER remarked upon the interest attaching to the suppression of urine, which he had not met with before. He had no doubt that Mr. Gould's view must be accepted, that this patient was one of those who had an unfortunate susceptibility to the toxic effects of carbolic acid. He had met with cases of such susceptibility, and one he called to mind was a lady whose breast he removed and dressed in his usual manner; intense symptoms of carbolic poisoning came on, and boracic lint was substituted for the gauze, dressing, but the spray was used when the lint was changed and this was sufficient to keep up the symptoms, which only abated when its use was discontinued. As an instance of the special local susceptibility of some patients, he mentioned a case of chronic synovitis of the knee-joint, which he opened and dressed antiseptically, and next day he found all the skin under the gauze intensely red and irritated. It had been stated that there was no antiseptic that could with safety replace carbolic acid, though several had been tried; but he was in a position to say that the oil of Eucalyptus globulus, if used properly, is a powerful and perfectly reliable antiseptic, and is also quite unirritating and without toxic effects. If the oil be made into an emulsion with spirit and water, and then used, it very quickly evaporates; but he had found that gum dammar holds it exceedingly well, and the mixture remains soft and strongly odorous of the oil even at the end of several weeks. He had used a gauze prepared with a mixture of one part of the oil, three of dammar, and three of paraffine, and he was able to assert that it might be thoroughly trusted as an antiseptic where carbolic acid was inadvisable.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Villous Polypus of Rectum.—Muscular Atrophy.

AT the meeting on April 25th Dr. Broadbent, President, in the chair, Mr. GOODSALL exhibited an adult male, who was under his care at St. Mark's Hospital, suffering from a large villous polypus of the rectum. The mass was about the size of an orange, and was rough and tuberculated on the surface. There was a frequent and copious watery discharge from the rectum, but the man had never lost more than half an ounce of blood at any one time, nor was he losing flesh in any marked degree. Mr. Goodsall had seen several such cases. In this instance the disease had been treated elsewhere as one of simple diarrhœa, no exploration of the bowel having been made. The pedicle of the tumour was well within the reach of the finger, and now of sufficient length to allow of the painless extrusion of the mass.—Dr. DE HAVILLAND HALL asked if in the other cases referred to there had been any recurrence of the growth after operation.—Mr. EDMUND OWEN remarked upon the necessity in any case of irritation of the rectum of making a thorough exploration of the bowel by the finger; in this manner only could a small villous growth or vascular polypus be detected.—Dr. COUPLAND questioned the applicability of the term "villous" to the lobulated mass which formed this polypus.—The PRESIDENT asked concerning the nature of the discharge of the pale and odourless fluid, and also what line of treatment would be followed.—Mr. GOODSALL, in reply, remarked upon the comparative rarity of the disease, and upon the peculiar watery discharge. He knew of no instance of recurrence after removal, and intended treating this by transfixing the base and securing the parts of the pedicle in three fine ligatures.

Dr. ALLEN STURGE read a paper on Muscular Atrophy, and exhibited two patients suffering from progressive muscular atrophy to illustrate his remarks. He began by giving a brief account of the condition leading to muscular atrophy, whether acute or chronic, stating that in either case the condition might be due to disease of the anterior horns of grey matter in the spinal cord, to disease of the anterior roots of the nerves, of the trunks of the nerves, or to disease of the muscle structures themselves. He called special attention to the fact that atrophy tends to affect groups of muscles in a limb rather than the limb as a whole, thus differing from other forms of paralysis. Muscles may be grouped in two ways: (1) anatomically—i.e., according to their position in a limb, or according to their nerve-supply; (2) physiologically, according to their association in function. When atrophy results from disease of the anterior horns, the muscles are affected according to their physiological grouping; when it is due to disease or section of a nerve, they are affected according to their anatomical grouping. This tends to prove that the centres in the spinal cord for the various muscles are arranged so that the centres for a set of muscles habitually employed together shall be contiguous to one another, and together form a large centre for the coördination of these muscles to produce some of the more automatic actions. Dr. Sturge then passed on to compare the acute with the chronic forms of muscular atrophy, stating that in the acute disease there is no tendency to symmetry, which, on the contrary, is often present in the chronic form of muscular atrophy; that in the latter there is not unfrequently seen a tendency to simultaneous affection of homologous groups of muscles in the upper and lower limb; that in the acute all parts of a muscle are affected in about the same degree, whereas in the chronic disease some bundles of muscular fibre are entirely destroyed, whilst others may be little, if at all, affected. This points to the presence, in the acute affection, of a gross lesion attacking a whole spinal centre at once. In the chronic affection individual nerve cells are attacked and destroyed, whilst others in their immediate neighbourhood are left untouched. In other words, the acute affection attacks the centre *en masse;* the chronic attacks it in detail.—The PRESIDENT remarked on the great value of Dr. Sturge's paper, and on the excellent way in which he had worked up the clinical and pathological details in one continuous account.—Dr. SYMES THOMPSON remarked on the question of chronic muscular atrophy depending upon central or peripheral change. He would like to hear more upon the electro-therapeutics adopted in these cases. Many years ago he read a paper on the subject before that Society; much progress had since been made in the knowledge of this and allied affections.—The PRESIDENT expressed his individual thanks to the author, and remarked upon the interest of the physiological grouping of muscles affected in infantile paralysis. He had been inclined to question the central origin of infantile paralysis; it had seemed to him that the peripheral nerve-endings had been much neglected, and he did not understand how an acute inflammation spreading by continuity in the grey matter could so constantly respect physiological limits. He certainly thought that, in the chronic cases, the change was central rather than peripheral.—Dr. STURGE, in reply, remarked that with central disease the influence of electro-therapeutics must be limited. It might restore a secondary wasting, but could not restore the diseased tissue. He used both the continuous and the interrupted current, and preferred the one with which he found he could obtain the more energetic result. In some cases of infantile paralysis certain groups of muscles were clearly picked out.

Dr. GILBART SMITH exhibited three machines used in the mechanico-therapeutic institution of Stockholm, and also photographs of others.

The Society then adjourned.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Retinal Hæmorrhages with High Arterial Tension.—Paralysis of both Third Nerves.

THE ordinary meeting of this Society was held on the 12th inst., W. Bowman, Esq., F.R.S., President, in the chair. The following card specimens were shown:—1. Microscopical Sections from a case of Optic Neuritis in an eye lost by corneal ulcer, by Mr. W. Lang. 2. Tumour (sarcoma) at cavernous sinus, causing complete paralysis of all branches of the third, fourth, and sixth nerves without affecting either the optic or the fifth, by Mr. Nettleship. The following living specimens were also exhibited:—1. Intra-ocular Tumour coming on in a young man who was already blind from post-neuritic atrophy caused by cerebral tumours, by Dr. Allen Sturge and Mr. Anderson Critchett. 2. Double Ophthalmoplegia externa, without other symptoms, in a lad aged eighteen, by Mr. Nettleship. 3. Case in which several years after an injury an Opaque Lens became dislocated into the anterior chamber, and then passed, when the patient was recumbent, into a pouch which had been formed by separation of the upper part of the ciliary body from the sclerotic. Living specimens were also shown by Mr. Spencer Watson and Dr. Allen Sturge in connexion with their papers.

Mr. SPENCER WATSON read notes of a case of Retinal Hæmorrhage with High Arterial Tension. A married woman forty-five years of age, whose menstruation had been regular up to two months before, but who had since not menstruated, had dimness of vision in one eye, which was found to be due to an effusion of blood in the region of the yellow spot. The arterial tension was found to be high, and though palpitations had been complained of, and great pain in one side of the neck and the corresponding shoulder, there was no discoverable disease of the heart, and no aneurismal dilatation of the aorta. Mr. Watson, by the advice of Dr. Sansom, gave nitro-glycerine in very minute doses, and this had the effect of relieving the pain. There was, however, no improvement in the state of the eye. Mr. Watson regarded the case as an instance of one of the local hæmorrhages likely to occur in women at the change of life. It was accompanied in this instance by long-continued and profuse epistaxis on one occasion.—Dr. SANSOM had seen several cases coming under the same category, presenting a constitutional tendency to high arterial tension, as pointed out by Dr. Mahomed, whose views Dr. Sansom endorsed. Such a tendency might be independent of any other pathological condition. In these cases he had often seen retinal hæmorrhage sometimes with symptoms of vertigo, sometimes headache, or pain in other parts of the body. In the present case, the condition suggested contracted kidney, but of this there was no evidence, but then that disease was very insidious. He had at present under his care a gentleman who had had retinal hæmorrhages, which had passed off leaving but slight traces, with considerable high arterial tension, and an extreme form of migraine. In that case there was no evidence of renal disease, and all symptoms disappeared under careful dieting. The attacks of migraine were controlled by nitro-glycerine, in doses of about $\frac{1}{250}$ grain. In another case, a woman with retinal hæmorrhages and high arterial tension, the cerebral symptoms were of the nature of vertigo, not pain. In another case there was intense pain at the epigastrium, which was benefited by nitro-glycerine. The pulse tracing in that case indicated atheroma of the aorta. In reply to Dr. S. Mackenzie, he added that there was no symptoms nor history of gout, and in reply to the President that in all these cases there is some hypertrophy of the left ventricle and accentuation of the aortic second sound.—Mr. BRUDENELL CARTER suggested that there must be some structural change in the arterial walls to account for the hæmorrhages, which could hardly be brought about by high arterial tension, a condition more likely to produce anæmia; as in the case of a boy who presented a pallid disc and pulsating retinal arteries, and in whom Drs. Anstie and Sturges found high arterial tension.—Dr. GILBART SMITH inquired as to the character of the second sound over the aorta, and the evidence of ventricular hypertrophy, which may be taken as the measure of the arterial condition.—The PRESIDENT remarked that the tension might be high in some parts and low in others, and that such inequality might be the cause of hæmorrhage.—Mr. CARTER said that if the effect of high tension was to diminish the calibre of arteries, hæmorrhage could not be explained; but the hæmorrhage of embolism was an instance of its occurrence when the tension was unequal.

Dr. ALLEN STURGE read the notes of a Case of Paralysis of both Third Nerves after an Apoplectic Attack. The patient, a boy aged sixteen, was seized while at his work, bottling beer, with sudden severe pain in the head, and giddiness; two or three minutes afterwards he fell down unconscious. He was taken at once to the Royal Free Hospital. He remained more or less unconscious for twenty-four hours, after which it was discovered that all the muscles supplied by both third nerves were completely paralysed. The pupils were not dilated, and acted, although sluggishly, to light, but the right pupil was slightly larger than the left. There was no other paralysis of any kind present. There was no optic neuritis. He suffered much from pain at the back of the head; the temperature was somewhat raised. Three days after admission a slight weakness was noticed in the left external rectus, which, two days later, had increased to complete paralysis. Eight days after the first onset power began to return in the right levator palpebræ, and subsequently in the left levator palpebræ, and in the recti in both eyes. He was discharged seven weeks after admission with complete return of power in all the muscles. Dr. Sturge remarked that this case was analogous to one exhibited by him at an earlier meeting of the Society, in which a paralysis of both third nerves, in conjunction with other paralyses, had come on after an apoplectic attack. He gave reasons for concluding that in both cases the lesion involved the central connexions of the nerves, rather than the trunks of the nerves, in their course from the brain to the orbit. To explain the relationship which these cases bear to other forms of ocular paralysis he referred to the anatomical facts ascertained in regard to the nuclei connected with the motor nerves of the eyeball, laying stress upon the fact, that although the chief mass of fibres forming the nerves appear to come from the so-called nuclei of origin, yet that in the case of the third nerve, at any rate, some fibres do not pass through the nucleus of origin of the nerve. When studied in the light of physiological experiment, it becomes evident that these nuclei of origin are not the sole portions of grey matter connected with the movements of the eyeballs, centres having been discovered which control the upward movements of the eyes; others controlling the lateral movements and so on. Independent centres for accommodation, for dilatation of the pupil and for contraction of the pupil, had also been ascertained to exist. All these centres had to do with bilaterally coördinated movements, and the grouping of fibres and cells in them corresponds to the coördination of muscles rather than to the association of fibres in the oculo-motor nerves. *A priori* reasoning would lead us to suspect that we should have three types of oculo-motor paralysis :—(1) The true peripheral paralysis of eye muscles from involvement of the trunks of the nerves. (2) Paralysis due to lesions involving the nuclei of origin of the nerves, which would resemble the peripheral paralyses in many respects, but would present points of difference, for these reasons : (*a*) that all the fibres of the nerves do not emanate from the nuclei of origin ; (*b*) that there are good reasons for believing that a low degree of coördinated association of muscles takes place in the nuclei of origin. (3) Paralysis due to lesion of the higher coördinated centres. In this type the association of the paralysed muscles would have ceased to correspond with nerve supply. Of this type there would be several varieties—e.g., (*a*) the paralysis might affect muscles involved in a single coördinated action alone, as the two superior recti ; (*b*) the paralysis might involve all the muscles of the eyeball *except* those used in a single coördinated action—all except the two levatores palpebrarum, for example ; (*c*) the paralysis might affect the centres for accommodation or for the pupils alone, or it might affect these in conjunction with some or all of the external muscles. Dr. Sturge then went on to consider to what extent these varieties are met with in practice, beginning with paralyses of the third type. In proof of the existence of the varieties (*a*) and (*b*), he quoted cases published by Mr. Hutchinson, Dr. Gowers, and Mr. Nettleship—cases to which Mr. Hutchinson has given the name "ophthalmoplegia externa." As examples of the existence of the variety (*c*), he quoted the cases described by Mr. Hutchinson under the name "ophthalmoplegia interna," which Mr. Hutchinson had attributed to disease of the ciliary ganglion. He mentioned that Dr. Gowers had suggested that the latter cases are really due to disease of the central nuclei governing the iris and ciliary muscle ; and he made an analysis of Mr. Hutchinson's cases to show that they contain internal evidence that Dr. Gowers' explanation is almost certainly the correct one. Clinically, there are six varieties of this type of paralysis, corresponding closely to those which might be suspected on *à priori* grounds to exist. These are, paralysis involving : (*a*) accommodation alone, (*b*) accommodation + pupils, (*c*) accommodation + pupils + external muscles, (*d*) pupils alone, (*e*) pupils + external muscle, (*f*) external muscles alone. His own two cases of paralysis after apoplexy he believed to belong to the second type of disease, involving the nuclei of origin, giving reasons in favour of this view; and he called attention to certain points in the cases which threw light upon the physiology of these nuclei.—The PRESIDENT, in thanking the author for his valuable and interesting paper, hoped that the subject might again be raised at some future time when Mr. Hutchinson could be present.

The Society then adjourned to July 6th.

Reviews and Notices of Books.

The Cat. An Introduction to the Study of Backboned Animals, especially Mammals. By ST. GEORGE MIVART, Ph.D., F.R.S. With 200 Illustrations. pp. 557. London: John Murray. 1881.

EVERY student of biology must have learnt at an early period with surprise and regret how few monographs exist in our own or in any foreign language of even the commonest animals. In the larger text-books of comparative anatomy the general features of each class are given, and the prominent characters of particular members receive brief notice, but any point on which information is sought is sure to be omitted, and if he live where he has no access to the museums of a large centre, it is probable that he must at great loss of time work out the point for himself. The only animal which up to a recent period could be said to be even fairly well and fully described is the horse, in a work written by a distinguished army veterinary surgeon, William Percivall, nearly half a century ago. More recently the translation by George Fleming of Chauveau's treatise on the comparative anatomy of the domesticated animals, which treated mainly of the horse, ox, and sheep, but gave also many details of the anatomy of the pig and dog, proved a very valuable addition to our literature, and Ecker has supplied a partial and, so far as it goes, excellent account of the frog. We have now before us a monograph on the cat, which supplies what was greatly needed—a description by a competent anatomist of a typical member of the carnivora, and which from the care and accuracy with which it has been completed has evidently been a labour of love to its distinguished author. Mr. Mivart states that his present treatise on the zoology of the cat is the precursor of a companion volume in which the natural history of the entire class of mammals will be treated of. Such a manual worked up to the present day is much needed.

The early history of the domestic cat is uncertain. It is not the common cat of zoology, which is the wild or native cat, an animal that existed abundantly in the forests in the time of Julius Cæsar, and was seen in Wales within the last twenty years. It appears to have come down to us from the Egyptians, being mentioned, Mr. Mivart informs us, in inscriptions as early as 1684 B.C., and being, as is well known, an object of religious worship, and the venerated inmate of certain temples. It was an emblem of the sun to the Egyptians, and according to Herodotus the death of a cat from natural causes was followed by the ceremony of shaving the eyebrows in token of mourning. From Egypt it must have been introduced into Greece, though Professor Rolleston, in his article on Cats in Humphry and Turner's *Journal of Anatomy*, considers that the cat of the ancients was the *Mustela foina*, the "beech" or "stone" marten. It was not a domestic animal amongst the Hebrews, though it was known to them, as we read in the apocryphal book of Baruch, who lived, it is supposed, in the reign of Jehoiakim, about 600 B.C., that "upon their bodies and heads sit bats, swallows, and birds, and the *cats* also."

The main body of the work is occupied with a thorough, complete, and systematic account of the anatomy of the cat, each bone, muscle, nerve, artery, and organ being described, while space is found for a concise history of its development, and for the chief facts in regard to its histology. Numerous and carefully executed drawings illustrate the text. The chief kinds of cats are described zoologically, including those of the Old World—as the lion, tiger, leopard, ounce, clouded tiger, cheetah, and caracal, and those of the New World—as the puma, jaguar, ocelot jaguar, eyra, and colocollo, with the lynx, which is found in both hemispheres. The fossil forms of machaerodus, hoplophoneus, nimravus, and dinictis are also described—genera which have been found in Nebraska and other parts of the American continent in miocene deposits. Nor have even the parasites of the cat been overlooked, a short section being devoted to the olulanus, the most important of all the feline nematodes, the tænia, and the pentastoma, with the flea, louse, and itch insect. One of the most interesting chapters of the work relates to the pedigree and origin of the cat. In this Mr. Mivart maintains consistently the doctrines he has advanced in his "Genesis of Species and Lessons from Nature," and which are by no means in accord with the prevalent Darwinian views. In regard to its pedigree he traces it from unknown insectivora-like animals which produced, among other forms, arctocyon. From this, as a root, the carnivorous branch divided into cynoid and arctoid branches—the former developing into the typical canidæ ; the latter, after giving off other branches, leading to the ursidæ, and through proelurus to the viverridæ, hyænidæ, cryptoproctidæ, and felidæ. In regard to the origin of the cat, Mr. Mivart has the following observations, which express very clearly the various modes in which the evolution of new specific forms may have been brought about :—1. The change may have been due, he says, first, entirely to the action of surrounding agencies upon organisms which have merely a passive capacity for being indefinitely varied in all directions, but which have no positive inherent tendencies to change, or vary, whether definitely or indefinitely; secondly, entirely to innate tendencies in each organism to change in certain directions; thirdly, partly to innate tendencies to vary indefinitely in all directions, and partly to limiting tendencies of surrounding conditions which check variations, except in such directions as may happen to be accidentally favourable to the organisms which vary. Fourthly, partly to innate tendencies to vary indefinitely in all directions, and partly to external influences, which not only limit but actively stimulate and promote variation. Fifthly, partly to tendencies inherent in organisms to change definitely in certain directions, and partly to external influences acting only by restriction and limitation on variation. Lastly, to innate tendencies to change definitely in certain directions, and partly to external influences, which in some respects act restrictively, and in other respects act as a stimulus to transformation. Mr. Mivart himself holds that the genesis of new species is due mainly to an internal cause, which may be stimulated and aided, or may be more or less restricted, by the action of surrounding conditions, and he devotes several pages to the explanation and support of his previously expressed opinions. His argument is of great weight, and may fairly claim the adhesion of those who hold the doctrine of a Divine Creator acting through secondary laws in opposition to atheistic conceptions, under which category, however, the doctrine of Darwin cannot in any way be included. We have great pleasure in warmly recommending the work to all who are interested in zoology and natural history.

Notes on Antiseptic Surgery in War. By Surgeon-Major H. MELLADEW, Royal Horse Guards. Pp. 36. 1881.

SURGEON-MAJOR MELLADEW took advantage of his winter leave to visit the military hospitals in Berlin, Dresden, St. Petersburg, Moscow, Vienna, Munich, and Paris, for the purpose of studying the system of foreign military hospitals and "to gather hints about antiseptic surgery as applied to service in the field." In the pamphlet before us he has published the substance of his inquiries on the latter subject. He has come to the conclusion that the system must be extended to the wounded on the battlefield, but in a modified form, owing to the disproportion between wounded and surgeons, and also to the impossibility of providing the necessary equipment for its full employment on the battlefield. It appears that many of the surgeons are of opinion that spray diffusers may be dispensed with, but the important condition of scrupulous cleanliness of hands, instruments, &c., must be strictly enforced, with the use of antiseptic dressings, and abstention from unnecessary probing or fingering the wound. The author goes into some detail with reference to the various disinfectant dressings recommended by Professors Esmarch, Nussbaum, Neudörfer, Bruns, and Münnich, and gives a description of a "soldier's packet," devised by himself, which seems to him to answer all requirements. The subject is one which is to be discussed in the section for military surgery and medicine at the forthcoming meeting of the International Medical Congress. In view of this our author's notes are well timed, and will be found useful as showing in a condensed form the conclusions arrived at on the Continent as the result of actual experience of the system on active service.

AT a late meeting of the Woolwich Board of Guardians, a committee was appointed to inquire and report on the system of nursing adopted at the London, Charing-cross, and Great Northern Hospitals, with a view to the improvement of the nursing at the union infirmary.

THE OLD UNIVERSITIES AND THEIR MEDICAL DEGREES.

To the Editor of THE LANCET.

SIR,—I trust you will grant me space to criticise a statement likely to give rise to a good deal of misapprehension made by "A Cambridge Undergraduate" in his letter of the 14th inst. He there says—"Of Oxford I know nothing personally, but of Cambridge I may say this, that the practical hospital teaching is such that the majority of Cambridge students know no more of practical medicine and surgery *after four years' attendance* on the practice of Addenbrooke's Hospital, than an average London student knows after the first six months of his attendance in the wards of his hospital." From this statement one would suppose that the hospital teaching was extremely bad. Now, Sir, I and others with whom I have spoken, who, like myself, have studied both at the Addenbrooke's Hospital and afterwards at a large London Hospital, know that this is far from the fact. "Undergraduate" confesses that he knows nothing of the Oxford school, but when he speaks of Cambridge men spending four years at the hospital there he shows plainly that his knowledge of the Cambridge school is not much greater, for as a fact Cambridge students attend hospital practice for from two and a half to three years at the outside, and then pass on to a London hospital to *dress*, *clerk*, and gain a wider experience. The majority, I grant, do not learn much, not because the teaching is bad, but because they have before them triposes and other examinations which principally engage their attentions.

On the other hand, what is the state of the knowledge of the ordinary London student, as far as practical medicine and surgery are concerned, near the end of his second year? I have frequently found that he takes little interest in, and learns less at, the out-patient practice he is compelled to attend. The majority of second-year students know nothing of the therapeutic action of the drugs they see prescribed, or of the pathology and symptoms of the diseases which are brought before their notice; and I am not surprised, because, as they themselves own, their examinations in anatomy and physiology require their almost undivided attention, so that, as a matter of fact, the Cambridge student, having attended for two years and a half at the Addenbrooke's, finds when he passes on to London that he is but little behind London students of the same standing. Not unfrequently, however, men, after passing their second M.B., spend their long vacation and part of September at the Cambridge Hospital, and are then able to give their undivided attention to the work; and I have repeatedly heard them say that they have never met with a *better teacher* than Dr. Humphry, nor one who requires cases to be taken more thoroughly and accurately. As far as the rest of the staff are concerned I can bear ample testimony to their extreme willingness to teach those who show the slightest desire to learn. Therefore, let no one be dissuaded from becoming a Camb. medical student on the ground that the hospital teaching is bad.—Yours truly,

A CAMBRIDGE B.A.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

To the Editor of THE LANCET.

SIR,—The annual election of pensioners and foundation scholars in connexion with the Royal Medical Benevolent College will take place on the 23rd instant. In accordance with a recently passed resolution, a committee has recommended certain candidates as being most eligible for election, and a printed form to that effect has accompanied each balloting paper. My object in writing is to bring before the notice of the governors the fact, that out of the whole list of candidates selected by the "examination committee," not one is either a widow or child of a deceased subscriber. I do not doubt the urgency of the various cases thus recommended, but maintain that we should be just as well as generous, and not lose sight of the special claim upon us of the widows and orphans of those who by noble self-sacrifice and frugality supported the very institution their survivors are soliciting succour from.—Your obedient servant,

Commercial-road, E., May 17th, 1881. T. RICHARDSON.

THE LANCET.

LONDON: SATURDAY, MAY 21, 1881.

THE question of hospital reform is ripening. The public and the profession are alike agreed that the present system of hospital administration is seriously imperfect, and in some respects essentially vicious. The charges of alleged abuse of the metropolitan hospitals as charitable institutions are loud and frequent, and though they have no doubt been greatly exaggerated, they are by no means devoid of foundation. The abuse is, however, to some extent unavoidable, and is largely due to the manner in which medical relief at hospitals is at present administered. The complaint is repeatedly made that many persons attend the hospitals of London as out-patients, or are admitted as in-patients, who are not fit objects of charitable relief, and who can well afford to pay. This is in a measure true, but it is not always easy to decide what they can afford to pay. They may be able to pay the smaller charges of an ordinary practitioner, and perhaps have done so for weeks or months, but they cannot pay a physician's or a surgeon's fee for a private consultation, or if they are able to pay once or twice they cannot continue doing so for weeks or months. For a person desirous of receiving specially skilled advice there is no alternative between applying at a hospital for gratuitous relief or paying the customary fee of the physician or surgeon. As long as the relations of the public to hospitals and to the profession, on the one hand, and of the profession to the public and hospitals on the other, remain as they are, the kind of abuse now complained of must continue, and cannot well be checked. That the evil ought to be remedied everyone must admit, though there may not be an unanimity of opinion as to how this is to be done.

The deputation lately received by the Home Secretary dealt with a comparatively small part of the question of hospital administration. The Home Secretary himself took a larger view when he expressed his approval of the desire for an inquiry, even by a Royal Commission, as to all the London hospitals. We believe that nothing less than such an inquiry can grapple with the whole of the facts of the case. The system of hospital relief needs to be reconstructed, and in the process of reconstruction the interests of the profession will have to be considered. Sooner or later the plan of making some out- and in-patients pay a distinct charge will have to be tried, and in carrying out this plan it will be necessary to conciliate the rival sections of medical practitioners—namely, the physicians and surgeons attached to the hospitals on the one hand, and the general practitioners on the other. Whether the members of the medical and surgical staffs of hospitals should in all cases be paid for their time and service may be an open question, but no one can seriously maintain that this time and service should be given without remuneration to persons who are made to contribute towards the funds of the hospital for the advice they receive. When patients are made to pay it is certain the medical officers will have to be remunerated.

The matters that demand most attention and consideration just now, are whether all hospitals should continue as charitable institutions affording gratuitous relief or not; and whether the medical officers should be paid for their services to these institutions or not. Out of these considerations will arise many others—such, for example, as the difference between hospitals that offer facilities only for the relief of the sick poor, and those which, in addition, by being connected with a medical school, become centres for the training and education of medical practitioners. In any scheme of medical reform, these two classes of institutions cannot be placed in the same category. The essential *raison d'être* of the two is different, though their ultimate aim is not so dissimilar as some have imagined.

◆

IN the course of the recent controversy arising out of considerations of ethical propriety in regard to the consultation of orthodox professors of scientific medicine with actual or reputed homœopathists, nothing has so much surprised us as the inexplicable ignorance which prevails, not only throughout the lay community, but among medical men, as to the nature and effect of "homœopathy" and "allopathy" as medical theories. We have laid down the proposition that *similia similibus curantur*—or *curentur* as some would have it written—involves a fallacy. It would of course occasion no astonishment if this assertion were challenged, but it does not seem to be understood. Lest this strange circumstance should be due to some obscurity in our way of putting the facts, let us state them again. The homœopathist says, "I select a drug which if given in a large dose to a healthy person would produce symptoms *like* those of the case I am seeking to cure, and I give this drug, when found—in a small dose." The ordinary practitioner asks, "Why do you not give it in a large dose?" The homœopathist replies, "Because it would increase the symptoms I desire to remedy." In short, the homœopathist *avoids* the dose in which the remedy he selects is *homœopathic* to the disease, and gives it in a smaller dose. Now everyone knows that the "effects" of medicines differ with the doses in which they are exhibited, giving rise to "symptoms" which are seemingly contradictory, in large and in small doses respectively. It follows that the so-called "homœopath" does not practise on the principle *similia similibus curantur* (or *curentur*). He only resorts to the principle embodied in that aphorism in selecting his drug, and by so doing goes a roundabout way to discover the remedy, which lies close at hand, and which the "allopath," if there were allopaths (or antipaths), might claim as acting on the principle *contraria contrariis curantur*. We are anxious to make this plain to our readers, and especially to those who are interested in the present discussion, because it is the key-note to what we allege to be the *fallacy* of the homœopathic school; and it explains the reiterated assertion made by homœopathists, to the effect that remedies which they believe to act *homœopathically* are recommended by accredited authors in standard works on Therapy. It must be so. *All* remedies lie open to the charge or claim of being "homœopathic" if the homœopathist may class them by the effects they produce when given in one dose, while he employs them in another dose, of which the effect is totally different, and nearly always opposite.

Take the case of aconite. A moderately full dose of this drug will produce the local and general "symptoms" of fever and inflammation—if we may employ terms loosely. In a smaller dose its effects are such as to raise the tone of the vascular system, and, while acting on the skin, to reduce the local and general symptoms characteristic of the state called "feverish" and "inflammatory." What measure of *homœopathy*, then, can there be in selecting aconite for the "cure" of fever and inflammation because if given in large doses it will produce symptoms "like" those supposed to characterise these remedies, whereas it is given by the homœopath in a small dose, in which it produces totally different effects? It would be just as rational—and no more so—to assert that aconite produces the symptoms of fever and inflammation "allopathically" or "antipathically," because, being selected for its antiphlogistic effects when given in a small dose, it was followed by contradictory results when given in a large dose. Again, take the case of "nux vomica," another important drug claimed as "homœopathic." In large or full doses this medicine irritates the stomach and causes spasms. We are purposely using popular language in these definitions. If pushed far it will produce tetanic contraction of the muscles, and in toxic quantities the well-known phenomena of death by strychnia poisoning ensue. The homœopathist, recognising these effects of a large or accumulated dose, argues that the remedy will cure diseases exhibiting symptoms *like* those it produces. He therefore gives it for gastric disturbances; for dyspepsia, especially with spasm; and probably he would give it for the graver affections resembling those it is supposed to produce; and while he claims it as a "homœopathic remedy," he seeks to convict the ordinary practitioner of medicine because he, too, recommends it. Now, how do nux vomica and its preparations act in small doses? Why, as tonics to the muscular system. In short, the natural effect of a drug which is a powerful excitant when given in large doses is that of a gentle and restorative or strength-giving stimulant in small doses. The homœopathist affects to give the drug because it will produce the symptoms he desires to cure, but, we repeat, he avoids the dose in which it might produce these effects, and gives it in a smaller dose, in which its effects are directly contradictory. We might follow out the list of the Materia Medica in the same way. A small quantity of alcohol will stimulate the cerebral functions and quicken the intellectual and nervous functions, while a larger dose will depress and stupefy. A large dose of ipecacuanha will produce vomiting, while a small dose will act gently and restore the tone of the organ, thus allaying vomiting. A small dose of opium will excite, a large one acts as a sedative. In the same way large doses of "cathartic medicines" act as aperients, while small—or relatively small—doses produce constipation; or conversely, drugs which may be cathartic in small and moderate doses—as calomel—are distinctly sedative or constipative when given in large quantities. Scientific explanations of the way in which these apparently contradictory effects are produced by the same drug in different doses are ready to hand, but they have no place in this argument. Our immediate purpose is to demonstrate that the homœopath does *not* give his drug on homœopathic principles, and cannot claim it as homœopathic, because he employs it in doses which do not produce effects like, but widely *unlike*, the symptoms of the disease he seeks to cure. It follows that, so far as the *action* of remedies is concerned, homœopathy is a misnomer, and involves a fallacy.

We shall be curious to see how the homœopathists attempt to answer this objection. If they are honest men, they must confess that we are right, and that the *homœopathy* of their system concerns only the mode of selecting drugs, not their action. Should they take this ground, we shall then have to show that it, too, is untenable, because the selection of a drug by an inverse process of induction from its supposed effects can never be a sure or safe guide to its use. Moreover, it is unscientific to speak of a drug as producing "effects" or "symptoms" in the organism. In studying the properties of a medicine, it is always tried in the healthy, and the student of therapy knows well that there is nothing mysterious in the seemingly contradictory effects of different doses of the same substance, seeing that the so-called "effects" of a drug are the changes of state or modifications of function which take place in the organism under its influence or with its aid. The effects are not located in the drug! Before we can predicate any "property" of a drug, we must take into the account the properties of the organic state and functions with which it is to be brought into relation. For example, if a muscle fibre is inactive, a stimulant will either elicit healthy action, or excite it to morbid spasm, or paralyse it by exhaustion, in proportion to the organic state of the fibre, the integrity of its nerve-supply, and the amount of energy available for its use. It follows that the only *rational* way to try a drug is first in health and then in disease. In short, it is not possible to predict the "effect" which will follow its use until we have actually tested it first on a healthy and then on a morbid organism. The pretence of selecting remedies on any principle or theory of their mode of action in health alone is manifestly an affectation of the impracticable. The homœopathist does not choose his drugs on the principle *similia similibus curantur*, even making allowance for the fallacy we have already demonstrated. He falls back on his *experience*, and he knows perfectly well that he would not on any account give a drug in a dose in which it might be supposed to act *homœopathically*, because that would be to aggravate the symptoms he desires to relieve. And he would not give a drug, even in a small dose, simply because it produces "like" symptoms in a large dose, since it might so happen that a still larger dose would be required to produce the effects he desires to secure. In truth, so far as the homœopathist is a *practitioner* of medicine at all, he must and does employ drugs on rational and common-sense principles, and his parade of a special theory as to the action or selection of his drugs is schismatic as regards his profession, and an absurdly fallacious procedure as regards the public. We venture to suggest for the consideration of honest and intelligent thinkers now connected with "the homœopathic school," whether a recognition of the truth of our reasoning, and a consequent repudiation of the errors exposed, would not offer a timely occasion for reconcilement with the medical profession, on grounds welcome to both parties in this regrettable alienation and controversy.

PROBABLY the appointment of judiciously selected committees to investigate and report upon the whole or some particular question connected with the treatment of diseases is one of the highest functions of the Clinical Society. It certainly was one in which the late President took particular interest, and during his term of office several such committees were appointed and duly presented reports. But it will perhaps be generally admitted that the subjects of their investigation were in no case so generally important as that of the nature and operative treatment of Hip-joint Disease, which has been specially studied by a very influential committee for several months. Their report has just been presented, and while we print elsewhere an abstract of it, we would wish to notice here some few points suggested by it.

The first fact by which we are arrested is that the whole ground is by no means cleared, and some of the questions taken up are left pretty much where they were: e.g., the true nature of the change in morbus coxæ—whether it is strumous, tubercular, or "simple." Nor do we find in the main general principles insisted on, in any particular, a marked departure from the usual teachings of the schools on this subject. The one point in regard to the nature of the disease which is laid stress upon is the frequent occurrence of necrosis of the bones and the formation of larger or smaller sequestra, the percentage of such occurrences being placed at 59. Unfortunately we are not clearly told the data from which this conclusion is drawn—whether the specimens examined were only the parts removed in excisions and amputations, or whether they included other preparations in our museums; indeed we must express our conviction that in assigning any special percentage-frequency to the occurrence of necrosis the Committee have rendered their report liable to misunderstanding. Such a fact could only be ascertained by an examination of a series of specimens representing all grades and forms of the disease, the milder of which are but very rarely met with in our post-mortem rooms, and still more rarely preserved in our museums. Again, the treatment to which the unhappy subjects of this disease are submitted plays a very important part in its course. Too often the children are neglected in the early stages of the disease, when alone treatment can be thoroughly successful; or they receive such intermittent care that the resulting failure dissuades the parents from other and more patient efforts for recovery. We must not look upon any results which may be thus occasioned or modified as sequents of the disease alone, or as showing its inherent nature and course. We do not question the accuracy of the Commitee's result so far as it goes, but we desire to point out that it must not be deduced therefrom that necrosis to a greater or less extent does or must recur, from the nature of the affection, in 59 per cent. of cases of hip-joint disease. Necrosis, in fact, is but an accident in bone disease.

The doubtful points which it was hoped the Committee would clear up were—1st, the real benefits conferred by excision of the joint, especially as to its protecting the body from fatal tuberculosis, and the ultimate value of the limb for progression; and, 2ndly, whether there was any special form of the disease that could be clearly recognised, which was a reliable indication for excision. The answer made to the first inquiry is that in a number of cases which run their course without suppuration, tubercle in some one of its forms leads to the death of 7 per cent.; in cases with suppuration, and where excision is not practised, this disease is fatal in 9¼ per cent.; while in a series of cases that have been submitted to excision of the diseased structures, the mortality from tubercle in all its forms amounts to 13½ per cent. But excision appears to lessen the liability to tubercular meningitis, for in cases operated upon this form of tubercle occurred in 4½ per cent., in cases of suppuration not operated upon 6 per cent., and in cases without suppuration 5½ per cent. Until there is a clearer definition of tubercle than can be given now, and a more general agreement as to the changes to which the term should be applied, all inferences from such statements as the above must be drawn with diffidence. Are we to say that the tubercular diathesis caused the suppuration and led to such extensive disease that excision became necessary, or are we to view the facts in the other light, and maintain that the production of tubercle increased in proportion with the greater severity of the disease? Indeed, both views may be right. But, further, if phthisis plays, as no doubt it does, an important *rôle* in the causes of death, we must not ignore the fact that the treatment to which the severer forms of morbus coxæ are subjected is in many cases just that which predisposes to the outbreak of pulmonary diseases: the prolonged rest in bed, interfering both with the digestion, general nutrition, and particularly with proper performance of the respiratory function, must not be left out of sight; and if to this we add the greater pain and anxiety, we see at once that there lie outside the primary disease explanations for this varying tubercular mortality. The facts would seem not to warrant the view that the severer forms of the disease are dependent upon the tubercular diathesis; the difference in the tubercular mortality in the mild and most severe cases is too small to support such a great deduction. The statistics in reference to tubercular meningitis are, however, of special interest, as there is not the same difference of opinion as to the proper use of this term, as exists in other diseases, and the peculiar pathological changes have received a pretty uniform interpretation. It is also characterised by the presence of that particular form of tubercle—if, indeed, there be other forms—which has been shown to be produced artificially by inoculation experiments. We find that its frequency is but little different in cases that suppurate and those that do not; while it is distinctly less in the cases that have been subjected to excision, as if removal of the diseased part had an important bearing on the issue. We should be inclined therefore to correct the statistics as to tuberculosis in general by those relating to tubercular meningitis in particular, and to hold that inoculation may take place both from suppurative and non-suppurative arthritis, and that removal of the part lessens this danger.

This leads us to observe that the facts in this report do not lend support to the view that early suppuration, or suppuration at any period, is an indication of the tubercular nature of the primary disease. On the other hand, general pathological facts teach us that we may regard such a termination of the disease as an indication of either intensity of local action or diminished power of resistance—which may be a purely local or a general phenomenon,—or of both of these conditions combined. Constitutional deficient power of resistance may be fairly held to explain the cases of so-called tubercular disease in which the pathological change is not the development of grey granulations. We arrive at the same conclusion if we view the same facts in another light. If the cases of suppuration were examples of tubercular ostitis, and those of non-suppuration of simple ostitis, over and above those instances in which from either form of disease inoculation of tubercle in the cerebral membranes might be supposed to occur, there would be a certain number—and the history of general tuberculosis shows it to be a large number—of cases in which those membranes would be affected contemporaneously with the primary tubercular affection of the bones; while such is shown not to be the case. The value of excision from this point of view, then, is that it removes a distinct source of "tubercular inoculation." Before leaving this part of the subject we must express our fear lest this report should give any sanction to the opinion that the disease, as it affects the hip-joint, is different from that met with in the knee and other articulations. The pathological processes are inherently the same, modified only by certain local peculiarities, the most important of which is that the necessary mechanical treatment only too often entails confinement to the house if not to bed, while the same disease attacking the elbow or the shoulder does not prevent the patient having due exercise and fresh air. The conditions are simpler therefore in disease of the joints of the upper extremity, and pathologists would do well to bring their particular views to the test of these affections, rather than study exclusively the disease as it affects the knee or hip.

We can only further note that the report of the Committee bears out Mr. HOLMES'S view, which he expressed at Cambridge, that the limb left after excision is more often an imperfect one than that after recovery without operation, even where suppuration has occurred. When it is remembered that it is the humbler classes that afford the very large majority of cases of morbus coxæ, the great, almost paramount, importance of this consideration becomes apparent. Rigidity is the great requisite in the lower limb, and to some it may well seem that even the saving of life itself hardly compensates for the life-long burden of a useless limb.

THE great problem of medical reform is to reduce the number of mere licensing bodies, and to improve the conditions of obtaining a licence to practise medicine. We showed last week that centuries ago the notion of licensing to practise medicine was very like the notion of licensing to sell spirits or beer—a local affair, and an affair of money-making. It has ceased now to be a local or parochial matter merely, but it still continues to be an affair of money-making. The licensing bodies still depend on the money they make by licensing. At east it is undeniable that the love of money has led them into lax uses of their licensing function, which have been detrimental to the profession and the public. Of course, the abolition of the mere local character of the licence to practise has added greatly to its money value. A licence that includes the empire is more valuable than one that covers only four Scottish counties, and still more so than one that applied only to as much of Edinburgh as was included within the walls of the ancient city. The corporation whose powers were before 1858 so limited, and by the Act of 1858 were so enlarged, has naturally displayed the greatest tendency to excess in the money-making use of its diplomas. The late Professor SYME estimated that in one year after the passing of the Act this corporation made £10,000 by the easy gift of its lowest diploma. It is clear the abolition of the local jurisdiction of diplomas ought to have been accompanied with a reduction in the number of diploma-granting bodies, with securities for those that were left being conducted with equal severity, and under no temptation to make money by the exercise of this most responsible function. The Act of 1858 took no such securities. It left nineteen bodies to confer licences at their "own sweet will," and it is now well known that if one body has a strait gate, others have very elastic portals, that admit the entrant with what may seem a little pleasant pressure, but without friction or contusion. We are speaking now only of the lowest diplomas—not of higher qualifications—such as degrees, fellowships, &c., which will have to be considered by-and-by; but of the nineteen portals which it has been found simply impossible to control under the Act of 1858, simply because they were nineteen, and because the supervising Council of Education was practically a Council made up of the nineteen bodies to be supervised.

The terms of the Commission include a full inquiry into the nature and action of the Medical Council, its constitution, functions, powers, and procedure, its relation to the various bodies and to the medical profession. A Medical Council could not well be composed of members of more obvious influence and respectability than the present Council. It is composed chiefly of men in the consulting ranks of practice, and holding high places in the various nineteen bodies represented in the Council. But the representation is most peculiar. The Irish Apothecary Society, which is essentially a trading company, and the Faculty of Physicians and Surgeons of Glasgow, which before 1858 used to give licences to practise in four counties only, have each a representative, whereas the Edinburgh University, with over 3000 students, of whom 1600 are medical students, has only half a representative—that is to say, the University of Aberdeen and that of Edinburgh have one representative between them. Even if the representation of bodies were more proportionate to their professional value and importance, it is a grievous fault of the Medical Council that it consists so predominantly of bodies pecuniarily interested in the retention of half diplomas and of their own traditional individuality. The consequence of this feature in the constitution of the Council is that all changes and improvements suggested in medical education or in examinations for diplomas are viewed from nineteen points of view, and generally frustrated by the conflicting opinions and interests of the different bodies with which ultimately the decision rests. This brings us to another fatal defect in the Council. It has no authority. Its conclusions take the form only of Recommendations, and are not binding on the bodies. The Commissioners may easily satisfy themselves that many of the most momentous Recommendations of the Council remain unfulfilled and inoperative for want of this element of authority in it. What is worse, because more significant of the faulty constitution, is the fact that the Council has always shown an unwillingness to be made a responsible body. It meets at a great cost. It numbers twenty-three or twenty-four members of the highest personal and professional position. Yet it is always reviewing and repeating its debates and its conclusions, and always being reminded that they are not operative. It is afraid of the bodies it represents, or acts as if it were so. It has, further, ever been regarded as a grave defect of the Council that it contains no direct representatives of the profession. Considering that it exists to regulate the education and the examination of general practitioners, considering that the Council is maintained by what is to all intents and purposes a tax on general practitioners, that one of its great functions is to keep a correct Register of the profession, and, finally, that it has the judicial power of removing practitioners from the Medical Register for "infamous conduct in a professional respect," it seems most unreasonable that the profession, apart from its mere corporations, should be unrepresented. There was an understanding at the time of the passing of the Medical Act that the Crown representatives would be chosen from the ranks of the profession; but as a rule they have been prominent members of the Corporations already over-represented. It is not necessary to deny that the Council is composed of most respectable members of the profession, nor even that it has done a certain amount of good. What we are concerned to show is, that considering the personal character of its members, it should have done much more good than it has done. It has added enormously to the severity of examinations without having added correspondingly to the simplicity of the examining system or the efficiency of the medical schools.

Annotations.

"Ne quid nimis."

EARL DERBY ON HOSPITALS AND PROVIDENT DISPENSARIES.

In his speech at the festival dinner in aid of the Middlesex Hospital on the 13th inst., the Earl of Derby made some very judicious remarks. He pointed out that large hospitals were absolutely necessary for the treatment of the many sick whose homes were incompatible with proper care of the sick; whilst strongly expressing the hope that the country would in time be covered with provident dispensaries, so that people may contribute to their own support and recovery when they are ill, he justly remarked that no dispensary system, however perfect, would meet the requirements of those grave and dangerous cases which can only be dealt with in institutions where skill and attention were ever at hand. Provident dispensaries would relieve the over-burdened out-patient departments of our hospitals, and that would be a great gain; but they could never replace the advantages derived from hospital wards. Besides, hospitals are "schools of medicine, by which the wealthy profit quite as much as the poor and working classes. A rich man can always command the best medical skill, but the physician or surgeon who attends him would be greatly wanting in skill and efficiency if he had not acquired experience in the great hospitals. Again, in rural districts you have, happily, frequent and kindly intercourse between the rich and the poor. If the labourer is ill, the squire, his neighbour, does what he can for him. Here there is a different state of things. No one knows who his neighbour is in a vast city like London. But if you are to have no intercommunion between the rich and the poor, you will have the one class selfish and morally low, the other hostile and revolutionary. How are they to be brought together? Of all kinds of help that can be given to the poor in a place like London there is none so free from dangerous abuse as that offered by hospitals. However undeserving a man may be, you do not want him to die of disease; and, as regards imposture, a man may for money simulate disease, but unless he is half a maniac he will not do so to get into a hospital. Therefore a man who gives his money to one of these great London hospitals may fairly be described as not only benevolent but beneficent." These words of appreciation for the good work done by hospitals, coming from one who is not prone to form hasty judgments, must be full of encouragement to those who devote much of their time and energy to the development of these institutions, the maintenance of which, in a proper state of efficiency, is becoming every year a matter of increasing difficulty.

THE ANATOMY OF GHOSTS.

The hypothesis offered by Mr. Francis Galton in explanation of the phenomenon of "mental images"—namely, that the mind builds up the mental picture on the foundation and with the materials furnished by external objects, as "children and sick people get faces and forms from paper-hangings and curtains"; the eye seeing little, and the mind supplying the rest of the idea, is not new, though it may be true. Leonardo da Vinci, the great painter, showed his appreciation of this method in his direction "To compose a Battle Piece"—namely, to stare at a smoked and daubed wall until the confusion suggests the desired conception. And the same explanation has been submitted by all writers before and since the time and speculations of the author of "Demonology and Witchcraft." The chief merit of Mr. Galton's contribution to the literature of this subject is the admirable summary he has given of the known facts with regard to the association of sound and colour with form. The manner of this association is unimportant. It is the result with which we have to deal. Meanwhile, none of the theories or hypotheses raised by the expounders of hallucinations are entirely satisfactory, because they either do not recognise, or they practically disregard, some of the most potent factors in a class of experiences which has long constituted the opprobrium of introspective science. A man sees a ghost; to him it is as *real* as anything else he sees, and it is not to be explained away or accounted for by any reasonable process of argument. A reference to the power of the imagination will not satisfy the subject or victim of hallucinations. If he be weak-minded he will insensibly come to believe in their reality; and, even if he be strong-minded, they will worry and annoy, perhaps mislead, him. It is, therefore, a matter of moment that what we may designate the anatomy of ghosts should be scientifically investigated. By way of suggestion, we venture to throw out the following hints. Every personality or consciousness has surrounding it an atmosphere of its own, with clouds of hazy impressions and nebulous thoughts and all the apparatus necessary for mental spectres, from which the mind receives back more or less accurate, or distorted, reflections of its own ideas. In addition to this proximate source of "mental images"—which are external to the observer, and yet the mere reflection of his own mind—there is the remote, or true external, which is seen *through* the atmosphere, the surroundings or environment, of the mind itself. Such external objects as have a life and individuality of their own, have also *their* environments and systems of reflexes. So that what we see with the "mind's eye," when thinking of another person, is the aggregate or mean—or resultant—of our previous images of him. These images are made up of what we have in past times seen through our environment, and had reflected back from it, together with whatever impressions may now reach us through the environment of the person modified by his reflexes, and through our environment modified by the disturbing influences which it also must exercise on the impression we seem to receive. In short, every living object which is external is seen through two environments, and the image we form in our mind is modified by two sets of reflections. There is no such possibility as seeing things as they *are*. We see things as they are presented by the external, and as we think of them. It is at once obvious how many sources of fallacy there are, and how many possible ways of introducing new images, or of changing those which are transmitted, actually exist. A ghost may therefore be formed of materials cast up in either, or all, of four processes in the seemingly single and instantaneous mental act of observation. 1. We perceive an external object which suggests a thought of some person. 2. We seem to see the object in the form in which it has been presented to us on previous occasions and associated with remembered characteristics of colour and sound. Form, colour, sound, and even odour, or touch, stand on precisely the same footing as regards their mental associations, and either may play the part of a first agent or keynote in producing the impression. 3. When we see a form or colour, hear a sound, smell an odour, feel a touch which has been associated in our minds with the form of an absent friend we may be, as it were, visited by his ghost, or, in other words, the fragment of real external will call up, seemingly around it, but actually in our minds, the complementary properties of the object. 4. Receiving the picture projected from without, adorned by the memory of previous impressions of its subject, we still further develop it, adding the impression of our own present reflections, and probably finishing the picture according to the mood of the moment, making the "mental image" grave or gay, and adapting it to the supposed associations of the individual as we think of him under the influence of any fear or fancy our minds may cherish with regard to his condition or circumstances. The whole of this building up or fashioning of ghosts may be comprehended within Mr. Galton's hypothesis, or it may not. We do not quite gather the fact from his lecture. It is easy to say that "the eye sees little and the mind supplies the rest of the idea"; but this would not be the whole truth, because the mind takes the material for its construction of the ghost organism, not wholly or even in great part from its own inner chambers of imagery, but from the physical record of impressions which, if, at the moment, past, were originally received and not conceived. We should be glad if the view actually entertained by Mr. Francis Galton could be more definitively communicated. The subject is one of great practical interest to the sick, and to many who seem, and believe themselves to be, sound of mind and body, to wit, the whole class of "spiritualists" or believers in spiritism.

MEDICAL REFORM AT BRADFORD.

THE enemies of medical reform take pleasure in misrepresenting the aims of its friends. They say that the medical profession has no higher wishes than to get larger fees and more exclusive privileges. The great memorial of the profession in 1869, signed by nearly 10,000 practitioners, refuted this calumny. The following recommendations, arrived at at a meeting of the profession of Bradford and neighbourhood, will serve as another proof that, however medical men may be bent on maintaining the interests and dignity of the profession, it is their conviction that these are to be maintained chiefly by thoroughgoing measures for upholding and testing education, medical and general. The following are the recommendations agreed to by the meeting.

1st Recommendation: "That this meeting recommends a one-portal system of examination and admission to the medical profession for the whole kingdom, with various examining stations. The examiners should be appointed by the State; say nineteen from the present examining bodies, six by the State, and six by the general body of the profession. That the qualification given shall be an all-round one. Corporations still to give degrees when called upon." 2nd Recommendation: "That Preliminary Examination be high, embracing as essentials, Latin (so as to read easy authors), Greek (so as to read the alphabet and look out roots in the dictionary). One foreign modern language also to be necessary. The above to be passed before the commencement of any medical studies whatever." 3rd Recommendation: "Before commencing his more exclusively medical studies, the student should pass a second examination in physics, botany, natural history, and chemistry. A pupilage of at least twelve months with a qualified medical practitioner should also be required before obtaining his diploma or qualification to practise." 4th Recommendation: "Medical curriculum to extend over three years after the above examinations have been passed." 5th Recommendation: "Only duly qualified persons to practise as assistants."

EUCALYPTUS GLOBULUS AS AN ANTISEPTIC.

THE last meeting of the Clinical Society was of considerable interest to surgeons, and especially to those who practise antiseptic surgery as taught by Professor Lister. The subject of carbolic intoxication was raised by Mr. Pearce Gould, who asserted that he had had a fatal result from it, and Mr. Lister assented to his views, so that we may speak with confidence of their substantial truth. For the first time exact minute pathological changes were identified with the toxic effects of the acid in man, and although the observation needs corroboration, it yet throws light upon much that has been hitherto obscure. We are glad to observe that there was no attempt made to make this case a text for an attack upon any "system," or even upon carbolic acid itself. And we are particularly glad of this because Professor Lister was better able to make an important statement, which was a most welcome sequel to such a case. He frankly recognised the fact that there are some persons injuriously affected by carbolic acid, and that while many substitutes for it—thymol, salicylic acid, sulphurous acid, and so forth,—have been tried at various times, they have all been abandoned on account of drawbacks, even more serious than that attaching to phenol. His trials, however, of the oil of Eucalyptus globulus have shown him that while entirely free from toxic or locally irritant effects, it is a perfectly trustworthy antiseptic. Where, therefore, we have reason to fear carbolic absorption or where the carbolised gauze causes toxic effects, the oil of eucalyptus may be used without in any way imperilling the results of so-called asepticism. But the oil has its own drawbacks: one is its insolubility in water, and another the rapidity with which it evaporates from most of its solutions. An oily solution would very quickly become quite inert as an antiseptic for this reason; resin holds it in combination more firmly, but dammar gum, such as is used in mounting microscopical preparations, is better still, and has been chosen by Professor Lister as the medium for its employment. Gauze impregnated with this mixture and paraffin has been prepared, and is in appearance and feel exactly like carbolised gauze, but unlike it in having an agreeable aromatic odour. Obviously there are other details yet to be worked out, and experience warrants the hope that Professor Lister may soon be able to announce that he has overcome the difficulties they present, and that this new and safe antiseptic can be used as generally and as easily as carbolic acid. In its cost it probably will never rival the acid, nor is it certain that it will supersede it entirely; indeed, Mr. Lister did not for a moment hold out any such idea. Carbolic acid has been well tried as an antiseptic agent, and what we are really in need of is some guidance as to the circumstances in which it is liable to act injuriously. However hopeful we may be at the discovery of an antiseptic agent which is safer than those we now possess, we should yet gladly welcome any additions to our knowledge as to the true meaning or cause of these so-called "special susceptibilities," "idiosyncrasies," and the like, which make the means of life to one man the very cause of illness or death in another. Perhaps it is hardly to be hoped that a perfect antiseptic agent devoid of toxic properties for the human body will ever be found; for there are some, if not many, fundamental conditions alike required for the highest and the lowest forms of life. The laws governing the development of the bacteria and similar minute organisms, which are roughly classed together as germs, are probably the same, or at least closely allied to those ruling the growth of the cellular constituents of our own frames. And surprise ought not to be so much excited by the occasional occurrence of toxic symptoms when antiseptic surgery is practised, as by the more striking fact, constantly observed, that these agents can be used with entire success to destroy and prevent the development of these "germs" without destroying or even affecting injuriously the vital processes so akin to them. It would be an easy matter to speak with enthusiasm of this statement of Mr. Lister, and to prophesy the attainment of perfection in the antiseptic treatment of wounds, now that he has provided us with an agent that may be called safe and certain. All such enthusiasm would be out of place, however; the new preparation must be patiently tried; and although it is only right to entertain the hope that it will be found of extreme value, it is demanded in the interest of science that any expression of opinion as to its merits should be suspended until the facts are fully before us. It is not, however, too early to draw attention to the fact that Mr. Lister has afforded us another example of his devotion to science. His name has for years been associated with the use of carbolic acid in the treatment of wounds, and with it he has accomplished remarkable results; but he has kept his mind so open to its defects, that, being the most earnest in the search, he is the first to herald the discovery of a substitute for it. Would that all of us who have some pet theory or practice could learn this lesson!

BRIGADE SURGEON E. L. LUNDY, A.M.D.

THE Indian papers report the death of Brigade Surgeon Lundy, at Allahabad, on the 19th of April, under very painful circumstances. It appears that a few days previously he returned from Deolali to settle some matters which had occasioned him a good deal of trouble. On the morning of the 21st he went to the hospital and obtained three or four drachms of poison, the nature of which is not specified in the account which has reached us. He then returned to his hotel, where he was shortly afterwards found in his room breathing heavily, and quite insensible. Medical assistance was at once obtained, but he died in a few minutes afterwards. The verdict of the coroner's inquest was that he died by poison taken when in an unsound state of mind. Mr. Lundy was an officer of long and distinguished service. He served throughout the Crimean War, and was present at the battles of the Alma and Balaklava, and at the capture of Sebastopol. He went through the Persian Campaign of 1857 with the 64th Regiment, and was in the Indian Mutiny with Havelock's column as well as at the defence of the Alum Bagh, the defeat of the Gwalior Mutineers at Cawnpore, and several other minor engagements. Brigade Surgeon Lundy was much esteemed as an able, efficient, and zealous officer. We regret to add that he has left a wife and family.

THE NEW MEDICAL CORONERSHIP.

THE triumphant assertion once more of the preference in the metropolis for a medical coroner is a subject for great congratulation. The triumph indeed was so complete that the only danger before Dr. Thomas is that of thinking too lightly of an office which has come to him so easily. We do not think that Dr. Thomas is likely to make such a mistake, or to undertake the duties devolving upon him with an inadequate sense of their responsibility; but there can be no harm, when the desired result has been so successfully achieved, in stating what we expect from the election of a medical coroner. We expect, above all things, that the work he has to do will be so done as to bear the criticism of the medical profession. Every week brings us reports and complaints of the perfectly useless and formal way in which inquests are conducted without eliciting any data for an intelligent opinion as to the cause of death. We have a right to expect from a coroner of Dr. Thomas's character, and elected as he has been, that inquests shall be so conducted as to carry the respect of those best able to judge. Where an inquest can be dispensed with, for the sake of friends and human feelings, by all means let it be dispensed with; but when it cannot, let the evidence taken be of the best. It often lies entirely in the discretion of a coroner to select persons to make post-mortem examinations, on the revelations of which the accuracy of the conclusions of the jury entirely depends. He may leave this selection to a subordinate, whose choice may turn upon very irrelevant considerations. This is a duty which should be discharged not by the officer of the coroner, but by himself. On other occasions, too, even medical coroners, for the sake of a little passing popularity, have dispensed with medical evidence altogether, when without it an inquest was an unmeaning farce. We trust Dr. Thomas to avoid such errors. He owes his election to the intelligent preference of the public, guided by the profession, for a medical coroner, and we look to him to hold high the reputation of a medical coronership for dignity and usefulness.

ALLEGED INHUMANITY AT HAWARDEN.

WE have read with great pain the newspaper report of the Government inquiry into the death of the children of William Francis, of Stryt Issa. It is much to be regretted that Dr. Moffatt did not see the cases sooner, but it seems to us that of all the officials concerned he was perhaps the least to be blamed. It is a strange illustration—to which under less "urgent" circumstances we should have called the attention of the Premier himself—of the fact that in this highly Christian country sanitary law is in such a state that months after a most unsatisfactory report on the state of a house a child may die in it unattended by any medical man, be found dead in bed with another living child, two others ill crouching at the fire, all affected with scarlet fever, and the three be removed to the workhouse by a relieving officer in an open butcher's cart with twenty-three degrees of frost in the air. He would be further interested to learn that they were then received into a reception ward in which the tea and the barley-water both froze in the morning, and that they were allowed to remain unseen by the medical man for three days for want of a special message from the master. The whole story is most distressing. Although we cannot acquit the medical man of responsibility, we think it is very much qualified by his intimation to the master that unless there was some urgent necessity he would be unable to pay his usual visit on the Monday. The Local Government Board, in their distribution of censure, have properly not omitted to censure the Board of Guardians for allowing Francis's cottage to be inhabited after the bad reports made to them by their officer, and they should have added a special censure for having no better means of conveying scarlet fever cases than a butcher's open cart.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

THE extent of the forthcoming Exhibition shows a tendency to grow steadily, and the proportions which it bids fair to assume will not be far short of those minor International Exhibitions which followed the great show of 1862. The Horticultural Society have placed the whole of the arcades of their garden, which will accommodate a continuous line of exhibits over 2000 feet in extent, at the disposal of the Executive Committee. The Science and Art Department have given up about 200 feet of the Western Picture Gallery, which will serve as an excellent place for the exhibition of microscopes, surgical instruments, and other kinds of delicate apparatus. In addition there are four rooms under the Albert Hall which will be devoted to exhibition purposes, and one of which it is proposed to fit up as a hospital ward, to contain every variety of bed and ward appliance. Besides the space already mentioned there are the glazed quadrant arcades, so that the total space at the disposal of the Exhibition Committee will be not far short of 3000 feet of frontage. This ample amount of space will ensure to every exhibitor a good place for the display of articles, and there is no fear that any will be at serious disadvantage in this respect. The Committee have received over 400 applications for space, but they are still, we believe, ready to receive further applications. The galleries of the Western Picture Gallery will afford a great amount of additional wall space, and it is hoped that the authorities in the various watering-places and health resorts will take advantage of this for displaying pictures, &c., illustrative of the localities in which they are interested.

CADAVERIC ALKALOIDS.

MM. BROUARDEL and BOUTMY have communicated to the Académie des Sciences some further observations on the alkaloids developed in the animal body during decomposition —alkaloids which M. Selmi has termed *ptomaines*. According to Bouley and Lussana these substances may be developed not only after death but during life. It is still uncertain whether they are formed by simple chemical action or by the influence of minute organisms. The latter appear concurrently, but they may possibly be merely an indication that these alkaloids furnish a favourable soil for the development of this or that organism. The special object of M. Brouardel's researches was the discovery of means by which these substances may be distinguished from vegetable alkaloids. It is probable that the two have been sometimes confounded, and that this confusion has led to grave errors in medico-legal investigations. It was so in a recent case in Italy, where an expert believed that he had discovered, in the body of a deceased General, evidence of delphinine; the reactions supposed to be proof of it were, however, certainly due to one of these cadaveric alkaloids. The most effective method of distinguishing between the vegetable and the animal alkaloids is by making a complete examination of the chemical and physiological properties of the suspected substance; and if any one of these proper to a vegetable alkaloid is absent, it is probable that the substance is not this alkaloid, but a ptomaine which resembles it. This method is, however, tedious and difficult, and is only practicable when a considerable quantity of the suspected material is available. A more convenient method of distinguishing them is by the employment of ferricyanide of potassium. This substance is unaffected by the pure organic bases of the laboratory, or those extracted from the body of a person who is known to have been poisoned. The cadaveric alkaloids, however, instantly transform it into ferricyanide, and it becomes capable of forming prussian blue with salts of iron. The iodomercurate of potash gives similar reactions with both classes of substances, but the ferricyanide enables them to be distinguished. A few drops of a solution of the sulphate of the alkaloid are added to a solution of some of this salt in a watch-glass, and then a drop of a neutral solution of iron determines the formation of prussian blue if the base is a ptomaine, and not if it is a vegetable alkaloid. Unfortunately there are two important exceptions to this test: morphia produces a similar effect; and so also does veratrine, but in a much less degree.

RESULTS OF THE RECENT CENSUS.

IT is difficult to restrain a feeling of impatience for the issue of an official instalment of some of the results of the recent census. For weeks past the papers have teemed with paragraphs containing census figures of local origin, a large proportion of which is probably trustworthy within certain limits, while so many have been obviously misleading, as regards towns, on account of the numerous and conflicting boundaries used for municipal, parliamentary, or other purposes, that it is dangerous to formulate any conclusions on such information. Following previous precedent we may expect a preliminary census report, giving the unrevised figures for the whole of England and Wales, before the end of June. There will be no reasonable ground for complaint at this delay in the preparation of a return relating to a population little short of 26,000,000 of persons. In the meantime, however, there is a manifest inconvenience in having to wait so long for even the unrevised populations of the twenty large English towns dealt with in the Registrar-General's Weekly Return. It is noted in the last of these returns that new estimates of population, based upon the recently enumerated numbers, will shortly be substituted for the estimates still in use, which are mainly calculated upon the rate of increase that prevailed in the several towns during the decade 1861–70. It is at least undesirable that the Registrar-General should any longer continue to publish in his Weekly Return population estimates which have been proved erroneous, and rates of mortality based upon those estimates which differ widely from those supplied by local medical officers of health, who have now substituted the enumerated numbers for the incorrect estimates. Assuming the approximate accuracy of many of the population numbers locally issued, it appears certain that the population of most of our large towns was considerably over-estimated by the Registrar-General's method; in other words, the rate of increase of population in the last decade has been generally smaller than in the preceding decade. Especially were the populations of Leicester, Manchester, Salford, Bradford, and Sheffield over-estimated. These over-estimates are still used in the Registrar-General's Weekly Return, and the rates of mortality in several of the towns are thus understated to the extent of more than 2 per 1000. It may be hoped that this anomaly will soon disappear. If the locally published figures are to be trusted, the population of the city of Manchester actually declined to the extent of nearly 10,000, or about 3 per cent., during the last decade; this decrease, however, was to a great extent balanced by an increase of more than 50,000, or 41 per cent., in Salford, and by a still larger increase in other directions outside the municipal boundaries of the city.

AN INTELLIGENT JURY.

A case which lately came before Mr. H. C. Yates, the coroner for Sandbach, is rightly stigmatised by the local journals as "extraordinary," albeit that the facts are of a very ordinary kind. On the night of April 9th a Mrs. Froggatt, aged eighty-two, having been undressed by her servant in the presence of the servant's little daughter, bolted her bedroom door on the inside and retired to bed. The next morning she did not ring as usual, and when called failed to answer. The servant, in the presence of her daughter and another woman, then broke in a panel of the door, drew back the bolt, entered the room, and found Mrs. Froggatt dead. The medical man who was called in testified, in effect, that deceased had probably been convulsed at the moment of death, and searching for the cause he had found a set of twelve false teeth, which she had forgotten to remove when she went to bed, jammed into the lower part of the pharynx, and obstructing the larynx. The medical opinion was that death had resulted from suffocation due to the impaction of the false teeth. Notwithstanding this a post-mortem examination was ordered, and a medical gentleman other than the one who was called to the deceased was requested to make it. The post-mortem afforded evidence of death from suffocation, and an analysis of the contents of the stomach showed that it did not contain any poison. Not a particle of the evidence given at the inquest was contradicted, and to all ordinary minds the cause of death must have seemed certain. The coroner's jury, however, "drest in a little brief authority," thought fit to return the following verdict after a deliberation of half an hour's duration:—"That the deceased died from suffocation, but that there has not been sufficient evidence brought before them to show how such suffocation was caused. The jury wish to add that they consider Dr. Davies was guilty of an error in judgment in having taken the teeth from the deceased's throat without proper authority"! A coroner's jury seldom returns such a fantastic verdict as that arrived at by the twelve good men and true of Sandbach. We would point out, however, that the only logical sequence of such a verdict in the face of such apparently conclusive evidence would be a prosecution of all the witnesses for perjury.

AN AUTOMATIC THERMOMETER.

According to an announcement of the *Scientific American*, clinical thermometry is to be very much simplified. Automatic registration has been long employed with success in many meteorological investigations, and also in the physiological laboratory, but scarcely at all in clinical work. Dr. Adams of Colorado Springs has, however, invented a "thermograph," which is said to be capable of registering the variations of the temperature of the human body. The apparatus appears from the description to be not a little complex both in principle and in construction. First the heat is transformed into motion, the motion into electrical resistance, and the electricity is transformed, *viâ* magnetism, into registrable motion, the variations in which are thus indications of the variations in the electrical resistance, and therefore of the initial heat. The essential principle is that of using the variations in electrical resistance as the indications of a variation in another form of force—a further application of the pregnant discoveries of which the microphone was the first-fruits. Dr. Adams's instrument is said to consist first of a metallic thermometer—a spiral spring made of two springs of brass and steel, on the principle of the compensatory balance-wheel of a watch. The effect of a slight elevation of temperature is to cause the spring to twist, and a knob at its extremity to compress a powder made of plumbago, gas-carbon, and silver, which is contained within a vulcanite tube. Through this powder the electrical current is passed, and the variations in its force, which depend upon the varying compression of the powder, affect an ingenious electro-magnetic mechanism which traces a line on a moving surface, and the curves thus traced indicate the variations in the temperature of the body.

THE CRÉCHE.

Every now and again we hear of a paucity of useful work for women. It is essentially woman's work to nurse babies, and those who are not *above* such feminine service may do incalculable good by establishing créches for the safe and kindly custody of the children of the labouring poor while their mothers are engaged in their daily duties as bread-winners. We note with satisfaction that this laudable enterprise is extending, and that it is beginning to receive the support it deserves, alike from women of the wealthier classes and those for whose aid and convenience it has been inaugurated. The sufferings of infants which are either dragged or tossed about by their mothers during a hard day's toil, or left in the charge of children too young, and physically unable, to take proper care of them, are terrible and needless. Many are crippled for life, or contract incurable diseases, under this neglect or mismanagement. The créche is a home where mothers of the working classes can leave their babies on their way to work, and fetch them at night. The benevolent persons maintaining establishments of this description provide proper nurses and appliances for the care of the infants so deposited during the day. A small fee is charged, and this deprives the institution of a charitable character, which would prove ruinous to the prospect of success. We feel, and urge, the duty of supporting these créches by every means in our power.

DR. BORLAND OF KILMARNOCK.

Fifty years of medical work in and about Kilmarnock were crowned and celebrated on the 29th of April most worthily. The inhabitants assembled at a good old-fashioned Scotch supper, and made sure of the presence of Dr. Borland, the hero of the occasion. The chair was most ably and gracefully filled by Provost Sturrock, and, after supper, began such a flow of good feeling and good speech as has not often been exceeded. We do not use the words of form when we express our regret that we cannot find room for the eloquent speeches, especially those of the Provost and of Dr. Borland. The remarks of the former were backed by the presentation to Dr. Borland of £500, and a silver salver, with the following inscription: "Presented to John Borland, M.D., with a cheque for £500, and a gold brooch for Mrs. Borland, on the occasion of his jubilee, as a medical practitioner in Kilmarnock, in recognition of the invaluable services rendered to his native town during the past half century.—Kilmarnock, April 29th, 1881."

BRIGHT'S DISEASE AT BERBICE.

Dr. Grieve, the medical superintendent of the Berbice lunatic asylum, publishes a journal composed and printed at the asylum, which among other matters contains an article on the prevalence of Bright's disease in the colony as indicated by the asylum records. It would appear from the latest 100 cadaveric sections made in the asylum that advanced degeneration of the kidneys sufficient to account for death, or disease in a less advanced stage, but still distinct and unmistakable, was seen in 86 cases, whilst only in 14 bodies were the kidneys found to be free from this change, so that 80 per cent. of those who died and whose bodies were examined had been subject to Bright's disease. It is noted that this great extension of the malady is not confined to the asylum, because a few years ago Dr. Hackett undertook an examination of the urine of every patient under treatment at the time in the Berbice Colonial Hospital, and found albumen in the urine of nearly 90 per cent. of the cases. It is suggested that the anæmia so frequently seen in the colony and much of the chronic diarrhœa are concomitants of Bright's disease; and, further, to the prevalence of this disease the high rate of mortality which obtains in the colony is due.

IRISH UNION HOSPITALS FOR PURPOSES OF CLINICAL STUDY.

THE following memorial raises an important question, and directs attention to a great field of hospital study, which has not been sufficiently regarded either in Ireland or elsewhere. It is too readily concluded that the clinical study of disease is only to be carried on in hospitals formally attached to medical schools. We may revert shortly to this subject. Meantime we place the memorial on record as creditable to the physicians and surgeons of the union hospitals of Ireland.

"*Memorial of the undersigned Physicians and Surgeons to Union Hospitals to the Senate of the Royal University, respectfully sheweth,*—

"That clinical or bedside training is universally admitted to be of the first importance in the education of medical students. That a mere fraction of the resources available for such instruction is now at the disposal of such students. That during the year 1877, 111,134 patients labouring under all forms of sickness were treated in these various union hospitals, which are provided with every possible requisite for the treatment of disease, while during the same time not more than 16,000 patients were treated in those hospitals of Dublin, Belfast, Cork, and Galway, which have between them the monopoly of clinical instruction. That no system of concursus regulates the appointments to the medical staffs of those clinical hospitals in the four towns last referred to, and that no ground therefore exists for alleging such a difference in the attainments of the respective staffs as would furnish a plea for excluding provincial men from all share in clinical teaching. That the results of the present system of monopoly are such as might have been anticipated, and that the serious attention of the General Medical Council was long ago directed to those glaring defects in the practical training of medical students. That in the year 1877, chiefly at the instance of Sir James Paget, the Council resolved to recommend that one year of the medical curriculum should be spent by each student at a union or other provincial hospital. That local interests and the deficient powers of that Council have heretofore prevented this enlightened recommendation being given effect to. That having every confidence that your body will not allow such mere local interests to any longer oppose obstacles, and looking with every confidence to your University placing itself in the van of progress, the undersigned respectfully memorialise you to enforce this recommendation of the governing body of the medical profession."

VOLUNTEER SURGEONS.

WE observe with satisfaction that Mr. Childers has announced his intention of putting the Surgeons of Volunteer Corps on the same footing with regard to retirement as Militia Surgeons not on the departmental list. They will be entitled to retain their rank on retirement after fifteen years' service, and after twenty years' service will receive a step of honorary rank if duly recommended for it.

CHARLES MURCHISON MEMORIAL CLINICAL SCHOLARSHIP.

THE legal deed in connexion with this memorial is now being considered by the University of Edinburgh and the Royal College of Physicians of London, the two bodies with whom will rest, alternately, the award of this Scholarship. Another anonymous donation of £100 has been sent through Mr. T. H. Hills, and this, with some recent subscriptions, the balance of the St. Thomas's Hospital Fund (for the bust), and the interest on deposit account, brings up the total amount, after payment of expenses, to the sum of £1000. When the trust deed is completed this money will be handed over to the College of Physicians. It is hoped that the first award of the Scholarship may take place in London in April, 1882.

BOARDS OF GUARDIANS are, it is well known, not always just, and but seldom indeed generous, in their treatment of union medical officers. It is therefore with the more satisfaction that we note a graceful act on the part of the guardians of Holbeach—one the publication of which may, let us hope, quicken in other parochial authorities the sense of appreciation of the services of gentlemen whom they appoint to watch over the medical interests of the poor. Recently a young woman was received into the Holbeach workhouse infirmary suffering from an ovarian tumour. This was successfully removed by Mr. Harper, the medical officer; and the extra anxiety and attention necessarily entailed by the treatment of this case, as compared with those constituting the ordinary work of the infirmary, have been acknowledged by the guardians by the award to Mr. Harper of a fee of ten guineas.

THE BUILDER, in an article entitled "Traits of the Earl of Beaconsfield," recalls the fact that when Mr. Disraeli delivered his maiden speech in the House of Commons, "Thomas Wakley, the popular and eloquent member for Finsbury, of that time, remarked to me a day or two afterwards, in respect to it, 'That young man told us that we should listen to him some day—and I fully believe it—and that the country will do so also.'" This is strictly true. The same expression of opinion was made to Sir Robert Peel.

MR. A. B. JAY, the sculptor to whom was entrusted the modeling of the statue of Harvey, which is to be unveiled at Folkestone in August next, will be pleased to exhibit that statue, and one of Mr. Gladstone, which he has recently completed for the East-end of London, to members of the medical profession, upon presentation of their cards at the Studio, No. 8, the Avenue, 76, Fulham-road, South Kensington, on Tuesday or Wednesday next, the 24th and 25th instant.

MR. E. H. BENNETT, Professor of Surgery in the University of Dublin; Mr. Baker; and Mr. Meldon, Surgeon to Jervis-street Hospital, are candidates for a seat on the Council of the Royal College of Surgeons in Ireland.

AT the meeting of the Royal College of Physicians on the 16th inst., Dr. Burdon Sanderson was appointed Baly Medalist for 1881.

DR. ALLEN THOMSON has been elected one of the trustees of the Hunterian collection of the Royal College of Surgeons, in the place of the late Dr. Sharpey.

DR. BARCLAY will deliver the Harveian Oration at the Royal College of Physicians on Saturday, June 18th.

We gladly direct attention to the morning performance to be given at the Gaiety Theatre on Monday, the 30th inst., in aid of the funds of the Hospital for Hip Disease in Children, Queen-square and Bournemouth. The programme of the entertainment is of an attractive character, and the result, we trust, will be a large accession to the resources of an institution the value of which to the poor little sufferers from morbus coxæ is almost incalculable.

Drs. J. T. Banks, Peter Redfern, F. R. Cruise, W. A. M'Keown, and A. Macalister have been appointed to seats on the Senate of the Royal University of Ireland.

The Society of Medical Practitioners of St. Petersburg, at their meeting of May 2nd, decided to admit medical women to the membership of the Society.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Derby (*Urban*).—Mr. Iliffe reports for this borough during 1880, among an estimated population of 80,385, a birth-rate of 37·9 per 1000 inhabitants, and a death-rate of 20·0. But the sanitary condition of Derby does not appear to be so good as might have been anticipated in so important a town, as Mr. Iliffe finds it necessary to draw the attention of the Sanitary Authority *again* to the necessity of the removal of cesspools in crowded areas, and to the desirability of paving courts and alleys, which in many places, he says, are in a disgraceful state and positively injurious to health by allowing filth to accumulate on the surface of the ground without the means of being disposed of except by exhalation and soakage into the subsoil. The most interesting part of the report is the account given of a year's working of the Derby Improvement Act, 1879, which imposes a compulsory notification of infectious diseases to the Sanitary Authority upon the inhabitants of the borough. Mr. Iliffe believes that this provision, which on the whole appears to have been carried out without serious opposition, has materially contributed towards diminishing the number of illnesses, as well as the number of deaths from fever, &c. It has certainly been of practical value to him, he says, "in bringing to light many insanitary conditions existing in houses and areas, which otherwise might have been overlooked until further disease and death had taken place; and it has enabled him to prevent the spread of infection in many localities by adopting means of isolation, disinfection, &c., and also by keeping children likely to spread disease from attending school and other public resorts, a danger that was formerly only too common. It has been the cause of affording your medical officer the means of frequently tracing the cause of disease, and the origin of the various attacks, and it may be that in the future it may contribute materially towards saving the town from widespread epidemics." The action of the medical officer and his staff upon the information received from this compulsory notification appears to have been received by the people affected by it, as a rule, with "thankfulness and gratitude," and no opposition was experienced from the general public. The cases of infectious disease notified under the compulsory notification clauses of the Improvement Act were 1295, the greater number being measles. Derby is deficient in sanitary hospital accommodation; had it been otherwise, Mr. Iliffe would, doubtless, have been able to report still more favourably of the beneficial operation of the clauses.

Newbiggin-by-Sea, Urban (*Northumberland*).—Dr. J. C. Reid, assuming that the population has been virtually stationary since 1871, gives the death-rate of this urban district in 1880 as 18·96. He writes favourably of the health condition of the town during that year, and expresses a hope that the annual rate of mortality will be reduced to 15·0 per 1000 population, which, he holds, would be the normal mortality of the place.

Wareham and Isle of Purbeck, Urban (*Dorchester*).—Dr. W. W. Stainthorpe reports for this sanitary district, during 1880, a death-rate of 14·2 per 1000 population. He describes in detail his proceedings in the execution of his duties, and suggests, in view of the frequency with which the medical man is not called in in illnesss, the formation of medical clubs among the labouring classes after the manner of the Suffolk County Medical Club, by means of which a labouring man would be able to obtain the services of a doctor for himself, his wife, and family for a small annual sum. He would have it a rule of such clubs that notice should be given at once to the medical officer of health of the occurrence of a case of infectious disease.

Bingham, Rural (*Notts*).—Mr. T. Poyntz Wright reports for this sanitary district in 1880 a birth-rate of 30·54 per 1000 of the population, and a death-rate of 19·91. The water-supply of the district is not entirely satisfactory; the geological character of the locality being such as to render the water so hard and so loaded with mineral matter as to make it unfit for domestic consumption. Mr. Wright refers to several instances in which this difficulty has been successfully overcome by providing soft-water cisterns for houses. Alluding to the occurrence of typhoid fever in the district, Mr. Wright observes that in nearly every instance the disease has been produced by water which has become contaminated. The infant mortality of the district is in excess of what it should be, and Mr. Wright has some interesting remarks upon the relations of this mortality to the impoverished condition of the labouring classes during periods of agricultural depression, to bad and insufficient clothing and feeding of the children, and to general maternal neglect.

Stretford, Urban (*Lancashire*).—Mr. G. W. Pettinger reports for this district in 1880 a birth-rate of 27·25 per 1000 of the population (20,000), and a death-rate of 16·95. The prevalence of diarrhœa in August and September appears to have been the most noticeable fact of the health history of the year, and led to much limewashing and disinfection of privies. Mr. Pettinger thinks that "great heat and improper feeding, with a large number of delicate and atrophied children, are the chief causes of so great a mortality in that season of the year." The sanitary condition of the district is said to be much improved, and it would appear that old privies are being converted into new ones on better principles.

Greenock.—Dr. Wallace reports for the five weeks ending April 2nd a total mortality in that town at an annual rate of 18·4 per 1000 of the population. The most noticeable features in the disease history of the period were the diminution of cases of measles and the continuance of typhus. The cases of typhus embraced eleven distinct households, and had, in the majority of instances, a connexion with one another, or with cases formerly reported on.

Weston-super-Mare, Urban (*Somersetshire*).—Mr. C. Vernon Hitchins gives a very favourable report of this district for the past quarter. The total mortality was at the low annual rate of 12·7 per 1000 of the population, and no death was registered from any zymotic disease.

Huddersfield, Urban.—Dr. Cameron reports for this borough during the five weeks ending April 2nd, births equal to a yearly rate of 32·09 per 1000 inhabitants, and deaths equal to a yearly rate of 20·68. The sickness reported to the sanitary authority under the local Act in force in the borough is generally stated to have been "fever," and to have chiefly consisted of cases of scarlatina of a mild type. No return is given of cases treated in the sanitary hospital.

THE METROPOLITAN ASYLUMS BOARD AND THE LOCAL GOVERNMENT BOARD.

At a recent meeting of the Metropolitan Asylums Board the following resolution was adopted:—"That, in consideration of the alarming and continued increase of the epidemic of small-pox in the metropolis, and having regard to the recent decision of the House of Lords (in the case of 'Hill *v.* the Metropolitan Asylums Board'), a decision which has completely fettered the action of the managers, the Local Government Board be urged that immediate legislation is necessary, and that a Bill should at once be introduced into Parliament to define, and, if necessary, to enlarge, the powers of the Metropolitan Asylums Board and the several local authorities, to enable them to deal with epidemic disease in a successful and satisfactory manner, without molestation, and to discharge the duties which the Act of 1867 imposed upon them." That the Asylums Board should find itself compelled to take this course sufficiently indicates the anomalous nature of its relations with the Central Board. Hitherto it has been obviously a case of the blind leading the blind, and now it appears that the led are called upon to advise the leaders as to their leading. But it is not the law as to the metropolis which alone requires reconsideration as to the matters to which the resolution refers, but the general Public Health Law on the subject. The local authorities in the provinces are scarcely less subject to discomforts in respect to infectious disease hospital accommodation than the local authorities in the metropolis, and from similar defects in the Public Health Law. Until these discomforts and disabilities are swept away it is idle to expect that these special hospitals will be promoted to the extent that is desired in the interests of the kingdom.

Our readers will probably remember that the Lower Thames Joint Sewerage Board disputed an account of Dr. Collum, of Kingston, which amounted to £31 10*s.*, fees charged for services to the Board, and offered him £5 5*s.* in discharge of the claim. Dr. Collum refused to accept this, and proceeded against the Board in the County Court for the sum originally charged. The case was recently heard before the Judge of the Court, Vernon Lushington, Esq., Q.C. It appeared that meanwhile the joint Board had paid into the Court £15 15*s.* in satisfaction of the claim. The learned Judge, however, granted the original amount claimed by Dr. Collum, and commented somewhat strongly on the pettiness of the action taken by the joint Board.

Mr. Dodson, asked in the House of Commons by Mr. Hopwood, in reference to some proceedings of Dr. Stevens respecting the vaccination of infants in workhouses, had no hesitation in throwing over, after a fashion, his medical superintendent of vaccination arrangements, the circular of his own department respecting the importance of these workhouse vaccinations, and the law as it had been acted upon by his predecessors. Persons might have thought the question of vaccination a sufficiently difficult one in public administration at the present time, without its difficulties being augmented by the Minister who is responsible for the administration!

A curious case is reported from the Croydon Police Court. A woman was brought before the magistrate, charged with having absconded from the workhouse infirmary, Duppas-hill. She had been engaged in attending as a nurse upon cases of small-pox up to the day but one before, when she had first been sent into the general wards of the infirmary, and afterwards exposed among many persons in the police-station. The magistrate held that the exposure had been monstrous, directed the nurse to leave the Court, and the witnesses against her, and ordered inquiry to be made into the matter, but cautiously delegated the inquiry to other persons.

Mr. Wynter Blyth's number of his "Sanitary Chronicles for the Parish of St. Marylebone," containing his report for the quarter ending March 31st, commences with the peculiarity of limiting the account of the meteorology of the quarter to the month of March only. He introduces, moreover, certain "epidemic forecasts" relating to small-pox, for which he asks the same kindly consideration as has been given to weather forecasts. He discusses, also, "oleomargarine or butterine," and gives some directions (with illustrations) to enable the ordinary observer to ascertain whether he is dealing with butterine or butter.

Barking is considering the propriety of forming itself into a Local Board, but not before it is time, according to the statement of a speaker at the public meeting called to consider the question, and who said that there was no responsible authority in the town to look after the interests of the ratepayers, and to carry out the improvements which from time to time were necessary to prevent houses from being "tucked up" in back gardens without regard to decency and order, and from being infamously constructed, and without proper sanitary arrangements.

A curious vaccination scare was created in the neighbourhood of Dudley a few days ago, where a rumour was spread that the children in the Board Schools were going to be vaccinated by "three American black doctors." The mothers took the alarm and flocked to the schools armed with various ready missiles, and in a few instances windows were broken before the excited women could be convinced that they had been made the victims of a hoax.

Dr. Orme Dudfield's report on the health of Kensington for the four weeks ending April 23rd has interesting details of the occurrences of small-pox and other matters in the parish during the period, as well as of further proceedings relating to small-pox accommodation, which appear to have been substantially adopted by the Metropolitan Asylums Board; also a brief statement of the result of the late deputation from the metropolitan vestries and other bodies on the compulsory notification of infectious diseases &c. to the President of the Local Government Board.

The Thames River Bill (No. 2), brought into the House of Commons by Mr. Chamberlain and Mr. Ashby, although chiefly devoted to the abolition of compulsory pilotage and the free navigation of the river above Gravesend, and the better regulation of the traffic thereon (particularly with regard to the use of steam launches in the upper reaches), contains also provisions for successive owners and occupiers to be affected by notice as to flow of sewage, and for power to inspect lands &c. in relation to sewage &c.

A woman was committed for trial by the sitting magistrate at Hammersmith a few days ago for having given a false address on registering the birth of a child, the object being to conceal it from the vaccination officer. The death of the child, when the real place of residence was registered, led to the discovery of the fraud.

The relieving officer of Islington has proceeded in the Queen's Bench Division of the High Court of Justice against one of the district medical officers for libel in certain somewhat free comments which the medical officer had expressed upon his conduct in the pursuit of his duties. Judgment was given for the defendant, with costs.

Attempts on the part of the sanitary authorities of Fulham, Kensington, and Woolwich, to provide temporary hospital accommodation for cases of small-pox, have each been met with great local public opposition; and in the case of Fulham, the opposition has been carried into the courts of law.

The City of London has determined to use its port hospital ship *Rhin*, at Gravesend, for the isolation of convalescent cases of small-pox from the City, but it is not explained how exigencies on board ships entering the Thames during this use of the hospital ship are to be met.

Glasgow has received the contagion of small-pox from a body of emigrants who had passed by way of Leith through Edinburgh. Both cities are much perturbed by the untoward event.

Three members of the Aberdeen School Board were unable to attend a recent meeting from sickness caused by the so-called milk epidemic in the city.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality continues satisfactorily low. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5330 births and 2944 deaths were registered last week. The births exceeded by 144, while the deaths were so many as 313 below, the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had steadily declined in the four preceding weeks from 22·9 to 20·1, was equal to 20·2 last week. The lowest rates in the twenty towns last week were 14·5 in Plymouth, 15·6 in Bristol, 15·8 in Brighton, and 16·9 in Norwich. The rates in the other towns ranged upwards to 22·8 in Manchester, 23·7 in Newcastle-upon-Tyne, 24·0 in Oldham, and 26·5 in Wolverhampton. During the first six weeks of the current quarter the death-rate in the twenty towns averaged 21·5 per 1000, against 24·0, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 374 and 410 in the two previous weeks, were 396 last week; these included 114 from measles, 74 from whooping-cough, 70 from small-pox, 55 from scarlet fever, 32 from diarrhœa, 27 from fever (principally enteric), and 24 from diphtheria. The annual death-rate from these principal zymotic diseases averaged

2·7 per 1000 in the twenty towns, and ranged from 0·0 both in Brighton and Plymouth, to 3·2 in Sheffield, 3·4 in London, and 3·5 in Oldham. Measles showed the largest proportional fatality in Bristol and Sheffield, and scarlet fever in Salford. The highest death-rates from "fever" were recorded in Liverpool and Oldham. The 24 deaths referred to diphtheria in the twenty towns included 16 in London and 4 in Portsmouth. Small-pox caused 77 more deaths in London and its outer ring of suburban districts, and 1 in Liverpool, whereas no fatal case of this disease was recorded in any of the eighteen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 942 and 1093 at the end of the two preceding weeks, further rose last week to 1225 on Saturday last, of whom 131 were convalescents temporarily accommodated in tents at Darenth. The new cases admitted to these hospitals further rose to 379 last week, from 178 and 363 in the two previous weeks. The Highgate Small-pox Hospital contained 86 patients on Saturday last, and 23 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had steadily declined from 395 to 297 in the four preceding weeks, further fell to 254 last week, and were 38 below the corrected average number in the corresponding week of the last ten years; they included 146 from bronchitis and 87 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 3·5 per 1000 in London last week; while the rate from the same diseases was equal to 5·7 in Liverpool.

The causes of 51, or 1·7 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·1 per cent. in London, whereas it averaged 2·3 in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth, Plymouth, Nottingham, Salford, Sunderland, or Newcastle-upon-Tyne; while the proportions of such deaths were largest in Sheffield and Wolverhampton.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half persons, the annual death-rate last week was equal to 20·6 per 1000, against 21·2 and 21·4 in the two preceding weeks; this rate exceeded the average rate prevailing in the twenty English towns by but 0·4. The rates in the eight Scotch towns ranged from 13·3 and 16·6 in Greenock and Dundee, to 22·2 and 31·8 in Glasgow and Paisley. It is noted that the rate in Paisley is probably over-stated by an under-estimate of its present population. The deaths referred to the principal zymotic diseases in the eight towns, which had been 64 in each of the two preceding weeks, rose to 82 last week; they included 24 from whooping-cough, 20 from diarrhœa, 12 from "fever," 12 from scarlet fever, 7 from diphtheria, 7 from measles, and not 1 from small-pox. The annual death-rate from these zymotic diseases averaged 3·2 per 1000 in the eight towns, and exceeded the average rate from the same diseases in the twenty English towns by 0·5. This zymotic rate in the eight Scotch towns ranged from 0·0 and 1·5 in Perth and Aberdeen, to 3·8 and 5·2 in Edinburgh and Leith. The 24 fatal cases of whooping-cough showed an increase of 13 upon the number returned in the previous week; 13 occurred in Glasgow, 4 in Edinburgh, and 3 in Leith. The 20 deaths referred to diarrhœa showed a further increase upon recent weekly numbers, and were proportionally more numerous than those attributed to the same cause in the English towns. The 12 deaths from "fever" (including typhus, enteric, and simple continued) corresponded with the number in the previous week, and included 6 in Glasgow and 2 in Edinburgh; the annual death-rate from this cause was equal to 0·48 per 1000, and was nearly three times the average rate from fever in the twenty English towns. The 12 fatal cases of scarlet fever showed a further increase upon the numbers in recent weeks; no less than 8 were returned in Edinburgh and 4 in Glasgow. All the 7 deaths from measles were returned in Glasgow; and the 7 deaths from diphtheria included 4 in Glasgow, 2 in Edinburgh, and 1 in Paisley. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 116 and 140 in the two preceding weeks, declined to 111 last week, and were equal to an annual rate of 4·4 per 1000, while the rate from the same diseases in London did not exceed 3·4.

HEALTH OF DUBLIN.

The rate of mortality in Dublin showed an increase again last week. The annual death-rate in the city, which had been equal to 32·6, 30·7, and 27·5 per 1000 in the three preceding weeks, rose again to 29·9 last week. During the first six weeks of the current quarter the death-rate in the city averaged 30·1 per 1000, against 21·6 in London and 21·1 in Edinburgh. The 191 deaths in Dublin last week showed an increase of 15 upon the number in the previous week, and included 14, or rather more than 7 per cent., which were referred to the principal zymotic diseases, against 19 and 8 in the two previous weeks. These 14 deaths from zymotic diseases included 8 from fever (typhus, enteric, or simple), 3 from whooping-cough, one each from scarlet fever, diphtheria, and diarrhœa, and not one either from small-pox or measles. The annual death-rate from these zymotic diseases was equal to 2·2 per 1000, while the rate from the same causes was 3·4 in London and 3·8 in Edinburgh. The deaths referred to fever in Dublin, which had been 14 and 3 in the two preceding weeks, rose again to 8 last week, and were equal to an annual rate more than six times as high as the average rate from the same cause in the twenty large English towns. The 3 deaths from whooping-cough showed an increase upon recent weekly numbers; while the fatal cases of the other principal zymotic diseases were again satisfactorily few. The deaths both of infants and of elderly persons showed a further decline from the numbers returned in recent weeks; the increase of mortality in the city, therefore, must have occurred among children and adults aged between one and sixty years.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE PLAGUE.

The latest news received from Turkey in Asia as to plague appears to show that the disease has not extended beyond the area of the somewhat circumscribed district in which it first appeared, and that within this area it has ceased to prevail everywhere, except in the sacred city of Nedjef. The accounts of the progress of the disease to the present are still so incomplete that a connected history cannot well be written, but it would seem that at no time since the reappearance of the disease in this region in 1867 has the malady shown itself in a graver form. The destructive character of the scourge is stated to have been very great in the different villages and among the several nomadic tribes which have been affected by it. Nedjef particularly seems to have suffered much. This important place, although it has more than once been infected by plague in the outbreaks within the period 1872–1877, yet on each of the several times the disease appeared within its walls had but a small number of cases among its population, and but few lives were lost. But on the present occasion the loss of life appears to have been very great, and the infection is reported to be still continuing its ravages without any diminution of its virulence. As one of the two most important burial-places and centres of pilgrimage of the Shiite Mahommedans from Persia (the neighbouring city of Kerbela being the other city here referred to), the occurrence of serious plague in Nedjef is looked upon with the greatest uneasiness by the Ottoman sanitary authorities. To Nedjef and Kerbela are carried annually thousands of bodies from Persia in all stages of decomposition for burial in the sacred soil beneath and under the shelter of the two cities, and the old notion of the connexion of plague with a soil too much encumbered with the dead has again been broached with reference to the prevalences of the disease in this part of Mesopotamia—a notion which simply shows how carelessly the history of the recent prevalences of plague in Mesopotamia has been read by the responsible sanitary authorities. The infected localities have been surrounded by double and even triple sanitary cordons of troops, and the Ottoman sanitary authorities, aided by the nomadic Arab tribes, believe they have succeeded in shutting off the localities from the outer world. But in all the accounts which are given of these measures of quarantine, of which system the cordons form a part, not a word is said of any attempt to deal fundamentally with those local conditions of the marsh villages on the Euphrates, which Surgeon-Major Colvill and others showed were so closely connected with the appearance and development of plague. It does not seem even to be understood that the successive reappearances of plague in this part of Mesopotamia make this persistent recurrence to arbitrary measures of quarantine a wholly farcical proceeding, as unjustifiable as unreasoning—measures which even the persons instituting or claiming them recognise as not to be trusted in the least degree. Notwithstanding the extraordinary stringency of the quarantine measures said to be put in force by the Ottoman Government against the plague-infected districts in Mesopotamia, we cannot learn that a single quarantine power on the Mediterranean or Black Sea littoral has modified its own quarantine restrictions, but continues them as if the Ottoman restrictions did not exist.

FILTERING CAPACITY OF SOILS.

A supplement to No. 13 of the National Board of Health Bulletin, U.S., contains the first part of a report on a series of elaborate researches on the filtering capacity of soils, by Mr. Raphael Pumpelly, of great interest. This preliminary report is confined to the soils and some other substances, as filters, in eliminating living low vegetable organisms from air and fluids, but in this direction a beginning only is professed to have been made. Careful descriptions are given of the methods of research pursued, and already important indications of the value of the results to be obtained in determining the relation of soils to health are given. For example, in a section on filtering bacteria and their germs from liquids we have the following observations and conclusions: "From these results it appears very clearly that sand interposes absolutely no barrier between wells and the bacterial infection from cesspools, cemeteries, &c., lying, even at great distances, in the lower wet stratum of sand. And it appears probable that a dry gravel or possibly a dry very coarse sand interposes no barrier to the free entrance into houses built upon them of these organisms, which swarm in the ground-air around leaky cesspools, leaky drains, &c., or in the filthy made ground of cities;" and, further, it is concluded from the experiments, "That a house may be built on a thoroughly dry body of sand or gravel, and its cellar may be far above the level of the ground water at all times, and it may yet be in danger of having the air of its rooms contaminated by the germs from leaking cesspools and vaults; for if the drift of the leaking be towards the cellar, very wet seasons may extend the polluted moisture to the cellar walls, whence, after evaporation, the germs will pass into the atmospheric circulation of the house." The bulk of the report is chiefly occupied with the detailed results of air and liquid filtrations under different circumstances.

The Sanitary Assurance Association have published in a separate form the lecture recently delivered at the London Institution by Professor F. de Chaumont, F.R.S.; also the short addresses delivered after the conclusion of the lecture by Mr. Erichsen, F.R.S., President of the College of Surgeons, Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S., and Mr. R. Brudenell Carter, F.R.C.S.

Russian journals state that a notice has been affixed in the Students' Hall in the University, inviting volunteers from medical students in their fifth year of study to proceed to the district of Ovroutch, province of Volbynia, to give assistance in dealing with a serious epidemic of smallpox prevailing there.

THE SERVICES.

THE VICTORIA CROSS.

Amongst the recipients of this much-coveted reward is Provisional Lance-Corporal Joseph John Farmer, of the Army Hospital Corps, "for conspicuous bravery during the engagement with the Boers at the Majuba Mountain, on the 27th February, 1881, when he showed a spirit of self-abnegation and an example of cool courage which cannot be too highly commended. While the Boers closed with the British troops near the wells, Corporal Farmer held a white flag over the wounded, and when the arm holding the flag was shot through, he called out that he had 'another.' He then raised the flag with the other arm, and continued to do so until that also was pierced with a bullet."

WAR OFFICE.—The Secretary of State for War has appointed William Walter Weld, Esq., Surgeon-Major, to be Visiting Surgeon at Colchester, under the Contagious Diseases Acts, 1866 to 1869, vice E. Waylen, Esq., deceased, from May 10th inclusively; and James Bell Jardine, Esq., M.D. Edin., L R.C.S. Eng., to be Visiting Surgeon at Chatham, under the Contagious Diseases Acts, 1866 to 1869, vice W. W. Weld, Esq., appointed Visiting Surgeon at Colchester, from May 10th inclusively.

ARMY MEDICAL DEPARTMENT. — Brigade - Surgeon Wallace Haward has been granted retired pay, with the honorary rank of Deputy Surgeon-General; dated April 25th, 1881. Surgeon-Major John Harrison Robotham to be Brigade-Surgeon, vice E. L. Hiffernan, deceased; dated April 25th, 1881. Surgeon-Major Frederick Robert Wilson, M.B., has been granted retired pay, with the honorary rank of Brigade-Surgeon; dated April 17th, 1881. Surgeon-Major Henry Lamb is granted retired pay, with the honorary rank of Brigade-Surgeon; dated May 18th, 1881. Surgeon-Major Edward Nicholson has retired on temporary half-pay. Dated May 8th, 1881. Surgeon John Joseph Crean to be Surgeon-Major; dated May 1st, 1881.

MILITIA MEDICAL DEPARTMENT. — Surgeon Rowland Hill Coombs, Bedford Militia, to be Surgeon-Major.

ADMIRALTY. — The following appointments have been made: Staff-Surgeon Robert J. McMorris, to the *Malabar*, vice MacClinton; Staff-Surgeon John Buckley, to the *Téméraire*, vice Fennell; Staff-Surgeon John Mockridge, to the *Warrior*, vice Buckley; and George W. F. Armstrong, M.D., to the *Ruby*, vice Brunt.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

ON Tuesday afternoon a deputation from this Association had an interview with Mr. Dodson and Mr. Hibbert, at the office of the Local Government Board, for the purpose of urging the desirableness of making the superannuation of Poor-law medical officers compulsory, instead of permissive. The deputation was introduced by Sir Trevor Lawrence, M.P., president of the Association, and included Mr. Thorold Rogers, M.P.; Dr. Lyons, M.P.; Sir W. Palliser, M.P.; Dr. Rogers, chairman of the Council; Mr. Wickham Barnes, hon. secretary; Dr. Norman Kerr; Dr. Burchell; Dr. Elliott Porter, Lindfield, East Sussex; Mr. D. B. Balding, Royston; Dr. Whitwell, Shrewsbury; Dr. Fegan, Woolwich; E. Marshall, Esq., Mitcham; T. Walford, Esq., Reading; O. Lousley, Esq.; Dr. Walter Smith, London; — Bland, Esq., Isle of Sheppey; — Pardoe, Esq., London; Dr. Bain, London; Dr. Young, Aldershot; E. Child, Esq., New Malden; Dr. Smythe, London, &c. Sir T. Lawrence, in opening the subject, remarked that at present the Local Government Board could only recommend that a superannuation should be granted, and said the treatment of medical men after long public service should be such as would tempt men of high qualifications to become poor-law officers.—Dr. Rogers referred to a return showing that of 122 suitable applications to boards of guardians for superannuation fifty were refused, and mentioned instances of refusal after from forty to fifty years' service. He maintained that superannuation should in all fitting cases be compulsory, and that in the event of public opinion proving to be not sufficiently advanced for that the Local Government Board should, after due inquiry, have power to order superannuation.—Mr. Wickham Barnes, after thanking Mr. Dodson on behalf of the Poor-law Medical Officers' Association, and Poor-law Medical officers generally, for granting them this interview, stated that there were one or two points he wished to touch upon—namely, in reference to the returns asked for by Professor Thorold Rogers relating to the applicants for superannuation. Mr. Barnes stated that this return, however valuable, did not give any idea of the demand for superannuation, because before superannuation could be asked for the Poor-law medical officer must resign, which in the great majority of cases he was afraid to do. Referring to the promise of Mr. Sclater-Booth that any deserving case of long continuous service should receive his special attention towards urging on the claim for liberal superannuation, Mr. Barnes mentioned that the cases of Mr. Terry and Dr. Downes (both of whom had served forty years in their respective unions) were brought under the notice of the central authority, and though in one case a

Government inspector was sent down to press upon the guardians the necessity of superannuation, yet no good result followed. Mr. Sclater-Booth laid great stress upon continuous service, but Mr. Barnes thought it often acted prejudicially to the medical officer, who frequently outlived his friends at the Board, the new members having no sympathy with him. Referring to the argument that the Poor-law medical officer did not give his whole time to the service, Mr. Barnes stated that practically he did so, as he never could be absent from his post day or night without leaving a deputy in charge. —Mr. Hibbert asked what the deputation proposed to have done in cases where the service was not continuous in one district.—Dr. Rogers said that in his opinion each district should contribute.—Mr. Dodson, replying, said there were many difficulties connected with superannuation. One was that just referred to by Mr. Hibbert—namely, that in many cases the entire service was not continuous in one union. Another was that where officers did not devote their whole time to the work, it would not be easy to measure or apportion superannuation, and another that Poor-law authorities were the only local authorities that had the power of granting any superannuations. As regarded the suggestion that the Board should have power to arbitrate in the matter, he thought that a centralising measure of that kind would be viewed with considerable jealousy by local authorities. He wished to know whether it was proposed that the power of the Board should apply to existing medical officers, or only to such as might hereafter be appointed.—Dr. Rogers and Sir Trevor Lawrence expressed a desire that the power should be retrospective as well as prospective.—Mr. Dodson added that that would of course alter the conditions of service. The right hon. gentleman proceeded to say that he admitted that there was strength in the arguments which had been advanced, and promised that the matter should be carefully considered by the Board.—Mr. Thorold Rogers, M.P., afterwards pointed out that the guardians who paid medical officers the least were generally those who were most persistent in refusing superannuations.—The interview then terminated.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following is the proposed scheme of education and examination as prepared by the Education Committee and as amended by the Council of the College in committee. It has been adopted by the Council, but has been sent back to the committee for the filling up of certain details, and will then come before the Council previous to its final adoption: Each student shall be required to pass a Preliminary Examination and four Professional Examinations. The Preliminary Examination will include the English language (including grammar and composition), arithmetic (including vulgar and decimal fractions), algebra (including simple equations), geometry (first two books of Euclid), Latin, while the alternative subjects are Greek, French, and German. The First Professional Examination will include physics, the elements of chemistry, botany (descriptive and physiological), anatomy (human osteology), and practical pharmacy. Before admission to the Second Professional Examination candidates must produce evidence of having passed the First Professional Examination, and shall be examined in anatomy, bones, joints, muscles, and topographical anatomy of the viscera of the chest, abdomen and pelvis, histology, and the physiology of the circulatory, respiratory, and digestive systems; surgery —the signs, terminations, and treatment of inflammation, wounds, hæmorrhage, burns and scalds, ulcers, bandaging, chemistry, and materia medica. Before admisssion to the Third Professional Examination candidates must produce evidence of having passed the Second Examination, and will be examined in anatomy, physiology, and surgery. In like manner before being admitted to the Fourth or Final Professional Examination the candidate must prove that he has passed the Third Professional Examination, and shall then be examined in surgery—clinical surgery (including ophthalmic surgery, operative surgery, with surgical anatomy), medicine, midwifery and diseases of women, and medical jurisprudence. The examination in physics may be passed either at the Preliminary or the First Professional Examination, and the anatomical examinations of the second and subsequent years shall include dissection by the candidate of the parts indicated for his examination and demonstration by him of dissected parts.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Monday, the Marquis of Huntly, in reply to a question by Lord Stanley of Alderley as to whether the Government would prohibit the importation of American hams and oleomargarine, said it was very doubtful if the Government had the power of prohibiting the articles named, but the matter had received careful attention.

Metropolitan Food Supply.

In the House of Commons on Friday, May 13th, Mr. Warton called attention to the injurious effect of the London market system in raising the price of food to the consumer, and showed that owing to combinations amongst salesmen and wholesale dealers the producer was often mulcted of his fair profit. The hon. member referred in particular to the unsatisfactory and wasteful arrangements for the sale and distribution of fish at Billingsgate. He had a motion on the subject, put down in the form of an amendment to Supply, but was unable to bring it forward, and at the close of the hon. member's speech the subject dropped. A Government resolution, authorising licences for supplying refreshments on Pullman railway cars, was agreed to.

Limerick Lunatic Asylum.

On Monday, in reply to Mr. O'Shaughnessy, Mr. Forster stated that two insane soldiers were sent from Limerick district prison to the county asylum, where they now remained. Only one was sent from Netley, and he was a native of the county. It would be difficult always to send military lunatics to the asylums to which they were naturally chargeable, but in individual cases the matter might be arranged by the Inspector of Asylums, as was done in this case.

The Basuto Wounded.

Mr. Grant-Duff stated to Mr. Summers that the Government knew nothing of the refusal by the Cape authorities to allow a French missionary to pass through the lines of the colonial forces with medicines and ambulance materials for the use of the Basuto wounded; but there was some correspondence some time ago with the French Missionary secretary, which would be found in the South African papers.

Volunteer Surgeons.

Mr. Donaldson-Hudson asked the Secretary of State for War whether Her Majesty's Government will accord to Volunteer battalion surgeons, after twelve years' service, the rank and title of surgeon-major, as in the case of Militia battalion surgeons; and whether they will give to them, under the Memorandum showing the principal changes in army organisation, &c., intended to take effect from 1st July, 1881, the same privileges upon retirement, after fifteen years' service, as to other officers of the Auxiliary Forces. Mr. Childers said Volunteer surgeons would be put on the same footing as Militia surgeons—viz., after twenty years' service they would receive a step of promotion, or in case of retirement after that period a step of honorary rank, and they would also be entitled to retain their rank on retirement.

The Alkali Bill.

Mr. Dodson, in answer to Mr. Warton, said complaints were made before the Royal Commissioners of the noxious gases emanating from cement works, but no sanitary authorities had made any representation to the Government on the subject.

The Vaccination Act.

On Tuesday, Mr. P. A. Taylor asked the Secretary of State for the Home Department whether it was the fact that the Warrington magistrates recently fined six persons £1 16*s.* 6*d.* each (including costs) under section 29 of the Vaccination Act, which section applies only to children under twelve months old, whereas the children in question were from three to six years old; whether this was not illegal; and whether he would direct that the fines be remitted.—Sir W. Harcourt replied that he only received the facts of this case this morning. It appeared that the conviction did take place under the 29th section of the Vaccination Act, and such a conviction, as suggested in the question, would be irregular and improper. The proceedings should have been under the 31st section. He would inquire into the matter and see what was to be done.

The Contagious Diseases Acts.

MR. Hopwood gave notice that on Friday he will ask the Secretary of State for the Home Department, whether it is the fact that one or more surgeons employed in the compulsory examination of prostitutes under the Contagious Diseases Acts have been made justices of the peace, in order that they may carry out the Acts in a twofold capacity, administering and executing the law; whether he will state by what Minister such gentlemen were recommended to Her Majesty for appointment; whether he approves of such a confusion of duties; and whether the individuals in question should not be called upon to make their choice once for all to act either as magistrates or as surgeons.

The Case of Captain Chatterton.

On Thursday, Mr. Grantham asked the Secretary of State for India, as he has now received the promised reports from India on the case of Captain Chatterton, if he can tell the House whether by the report of the Medical Board, dated Sept 5th, 1868, signed by Surgeon-Major Peskett, Surgeons Lowdell and Condon, and Assistant-Surgeon Walsh, at Myne Tal, Captain Chatterton was not recommended to take twelve months leave of absence, for the purpose of returning to England to undergo an operation—viz., the division of the left tendo Achillis, on the ground that it was not safe to perform the operation in India; whether Surgeon-Major Powell, acting as garrison surgeon in Fort William, Calcutta, did not afterwards in April, 1869, confirm the above recommendation on the same ground; and whether the only report on which the despatch of June 5th, 1869, ordering the compulsory retirement of Captain Chatterton, was founded, and which practically alleged that he was shamming, was not that made in November or December, 1868, by Assistant-Surgeon Macdermott, who was shortly afterwards removed from the medical charge of that and other cases previously under his care; and how it was that Captain Chatterton was dismissed the army in 1869, on the report of an assistant-surgeon, when Captain Chatterton was acting on the reports of very eminent surgeons, made both before and after the report of the assistant-surgeon.—The Marquis of Hartington said it was true that the Medical Board recommended that Captain Chatterton should be sent to England to undergo an operation. It was afterwards found there was no occasion to send him home, as the operation was a very simple one and could be performed in India. The decision was overruled by a higher authority. The action taken with respect to Captain Chatterton was not only founded upon the report of Assistant-Surgeon Macdermott, but on the report of the Court of Inquiry. This Court took the evidence of several military officers of experience, and the report was considered by the Commander-in-chief in India, and on the report and after communication with the Field-Marshal Commanding-in-Chief, the Secretary of State placed Captain Chatterton on half-pay. He had not been dismissed; but out of fifteen years and a half, he had been six and a half on medical leave, and claimed another year. On these grounds the Government were entitled to place him on half-pay.

Animal Vaccine.

Dr. Cameron asked the President of the Local Government Board what has been done since Dr. Cory's appointment to provide for the public supply of vaccine lymph direct from the calf; whether the Vaccination Department has been, or will be, instructed to issue lymph free for purposes of revaccination to all medical men who may ask for it; and what steps have been taken to supply adequate hospital accommodation for small-pox cases, and so put an end to the public danger which arises from the treatment of so many cases of that disease in their own homes, and the consequent maintenance of so many separate foci of disease.—Mr. Dodson said great and unexpected difficulty had been found in obtaining the necessary premises for the new vaccine establishment, but premises had now been secured and the necessary alterations were being made without delay. Preliminary arrangements had been made, under which, as soon as the buildings were ready, a succession of calves would be provided. He feared it was not practicable for the department to undertake to supply lymph for revaccination to any medical man who might apply. Accommodation had been provided for a considerable number of convalescent patients on the property of the Metropolitan Asylums managers at Darenth, and owing to the unremitting and praiseworthy efforts of the managers 251 convalescent patients had been removed there in one week. Negotiations were going on with a view of obtaining additional accommodation, but the matter was one of great difficulty owing to the proceedings taken in some cases, and threatened in others, of closing existing hospitals or preventing them being opened.—Mr. Sclater-Booth asked whether the Government did not intend to propose legislation with a view to give the Asylums Board the power which they ought to have in order to carry out the objects of the Act of 1876?—Mr. Dodson said he would be glad to confer with any one who would advise him as to what were the requisite powers.—Dr. Cameron gave notice that he should take the first opportunity of drawing the attention of the House to the subject.

THE FARR TESTIMONIAL FUND.

A MEETING of the Executive Committee, charged with the promotion of the testimonial to Dr. William Farr, C.B., M.D., F.R.S., was held at Somerset House on Thursday afternoon last. It was announced that the net proceeds of the subscription amounted to £940. It was decided that this sum should be at once invested, and that every effort should be made to obtain the remaining £60 required to raise the Testimonial Fund to £1000, which it is proposed, at the request of Dr. Farr, to invest in the names of trustees for the benefit of his family. Any contributions towards meeting this deficiency will be thankfully acknowledged by the Honorary Secretary, Mr. Noel A. Humphreys, General Registrar Office, Somerset House.

DR. KIDD ON THE CASE OF THE EARL OF BEACONSFIELD.

To the Editor of THE LANCET.

SIR,—A few weeks' absence from England prevented my replying to the remarks in THE LANCET of April 16th.

The following information as to the case of the late Lord Beaconsfield may interest your readers. For some months before I had the honour of originally attending Lord Beaconsfield he had been attended by Sir William Jenner, but in vain, as his treatment failed to relieve. Sir William Gull also was called in, but his treatment again failed to relieve the patient. By the vigorous application of "one set of convictions" I was enabled to afford prompt and perfect relief for three years and a half.

Self-respect and regard for the honour of the medical profession prevented my noticing Sir William Gull's letter to the *Standard*, but I desire now in the proper place to protest against his accusation. I never advised "compromise;" my worst enemy never accused me of it. The aim and object of my little volume, "The Laws of Therapeutics," is to destroy compromise, to protest against eclecticism and schism, to bring the "catholic spirit" into medicine, gathering "all knowledge" to the aid of suffering humanity, and thus to help the introduction of scientific precision into therapeutics. I remain, yours faithfully,

May 17th, 1881. J. KIDD, M.D.

P.S.—A week before THE LANCET drew my attention to the fact that my name still appeared in "The British Homœopathic Directory" and "The Homœopathic Medical Directory" for 1881, and on the list of the Medical Council of the Homœopathic Hospital, I wrote requesting that it might be withdrawn from all.

MEDICAL VOLUNTEERS.—The committee of the National Rifle Association have acceded to the request of the United Hospitals' Rifle Association, that their challenge cup should be shot for at Wimbledon, and have named July 18th for the competition. This cup is of the value of fifty guineas, and is offered for annual competition by members of the metropolitan hospitals, being efficient volunteers. Any further information will be readily given by the hon. secretary, Mr. G. S. Pollard, Guy's Hospital, S.E.

SKETCHES OF CONTINENTAL HOSPITALS.

(*By our Special Correspondent.*)

BOLOGNA.

The rich city of Bologna, with its magnificent churches and ancient university, is well deserving of a lengthened description. It holds pre-eminence among the medical schools of Italy, not merely on account of its past scientific traditions, but because it boasts at the present day professors of the highest ability, and a clinical hospital which is on a par with the most recent and well-managed institutions of a similar character either in England, France, or Germany.

The old university in the Archiginnasio Antico is memorable as containing the anatomical theatre in which Morgagni and Galvani lectured. It is a room of noble proportions, lined with cedar, and capable of containing 150 people. The rostrum, or pulpit, in which the professor stood, is surmounted by a baldachino, the supports of which are two life-sized anatomical figures, the one showing the muscles and the other the vessels. Around the room are marble busts of the great masters in medicine and anatomy. At one end are ranged Hippocrates, Galen, and Malpighi, while opposite to them are Varolius and Arantius. The busts at one side of the theatre represent Mondinas, Argiolata, and Varignano, while those on the other recall the frames, if not the features, of Fracosatus, Bartolettus, and Taliacotius.

Galvani, who was Professor of Obstetrics in this University, made his celebrated experiments on the frog in this theatre in 1786. Here also lectured Malpighi, Valsalva, and Mariani, of all of whom handsome marble statues have been erected in the adjoining loggia. Near to them, also, is a monument of great curiosity. It is dedicated to Anna Maria Mansolini, a lady who once held the Chair of Anatomy in this University. Adjoining the anatomy theatre, which, by the way, is now no longer used, is the magnificent library in which the great linguist Mezzofanti laboured. The series of rooms in which the books are admirably arranged is upwards of 600 ft. in length, and is rich in the possession of the noblest works of all the languages of the world. The acquisition of forty-two languages and seventy dialects by the marvellous librarian may, thus, in some small degree, be accounted for.

The Archiginnasio Antico is now no longer used as a medical school; that has been removed with the other departments of literature and science to a handsome and extensive new range of buildings. At the present time there are between 400 and 500 medical students, about 250 of whom are following the systematic courses of the university, while the remainder are pursuing their clinical studies at the hospitals. The academical course is much more extended than in the British isles; of the six years required to be spent in the acquisition of professional knowledge three are occupied with systematic lectures in the university, and three in the various hospital cliniques. The latter part of the time is not necessarily spent at Bologna, but may be passed at Florence or Milan, where there are also large clinical hospitals, to which I shall call attention in a future article.

The museums of the university are of great value, and embrace an enormous number of dissections and admirably executed wax preparations. There are separate rooms for: 1. Osteology. 2. The muscular system. 3. The organs of circulation. 4. The nervous system. 5. Embryology. 6. Zoology. In addition, there is a pathological museum containing many valuable specimens of the various branches of external and internal pathology, which is especially rich in illustrations of the deformities produced by rachitis and osteo-malachia. The dissecting-room is small considering the number of students, and is provided with only twelve tables.

The Clinical Hospital of St. Ursula is just outside the walls of Bologna, and close to the Porta St. Vitale. It occupies a large extent of ground and has gardens around it, in which a large quantity of vegetables for the use of the patients is grown. The front of the hospital is plain and unimposing; the wards in that part are low, and such as might be expected in an old convent, but at the back of them a handsome new building was erected in 1870, capable of holding 220 beds, and this part is used for clinical instruction. The new wings are well arranged, and fitted with every convenience: the floors are of stone and kept remarkably clean; the windows in the wards are large, they are placed opposite to each other, and reach up to the ceiling. Over the head of each bed is an electric bell, so that a patient can without difficulty summon one of the nurses; the bedsteads are of iron, and each has a movable wooden footboard. The mattresses are of horsehair, and beneath them is an iron spring netting, so that the beds are thus made very comfortable. The waterclosets are clean and sweet, the seats being of white marble, and the supply of water ample. In each corridor is a bath-room, with a large metal bath. The larger wards have thirty-two beds, the smaller from six to eight. The nursing is done by paid nurses in ordinary dress, there being three to each of the larger wards and one to the smaller. Sisters of Charity are conspicuous by their absence; and, *mirabile dictu*, there are for the spiritual needs of this large hospital only two priests among the list of officers! It is evident that the hand of reform has thus been at work in this once priest-ridden place, which formerly was, next to Rome, the most important city of the Papal States, and which literally swarmed with monks of every order in Christendom. There are special wards for syphilis, with twenty-five beds for men and an equal number for women; the latter patients are kept under lock and key, and are very closely looked after. It is the practice to submit all prostitutes to periodical examination, but in spite of this, syphilitic diseases are of great frequency. The treatment adopted in such cases is much the same as that employed in England: mercury being used in the primary and iodide of potassium in the secondary forms. For leprosy and psoriasis an ointment of chrysophanic acid is in great repute; for eczema, unguentum picis is much in vogue.

There are no special wards for children. Simple fractures are mostly treated by immobilisation with plaster-of-Paris or silicate of potass bandages, and compound fractures by the apparatus of Scultetus with a many-tailed bandage, the limb being kept *in situ* by means of bran pads.

Resections of joints are said to be frequent, but I did not see any at the time of my visit. Lister's treatment is in general use, and I may mention two cases in which its good effects were manifest. One was the case of a man with an extensive lacerated wound of the axilla, in which rapid union by the first intention had taken place, and the other was a man with a crushed foot, for whom a Chopart's amputation had been performed three weeks previously, and in whom the stump was all but healed. In one case of compound fracture of the leg, where three fragments of the tibia had been extracted, the wound had been dressed with lint dipped in a solution of carbolic acid, and in six weeks union was perfect. Stone in the bladder is a common disease; Professor Loreta has had upwards of one hundred operations, and on this subject he has published a valuable memoir. He performs the lateral operation, but with special instruments designed by himself and manufactured by Lollini of Bologna. He uses a beaked knife with a movable back, and a staff which is centrally grooved, the said groove being broad at the handle and narrowing towards the point, so that when the knife is pushed along the staff it cannot slip out of the groove unless withdrawn by the operator; the movable arrangement of the back of the knife also allows the blade to be lateralised in the after part of the operation, so that the prostate is not entirely cut through. The instruments have been very successful in Professor Loreta's hands, and no doubt they will be found serviceable, especially by young or inexperienced operators.

Plenty of material is always on hand for clinical teaching, and large classes attend the visits of the various professors. The operating theatre will accommodate 150 students, and is well arranged and lighted. Around the walls are busts of former surgeons of eminence, as Alti, Venturoli, Rizzoli, Landi, Fabbri, and Magni. The instruments and surgical apparatus are abundant, and of the best quality. The thermo-cautery of Paquelin is a favourite instrument, particularly for malignant tumours of the uterus.

I might say much more in praise of this hospital, but I cannot conclude without calling attention to the excellent post-mortem room and pathological department, which are in a separate building at the back of the grounds, and approached by a long corridor with open windows on either side. In the theatre of this building the practical examination in surgery for the doctorate of the university is carried out, and candidates perform operations on the dead body, not only in the presence of the examiners, but also before the general body of students. In one examination I witnessed the subject was tied up in a chair as though it were a living being, and among other operations resection of a portion of the lower jaw had to be performed. A more practical or searching system of examination is rarely to be met with than that which prevails for the degrees of the University of Bologna.

Obituary.

DR. HUMPHRY SANDWITH, C.B., D.C.L.

DR. HUMPHRY SANDWITH was born at Bridlington in 1822, and died in Paris on the 16th inst. He was the son of a well-known physician in Yorkshire, and in 1849 settled in practice at Constantinople. He was subsequently attached to Mr. Layard's expedition to Nineveh. In 1853 he joined General Beatson's force of Bashi-Bazouks on the Danube as medical officer, and was afterwards appointed chief of the medical staff of the force engaged in the defence of Kars, under Sir Fenwick Williams, an account of which he published under the title of the Siege of Kars. On the termination of the siege, General Mouravieff gave Dr. Sandwith his liberty in acknowledgment of the services he had rendered to the Russian wounded. For these services he was made a Companion of the Bath, and had the honorary degree of D.C.L. conferred on him by the University of Oxford. In 1857 he was appointed Colonial Secretary of Mauritius, but resigned the appointment in 1860. He contested unsuccessfully the Borough of Marylebone as an advanced Liberal in 1868. During the Servian and Russian campaigns he took an active part in organising hospitals and providing for the care of the wounded. He died in Paris after an illness of three weeks.

Medical News,

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — The following gentlemen were admitted Fellows of the College on May 16th :—

Black, James Watt, M.D. Edin., Clarges-street.
Ewart, Joseph, M.D. St. And., Brighton.
Ewart, William, M.B. Camb.,Curzon-street.
Hall, Francis de Havilland, M.D. Lond., Queen Anne-st.
Hicks, J. Wale, M.D. Lond., Sidney College, Cambridge.
Lees, David Bridge, M.D. Camb., Thurloe Houses.
Potter, J. Baptiste, M.D. Edin., George-st., Hanover-sq.
Turner, Francis Charlewood, M.D. Camb., Finsbury-sq.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on Monday last :—

Bassett, W. F. Prichard, M.B. Ed., Bathurst, N. S. Wales.
Burton, William Henry, M.B. Toronto, Tottenham.
Grinling, John Campion, Barton-under-Needwood.
McCormick, Alexander, M.B. Edin., Edinburgh.
Verrey, Louis, M.D. Leipzig, Lausanne, Switzerland.
Wells, Charles M.D. Queen's Univ. Irel., Stowmarket.
Willett, George Gilmore Drake, Bristol.
Woodruff, John Winthrop, Wallington, Surrey.

The following gentlemen were admitted Members of the College on Tuesday last :—

Batson, Robert Sewell, Torrington, Devon.
Branson, G. Attenborough, L.R.C.P. Ed., Ladbroke-grove-rd.
Green, Harry, L.S.A., Cound, Shrewsbury.
Keys, Elias, Plymouth.
Maitland, Alfred Derwent, Hyde Park-square.
Minchinton, Henry James, Brixham, Devon.
Mivart, Fred. St. George, L.R.C.P. Ed., Devonport-street.
Newsholme, H. Wilkinson, Hellifield, near Leeds.
Pritchard, Owen, L.S.A., Anglesea.
Ramsden, Albert, Clapham.
Thane, Philip Thornton, Montague-street.
Thornton, Bertram, Margate.
Willis, Arthur, L.S.A., Soham, near Ely.
Willis, Arthur Keith, St. George's-road, Kilburn.

The following gentlemen were admitted Members on Wednesday last :—

Alexander, Frederick William, Hatton Garden.
Chard, R. A. Selway, Upton Lovell, Wilts.
Coutts, Joseph Alfred, Aldridge-road.
Currie, Oswald James, Blackheath.
Dixon, George Frederick, Market Harborough.
Jones, William Wansbrough, Macclesfield.
Owen, John Morgan, Fishguard, Pembroke.
Rigby, John, L.S.A., Preston.
Rowley, Charles, Barnsley.
Shore, Robert George, Stoke, Staffordshire.
Tripp, C. L. Howard, Tiverton, Devon.
Wood, Louis Edmund, Marlborough, Wilts.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 12th, 13th, and 14th inst. :—

Stephen R. Thompson, Frederick W. C. Jones, Aubrey D. Chapple, Henry G. Read, Francis H. Julyan, Maitland Thompson, and Walter T. Strugnell, St. Bartholomew's Hospital; Alexander G. Andrews, Richard L. Holland, Francis E. Little, Arthur E. Hayward, and Frederick A. N. Bateman, St. George's Hospital; Lionel J. Shepherd, John Llewellyn, Henry R. Kenwood, and Alfred F. Peskett, London Hospital; William A. Aikin, James P. Martin, Alfred Linnell, Herbert R. Mead, William L. W. Marshall, Alfred L. Scott, and Arthur J. Carter, Guy's Hospital; Henry R. Hodges, Alfred G. Webster, George Wale, Sidney Herbert, and Anton H. Syree, King's College; John Scott, Cambridge and St. Bartholomew's Hospital; Frederick W. McDonogh, Herbert W. Hart, Herbert J. Pulling, and George S. Baker, Westminster Hospital; George H. F. Ferguson, Newcastle-on-Tyne and St. Thomas's Hospital; George Herbert, University College; Reginald B. Anderson, Middlesex Hospital.

Of the 144 candidates examined during last week 59 failed to satisfy the Board of Examiners, and were referred for three, and 10 candidates for six, months' further anatomical and physiological study. The Primary Examinations in Anatomy and Physiology for the Membership of the College, which commenced on April 1st, were brought to a close on the 14th inst. The total number of candidates examined was 543, which will be found to be greatly in excess of previous years. The rejections were 164. The First Part of the Professional Examination for the Fellowship commences this day (Friday), for which there are over 100 candidates.

The Library of the College will be closed on Friday and Saturday the 27th and 28th, and also on the following Monday, May 30th, for the Fellowship Examination.

UNIVERSITY OF CAMBRIDGE.—The following gentlemen passed the First Part of the Examination for the degree of M.B. :—

FIRST CLASS.
Fuller, H. R., B.A. Caius.

SECOND CLASS.
Bagshaw, M.A. St. John's.
Birdwood, B.A. St. Peter's.
Browne, P. A., M.A. Trin.
Howe, B.A. Clare.
Marshall, B.A. Clare.
Tooth, M.A. St. John's.
Webber, B.A. Downing.

APOTHECARIES' HALL. —The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on May 12th :—

Greenleaf, Alfred William, Alderney-street, Pimlico.
Kemm, Frederick St. John, London Hospital.

COLLEGE OF PHYSICIANS IN IRELAND. — At examinations held on the 9th inst. and succeeding days, the under-mentioned obtained the licences in Medicine and Midwifery of the College :—

Augustus James Arthur Browne, Louis John Patrick Carroll, Walter John Clarke, Edmond Francis Flynn, James Garland, Edward Gloster, Thomas Higgins, William Wall Jacobs, Patrick Andrew McDermott, Harry Strickland McGill, John Henry Cornelius Maw, George Cathcart Montray, William Joseph O'Keefe, and Thomas Kay Whitehead.

The following Licentiates have been admitted Members :—

Dane, Arthur Henry Cole, Surg. Bombay Army.
Lamb, H. Surg-Maj. A.M.D.
Marques, Lourenzo Pereira.
Nugent, Edward Joseph.
Whitty, Patrick J.

ROYAL COLLEGE OF SURGEONS IN IRELAND. — At the April examinations the following obtained the licence in Surgery :—

Howard W. Acheson, James A. Baird, Charles D. Barrett, John Brady, John G. W. Bullock, Richard Callan, John P. J. Coolican, Patrick J. Dempsey, John B. Dunlop, Frederick D. Elderton, John S. Gelston, Walter Jones, Michael F. Kenna, Thomas W. Lewis, James C. McMullen, John H. O'D. McGuinness, Claude H. McSwiney, Michael C. Maloney, Edmond Murphy, George Nelis, Augustus Nickson, Francis R. O'Brien, Joseph F. O'Carroll, Edward H. O'Doherty, Michael J. O'Doherty, John A. C. Penny, John A. Powell, Robert Power, James Quirke, Thomas O'C. Redmond, Alexander Ross, Ventry A. J. Smith, Jones C. L. Stawell, Robert J. Tate, Macnamara M. Williamson, Augustus Woodroffe.

IT is expected that the Prince and Princess of Wales will be present to open the new Marylebone Infirmary at Notting-hill early next month.

THE subscriptions received at the festival dinner on the 13th inst. in aid of the funds of the Middlesex Hospital, Earl Derby in the chair, amounted to £3000.

DR. J. C. BRUMWELL has been nominated to the Commission of the Peace for Burnley.

THE salary of Dr. Young, medical officer of the Farnham Union, has been increased by £5 annually.

MR. J. S. STEELE, late Medical Officer in the Reigate Union, has received a superannuation allowance of £70 a year.

SOCIETY OF MEDICAL OFFICERS OF HEALTH. —The next meeting has been fixed for Friday, May 20th (this day), at 7.30 P.M., at 1, Adam-street, Adelphi, when B. W. Richardson, M.D., F.R.S., will read a paper entitled "A Study of the Periods of Incubation of the Communicable Diseases."

THE Hospital Saturday collections in aid of the local medical charities were made at Birmingham last week at nearly all the manufactories and other places of business in the town. The total sum as yet received is £2947 13*s.* 9*d.* It may be interesting to know the amounts realised in previous years: 1873 (first year), £4215; 1874, £3850; 1875, £3606; 1876, £3484; 1877, £3069; 1878, £2994; 1879, £3330; 1880, £3666.

MEATH HOSPITAL, DUBLIN.—The following prizes were presented last week to students attending this hospital:—Medical Prizes: Reginald Mosely, first; Donald Grant, second; Macnamara Williams, third. Senior Surgical Prizes: Howard Atkinson, second; Frank J. Newell, third. Junior Surgical Prizes: Timothy Howard, first; James Bolger, second; Percy Newell, third. The gentleman who obtained the First Senior Surgical Prize was unable to be present at the distribution.

A MEETING in aid of the East London Hospital for Children and Dispensary for Women, Shadwell, was held at the Mansion House on Monday, under the presidency of the Lord Mayor. The immediate object of the meeting was to obtain further provision to meet the enormous amount of out-patient work. The claims of the institution were powerfully advocated by the chairman, by Dr. Andrew Clark and others, and it is to be hoped that the result of this effort will be to largely increase the means of usefulness of this valuable charity.

AT the last meeting of the Colchester Medical Society the following resolution was passed:—"This being the first meeting of the members of the Colchester Medical Society for the year 1881, they cannot help expressing their deep sorrow at the grave loss which they have sustained by the death of their hon. secretary, Mr. Edward Waylen. He was an intelligent and constant attendant at its meetings, a kind-hearted honourable man, a true and faithful friend, and a courteous and excellent secretary. This meeting begs to express its sympathy and condolence with his widow, to whom a copy of this resolution is now sent."

THE bazaar projected for the purpose of providing the funds necessary to meet the expenses of adding a new wing to the National Hospital for the Paralysed and Epileptic was opened on Tuesday at the Riding School, Albert Gate, by the Duchess of Wellington, in the absence of the Duchess of Edinburgh, who was prevented by her recent bereavement from attending. Several distinguished ladies assisted at the fair, and the sale, which was continued on the two following days, is likely to prove a success.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. Thomas Biggart, late of Baidlandhill, bequeathed £200 to the Western Infirmary, Glasgow. The late Colonel Gascoyne bequeathed £100 each to the Royal Hospital for Incurables and the National Hospital for the Paralysed and Epileptic. Mr. John Watt, late of Aberdeen, bequeathed the residue of his estate, in equal parts, to the Royal Infirmary and the Dispensary, Aberdeen. The will of Mr. Stephen Barron, late of Orsett-terrace, contains the following bequests: £4000 to St. Mary's Hospital, £2000 each to the Surrey County and the Brompton Consumption Hospitals, £1000 each to the Royal Hospital for Incurables, the Highgate Small-pox Hospital, the Great Northern Hospital, Ventnor Consumption Hospital, the Middlesex Hospital, Charing-cross Hospital, and the East London Hospital for Children. Surgeon-Major Newland, late of Carrickmines House, Co. Dublin, has bequeathed £1000 to Mercer's Hospital, £500 to the Hospital for Incurables, and £250 to the Medical Benevolent Fund Society of Ireland. The Misses Brooke have given £100 to the Adelaide Hospital, £50 to the Meath Hospital, and £50 to Coombe Lying-in Hospital, Dublin.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The tenth annual dinner of this Society was given on Tuesday evening in Willis's Rooms, Mr. Greenish, president, in the chair. The loyal toasts were warmly greeted, after which Mr. Schacht proposed "Science," to which Dr. Richardson replied. Dr. Broadbent acknowledged the toast of the "Medical Profession." Professor Abel gave "Prosperity to the Pharmaceutical Society," noticing with pleasure the efforts of the organisation to associate with an examination testing the private study of candidates for admission another that should give proof of a satisfactory curriculum of practical study. Mr. Greenish, responding, ascribed the progress of the pharmacy of Great Britain, which, he said, would compare favourably with that of any other country, to the work of this Society.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the lates*

ALMARAM, Mr. A., has been appointed Resident Clinical Assistant at the Hospital for Consumption and Diseases of the Chest, Brompton, vice Welch, resigned.

BALLANCE, C. A., L.R.C.P., M.R.C.S.E., L.S.A.L., has been appointed Senior Assistant House-Physician to St. Thomas's Hospital.

BERRY, W., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer and Public Vaccinator for the Twelfth District of the Wisbech Union.

BOLTON, R. E. N., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Ballickmoyler and Newtown Dispensary Districts of the Carlow Union.

BUCKLE, J., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Bardfield District of the Dunmow Union.

COLLIER, M. P. M., M.R.C.S.E., L.S.A.L., has been appointed Junior Assistant House-Physician to St. Thomas's Hospital.

CUMMING, G. W. H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Chipping Sodbury Union.

DICKSON, Mr. T. A., has been appointed House-Surgeon to the Glasgow Royal Infirmary.

DODDS, W. J., M.D., D.Sc., has been appointed Assistant Medical Officer to the Birmingham Borough Asylum.

DOUGLAS, G. C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Fourth District of the Ongar Union.

FOSTER, H. G., L.R.C.S.Ed., L.S.A.L., has been appointed Medical Officer of Health for the Swaffham (Norfolk) Rural Sanitary District, having previously been appointed Medical Officer of Health for the Wayland Rural Sanitary District, Civil Medical Examiner of Recruits for Regulars and Militia, and District Surgeon to the Great Eastern Railway, vice C. B. Wiles, resigned.

GRIFFIN, Dr. W., has been appointed Resident Clinical Assistant at the Hospital for Consumption and Diseases of the Chest, Brompton, vice Shearman, resigned.

HASLAM, W. F., M.R.C.S.E., L.S.A.L., has been appointed Resident Accoucheur to St. Thomas's Hospital.

HAYCROFT, Dr. B., has been appointed Professor of Physiology in Mason Science College, Birmingham.

HESLOP, T. P., M.D., F.R.C.P.L., J.P., has been appointed Consulting Physician to the Birmingham and Midland Skin and Lock Hospital.

HUDSON, G., M.D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Sixth District of the Beverley Union.

JONES, Mr. H., has been appointed House-Surgeon to the Glasgow Royal Infirmary.

JORDAN, F., F.R.C.S., has been appointed Consulting Surgeon to the Birmingham and Midland Skin and Lock Hospital.

LAMONT, J., M.A., B.Sc., M.B., C.M., has been appointed House-Surgeon to the Glasgow Royal Infirmary.

LAWRIE, Mr. W. J., has been appointed House-Physician to the Glasgow Royal Infirmary.

LEWIS, F. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the First District of the Llandovery Union.

LINDSAY, Mr. R. W., has been appointed House-Surgeon to the Glasgow Royal Infirmary.

LONG, J. P., L.R.C.S.I., L.A.H.D., has been reappointed Medical Officer for the East Deptford District of the Greenwich Union.

LOW, C. A., M.R.C.S.E., L.S.A.L., has been appointed a District Surgeon to the City of London Lying-in Hospital, vice W. Burton, resigned.

LUNN, J. R., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed Senior Resident Medical Officer to the new Marylebone Infirmary.

MCGEAGH, J. P., M.D., M.Ch., has been appointed Senior Assistant House-Surgeon to the Public Hospital and Dispensary, Sheffield.

MCLENNAN, Q., M.B., C.M., has been appointed House-Physician to the Glasgow Royal Infirmary.

MIDDLETON, W. H., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Visiting and Consulting Physician to the Mullingar Lunatic Asylum.

NOAKES, S. S., L.R.C.P.L., M.R.C.S.E., has been appointed Temporary Assistant Medical Officer to the County Asylum, Lancaster.

PEMBERTON, O., F.R.C.S., has been appointed Consulting Surgeon to the Birmingham and Midland Skin and Lock Hospital.

PEPPER, A. J., M.S., M.B., F.R.C.S., has been appointed Surgeon to the London Fever Hospital.

POTTS, J. A., M.B., M.R.C.S.E., has been appointed House-Surgeon to the Glasgow Royal Infirmary.

RAILTON, T. C., M.B., F.R.C.S.E., has been appointed Honorary Assistant Medical Officer of the Clinical Hospital, Cheetham-hill-road, Manchester.

READ, M., M.B., B.A., M.R.C.S.E., has been appointed Junior Resident Medical Officer at the Hospital for Sick Children, Great Ormond-street, vice F. G. D. Drewitt, M.B., M.A., M.R.C.P., resigned.

ROBERTS, N. E., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for No. 1 District of the Toxteth Union.

RUSSELL, J., M.D., F.R.C.P.L., J.P., has been appointed Consulting Physician to the Birmingham and Midland Skin and Lock Hospital.

SMITH, G., F.R.C.S.E., has been appointed Acting Surgeon to the Birmingham and Midland Skin and Lock Hospital.

SMITH, P., M.R.C.S.E., has been appointed Consulting Ophthalmic Surgeon to the Birmingham and Midland Skin and Lock Hospital.

SPICER, R. H. S., B.Sc., has been appointed Demonstrator of Comparative Anatomy and Botany at St. Mary's Hospital Medical School.

STEEL, Mr. R., has been appointed Clinical Assistant to the Glasgow Hospital and Dispensary for the Diseases of the Ear.

SUTTON, S. W., L.R.C.P., M.R.C.S.E., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

TAYLOR, J. W., F.R.C.S., has been appointed Acting Surgeon to the Birmingham and Midland Skin and Lock Hospital.

TREHERNE, F. H., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed a House-Surgeon to the West London Hospital, Hammersmith, vice D. G. L. Johnson, M.B., resigned.

WALKER, Mr. P. H., has been appointed House-Physician to the Glasgow Royal Infirmary.

WATSON, Mr. J. M., has been appointed House-Physician to the Glasgow Royal Infirmary.

WELFORD, C. H., M.B., C.M., has been appointed Senior House-Surgeon to the Sunderland Infirmary.

WHITEHOUSE, J., M.R.C.S.E., L.R.C.P.L., has been appointed Junior House-Surgeon to the Sunderland Infirmary.

WILLEY, C. H., M.B., M.R.C.S.E., has been appointed Junior House-Surgeon to the Borough Hospital, Birkenhead.

WILLIAMS, Mr. T. H., has been appointed House-Physician to the Glasgow Royal Infirmary.

WOODFORDE, W. T. G., M.D., has been reappointed Medical Officer of Health for the Berks Combined Sanitary Districts.

Births, Marriages, and Deaths.

BIRTHS.

BUSHELL.—On the 13th inst., at Edith-road, West Kensington, the wife of Dr. S. W. Bushell, Physician to H.B.M. Legation, Peking, of a son.

DALTON.—On the 12th inst., at Llandudno, the wife of Thomas Dalton, M.D., of a daughter.

GIBBONS.—On the 12th inst., at Cadogan-place, the wife of R. A Gibbons, M.D., of a son.

JAMISON.—On the 11th inst., at St. Helen's, Lancashire, the wife of Arthur Jamison, M.D., of a daughter.

ORWIN.—On the 10th inst., at Halifax, N.S., the wife of Surgeon-Major Orwin, Army Medical Department, of a son.

SANDILAND.—On the 14th inst., at 191, Southgate-road, N., the wife of A. H. Sandiland, M.R.C.S.E. & L.R.C.P.L., of a son.

SWANSON.—On the 13th inst., at Lawrence House, Yorks, the wife of George I. Swanson, M.D., of a son.

MARRIAGES.

ALLEN—MAW.—On the 11th inst., at St. Ann's Church, Bishop Auckland, R. G. Allen, L.R C.P., M.R.C.S.E., of Belper, to Annie Blythe Maw, of Bishop Auckland.

LITTLE—MELLOR.—On the 12th inst., at West-end Congregational Church, Southport, Joseph Henry Little, M.B., C.M., of Woolton, to Agnes Elisabeth, youngest daughter of Wright Mellor, Esq., J.P. and D.L., of Cote Royd, Huddersfield.

DEATHS.

BOND.—On the 13th inst., at Stoke Newington, Edward Thornley Bond, M.R.C.S.E., L.S.A.L., in his 84th year.

CARR.—On the 12th February, at Machanga, Central Africa, of tetanus, William Ward Carr, M.D., formerly of Lee, Kent, eldest son of the late William Carr, M.D., also of Lee, aged 34.

JAMESON.—On the 16th inst., at Oakwood Lodge, Upper Norwood, Hugh Jameson, F.R.C.S., Deputy Inspector-General of Hospitals and Fleets (Retired), in his 77th year.

SANDWITH.—On the 16th inst., at Avenue Friedland, Paris, Humphry Sandwith, M.D., C.B., D.C.L., late Colonial Secretary of Mauritius, and Author of "The Siege of Kars," aged 58.

SHERLOCK.—On the 13th inst., at Powyke, Worcester, after a short illness, James Sherlock, M.D., for twenty-seven years Medical Superintendent of the Worcester County and City Lunatic Asylum, aged 53.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, May 23.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Cantor Lectures: Mr. R. Brudenell Carter, "On Colour Blindness and its Influence upon various Industries."

Tuesday, May 24.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar, "On Non-Metallic Elements."

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Dr. Allen Thomson, "On some Bone Necklaces from the Andaman Islands."—Mr. E. H. Man, "On the Arts of the Andamanese and Nicobarese."—Mr. M. J. Walhouse, "On some Vestiges of Girl Sacrifices, Jar Burial, and Contracted Interments in India and the East."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Lawson Tait, "On Three Cases of Hepatotomy," and "On the Removal of the Uterine Appendages for the Arrest of Uterine Hæmorrhages."

Wednesday, May 25.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

Thursday, May 26.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Magnetism."

Friday, May 27.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—8 P.M. Professor H. E. Roscoe, "On Artificial Production of Indigo."

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Ordinary Meeting.

CLINICAL SOCIETY OF LONDON.—8½ P.M. Dr. Wiltshire, "On a Case of Traumatic Rupture of an Ovarian Cyst."—Dr. T. C. Fox, "On Two Cases of Chromidrosis, in which a Blue-black Pigment exuded upon the Skin of the Circum-orbital Regions."—Mr. MacCormac, "On a Case of Reunited Fracture of the Olecranon Process, in which bony union was obtained by Suture of the Bones."—Dr. Sturge and Mr. Godlee, "On a Sequel to a Case of Stretching of the Facial Nerve."

Saturday, May 28.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor C. E. Turner, "On Russian Literature: Lermontoff."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE Pass Examination for the diploma of Membership of the College was commenced on the 13th instant, when the following questions on Surgical Anatomy and the Principles and Practice of Surgery were submitted to the ninety-five candidates, who were required to answer at least four, including one of the first two, out of the six questions.

1. Describe the surfaces of the bones which enter into the formation of the wrist-joint and the synovial membrane.
2. Describe the relations of the popliteal artery.
3. What is the nature of the affection called ganglion? In what parts does it usually occur, and how would you treat it?
4. Describe the symptoms previous to an operation for hernia which would lead you to suspect mortification of a strangulated intestine, and the appearance during an operation which the intestine in such a state would present.
5. What cystic tumours commonly occur upon the surface of the head and face? How may they be distinguished from each other?
6. Give the usual causes and consequences of inflammation of the lymphatics of the arm.

The following were the questions on the Principles and Practice of Medicine:—

1. Enumerate and discuss the symptoms of hemiplegia and of paraplegia respectively, and point out the chief lesions to which these paralyses are due.
2. Describe the morbid anatomy of the lung in pulmonary phthisis; and give the clinical history of the disease.
3. What are the therapeutic uses of squill, ammoniacum, arsenic, and silver? What are the pharmacopœial preparations of these drugs, and what the composition and doses of these preparations? State the physiological effects, the medicinal uses, and the doses, of the dilute forms of hydrochloric, nitric, nitro-hydrochloric, sulphuric, and hydrocyanic acids.

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—English readers who are interested in this subject will find the original paper (part of which found its way into THE LANCET last week from a German source) in the *Boston Medical and Surgical Journal*, vol. cii., p. 471. Mr. Fignet's theory will, I have little doubt, share the fate of so many other theories which are based on insufficient data, and in ignorance of the "law of error" which pervades statistics of observations of complicated natural phenomena. He has had a "run of luck," as they say at Monaco, but by no means an extraordinary one, and it would be interesting to know if his "fortune" is still true to him. Mr. Darwin, in giving the relative proportions of the sexes in domesticated animals, observes of cattle ("The Descent of Man," 2nd edition, p. 246): "Of cattle I have received returns from nine gentlemen of 982 births, too few to be trusted; these consisted of 477 bull-calves and 505 cow-calves—i.e., in the proportion of 94·4 males to 100 females. The Rev. W. D. Fox informs me that in 1867, out of 34 calves born on a farm in Derbyshire only one was a bull." I have often discussed this question with the breeders of shorthorns and racehorses in my native county, and the Yorkshire breeders have the credit of being the most experienced breeders in England, and therefore, probably, in the world, and I never met one who had any confidence in his powers to determine the sexes of his horses or cattle, while all of them were satisfied with their ability to develop or eliminate other physical qualities to almost an unlimited extent.

I am, Sir, your obedient servant,
Bolton-row, Mayfair, May 9th, 1881. CHARLES ROBERTS.

RAILWAY SIGNAL-MEN.

IT is a disquieting consideration that the signal-men on railways are kept through long hours on duty in boxes sometimes a great distance from a station, but at points which are important to the safety of the traffic. An official of this class was recently found dead in his box. The engine-driver of a train found the danger signal on, and thus the occurrence was discovered in time to prevent an accident. Supposing he had found the "line-clear" signal on—which was quite as likely to happen—there would probably have been a serious accident. It is not to be expected that railway companies will see the need and wisdom of strengthening their staff so as to reduce the length of the hours on duty, and to establish a system of working in couples or of very frequent inspection; but the public may like to know the risks they run, and it is chiefly with a view to extend that information we, in common with our contemporaries, record the circumstance.

VACCINATION AND REVACCINATION.

To the Editor of THE LANCET.

SIR,—Can you give me some definite rules for the practice of revaccination? 1. At what age should revaccination first be practised? 2. If, on revaccination, a certain amount of irritation is produced for a few days at the punctures, but no distinct vesicle is formed, is this sufficient proof that the lymph has taken, but that the full course is aborted by previous protection? 3. Is one revaccination sufficient, or should it be repeated at intervals, and if so how frequently?

I am, Sir, yours obediently,
May 17th, 1881. M.R.C.S.

*** The rules of revaccination practised in this country are those adopted by the National Vaccine Establishment. Our correspondent should write to the secretary of the Local Government Board, Whitehall, and ask for a copy of the official memorandum on the subject. Here we may say briefly in respect to his questions—1. From fifteen to eighteen years of age, or, in immediate danger of small-pox, at twelve years of age. 2. "When persons who have once been efficiently vaccinated are, some years afterwards, revaccinated with effective lymph, there sometimes result vesicles which, as regards their course and that of the attendant areolæ, cannot be distinguished from the perfect results of primary vaccination. But far more usually the results are more or less modified by the influence of such previous vaccination. Often no true vesicles form, but merely papular elevations surrounded by areolæ; and these results, having attained their maximum on or before the fifth day, afterwards quickly decline. Or if vesicles form, their shape is apt to vary from that of the regular vesicle, and their course to be more rapid; so that their maturity is reached on or before the sixth day, their areolæ decline on or before the eighth day, and their scabbing begins correspondingly early. In either case the areolæ tend to diffuse themselves more widely and less regularly, and with more affection of the cellular membrane, than in primary vaccination; and the local changes are accompanied by much itching, often by some irritation of the axillary glands, and in some cases on the fourth or fifth day by considerable febrile disturbance."—(Gregory, revised by Ceely and Marson.) 3. In this country one efficient revaccination is held to be sufficient.—ED. L.

Mr. G. E. Pritchard.—1. Papers may be obtained from the College on application.—2. Bristowe, Guy and Ferrier, Farquharson, Ringer, Wilson, and Attfield.

C. K.—THE LANCET of Nov. 9th, 1878, and Jan. 9th, 1881.

CARBOLIC ACID IN THE TREATMENT OF WHOOPING-COUGH.

To the Editor of THE LANCET.

SIR,—I have read with interest Dr. Lee's papers upon whooping-cough, and am able to personally confirm his statements as to the efficacy of carbolic acid in the treatment of that disease. During last March I had been troubled with a cough. Early in April I found myself whooping in a most unmistakable manner; in fact, two medical friends voluntarily called my attention to the fact. Being the house-surgeon of a provincial infirmary, and constantly interviewing persons professionally, the desirability of taking a holiday was obvious to me.

Knowing the custom was very prevalent here of taking children to the gas-works when suffering from whooping-cough, the same idea occurred to me as to Dr. Lee as to what could possibly be the rationale of the benefit derived from the inhalation of gas-tar vapours. As I was daily in the habit of using the carbolic spray in the course of my professional duties, I made it a point of inhaling the spray for five minutes or so. On one day I had nineteen paroxysms of whooping; after three days of carbolic-acid treatment they were reduced to five. Since then I have quite recovered, never having taken medicine. No one fortunately took the affection, and I have had no need to absent myself. Judging from the effect upon myself, I think this treatment is worthy of trial. Doubtless if individual members of the profession will inquire into its value, we may ere long learn why and how it acts.

I am, Sir, yours faithfully,
Blackburn, May 7th, 1881. ROBERT H. FIRTH.

Medico.—We do not know to what new regulations our correspondent refers, as we have not seen any on the subject in the Army Circulars. If he will send us the date on which they were issued, we will look into the question.

The letter of *M. B.* on the lunacy question will appear in our next.

Vis Medicatrix had better consult our Students' number.

UTERINE DILATORS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 14th we notice a new "uterine dilator," by Dr. James, of Thurloe-square. Kindly allow us to say that we have made for some time past identical instruments for Dr. Chambers, who has been using them successfully in several cases. We can show the instruments to anyone who wishes to see them by calling, having several made for the demand we have had for them.

We are, Sir, your obedient servants,

May 19th, 1881. MAYER & MELTZER.

"THE LAWS OF THERAPY."

To the Editor of THE LANCET.

SIR,—Though I have tried my utmost to understand the position you have taken up, I must confess that I am unable to do so. I am quite aware that the term "allopathist" does not correctly describe the practice of the orthodox practitioner—far from it,—and I did not make use of the term, though it is pretty well understood to whom the term applies, and what it means. But when the homœopathists are charged with having "two sets of convictions," it is to be presumed that those who make the charge have one set, or that they are at all events diametrically opposed to one; the uninitiated public will think that such is the case, and that that is the reason why the homœopathist and the so-called allopathist cannot meet in consultation; and if this be not so, it seems to me to be as difficult to understand the standing of the modern orthodox practitioner as it evidently is for him to understand that of the modern homœopathist.

When, about fifteen years ago, I was in Edinburgh for a short time, I went to hear a clinical lecture by a certain celebrated professor of medicine at the university—it was not Dr. Henderson,—and I was very much struck by a remark he made, "that it was well always to have a theory of the action of the remedies used, and that it was better to make a theory for oneself, even though it should be a false one, rather than to have no theory at all." This teaching rather startled me then, but it showed me what I now believe is quite true, that every educated practitioner has or is searching for a theory of the action of the remedies he uses, and that he does not satisfy himself with using remedies simply to attain a certain result.

When I was studying in the London schools I was taught the "evacuating" theory, the theory of "*contraria contrariis curantur*," the "chemical" theory, and the true "allopathic" theory,—i.e., as I understood it, the medicinal treatment of a healthy organ with a view of relieving thereby an unhealthy organ of physiological sympathy; all these I could understand and appreciate, with the exception, perhaps, of the first; but I was not taught the theory of *similia similibus curantur*, and in this respect I venture to think my medical education was very defective.

It certainly is not by any of the first four of these theories that the action of small doses of ipecacuanha, or Dover's powder, or picrotoxin, in the respective cases alluded to can be explained.

Dr. Murrell, in his very valuable remarks in the *Practitioner* on the use of Dover's powder and similar drugs in the treatment of the night sweating of phthisis, makes the following significant statement:—"It is a noteworthy fact that pathological sweating may be arrested not only by drugs that exert an inhibitory action on the sweat centres, but also by agents that in health promote perspiration." And, again, "Seeing that pathological sweating might be arrested by Dover's powder, an agent extensively employed as a diaphoretic, I determined to turn my attention to other sweat excitors." This very valuable indication led him to try several remedies in a manner which before a very recent period would have been thought of as being anything but orthodox. No arrangement of words can do away with the plain fact that there is here an application, which we can thoroughly appreciate, of a very useful rule.

I think myself that it will be found to be true that *all* drugs act on apparently opposite lines in larger and smaller doses, but I was not aware that this was recognised as a well-known fact. Nothing can be clearer than this, that Dr. Murrell did not perceive this as a universal law when he made his experiments some two or three years ago, but that he was led by the fact that in one case an agent which in health promoted perspiration arrested it in disease, to try other similar agencies; had he recognised a law, what need to mention one case as a warrant for a similar trial? Whenever we apply the law of gravitation we do not quote the fall of Newton's apple, or some similar illustration. No; it appears to me that all we *know* at present is that some few drugs act on apparently opposite lines in larger and smaller doses, and that we may only infer that what is true of some is true of all. Until this is clearly made out, it is only the formula of *similia similibus* which can help us to work out the problem in our dealing with disease, for we have only to know the action of the larger dose of a certain drug, which can always be ascertained by experiment in health, and to find it similar to the manifestations of disease, and we have it in our power to find out whether it will cure the disease or arrest its action by the use of the smaller dose of the same drug. This is what Dr. Murrell did with much success; and if it be, indeed, a well-known *law* of therapy that *all* drugs act on apparently opposite lines in large and small doses, many more orthodox practitioners will do likewise. It is, however, nothing more nor less than homœopathy, and homœopathy "pure and simple."

It was the neglect, nay, rather the repudiation, of this formula by the majority of practitioners which brought about a homœopathic sect, and there can be no doubt that when the beauty and simplicity and trustworthiness of this rule are more generally appreciated by the profession, homœopathy as a system will die out. The truth will be absorbed, and the name expire. While this is taking place, as it is undoubtedly now doing, would it not be better to try to heal divisions than to open up prejudices based on past misunderstandings?

I am, Sir, yours truly,

Scarborough, May 14th, 1881. F. FLINT, M.D.

To the Editor of THE LANCET.

SIR,—I thank you for your courteous reply to my note. You are quite justified in wondering at my ignorance, for it is quite true that I did not know "that *all* drugs act differently—and, as it may seem to the unscientific, on totally opposite lines—in different doses." But if that is the case—and far be it from me to deny it—then it would follow that the true therapeutic rule is to select for a case of disease a remedy that in one dose, say a large dose, will produce a morbid state similar to that disease, and administer it in another, say a small dose, which, according to your "universal law of therapy," will produce what "may seem to the unscientific" a totally opposite state. Thus in a case of vomiting from stomach derangement we should give, in a small dose, a medicine that is capable of causing, in a large dose, the stomach derangement that produces vomiting, and the opposite state—viz., cessation of the vomiting and restoration of the stomach to its normal state will ensue. But this is just the homœopathic therapeutic rule, so that, at all events, "the universal law of therapy" is not antagonistic, but, on the contrary, favourable to the homœopathic therapeutic rule. This rule is, I must repeat, no explanation of the *modus operandi* of medicines in disease; it is merely a rule for the solution of the remedy. "*Similia similibus curentur*" (not *curantur*, as your printer insists on making it), "let likes be treated by likes," not "like cures like," which would require quite other Latin.—I am, Sir, your obedient servant,

London, May 13th, 1881. R. E. DUDGEON.

CONCURRENT VARIOLA AND VACCINIA.

To the Editor of THE LANCET.

SIR,—Your correspondent, "In Perplexity," in your issue of last week, need not go out of his way to theorise about "worn-out lymph," as facts, which appear to be well-known to experienced vaccinators, are quite sufficient to explain the case. The protective areola in vaccinia is not complete till the ninth or tenth day in primary vaccination, but one or two days earlier (seventh or eighth) in secondary vaccination. The eruption of confluent variola is generally stated to appear on the third day after invasion, therefore in this case invasion took place on May 2nd, and at this date the variola had spread throughout his entire system, as shown by the constitutional signs of invasion, while the vaccinia (assuming it to have been a case of revaccination) was little more than local, being only at its sixth day, at least one day short of the time required for complete protection. It is probable, however, even in this case that the abundant eruption would subside, and not be accompanied by severe symptoms at maturation; and it is to be hoped that "In Perplexity" will give us the further history of the case. It would also be interesting to hear whether it was a case of vaccination or of revaccination.—I am, Sir, yours truly,

Torquay, May 16th, 1881. M.B.

To the Editor of THE LANCET.

SIR,—In the year 1870 I revaccinated two young ladies, sisters. I am unable just now to refer to the exact dates, but they were both vaccinated on a Thursday, and on the next Thursday I called to see the result. The younger sister's arm showed the operation to have been abortive, but the elder sister's was like a first vaccination.

On the Saturday following the inspection I was sent for to see the elder sister, who was said to be very ill. I found her in a high state of fever, and racked with pain in every joint. The next day (Sunday) the eruption of small-pox appeared, entirely covering the body, and she soon became almost one confluent mass. The case appeared to me to be nearly hopeless, when on the Friday the vesicles began to dry up. There was no secondary fever, no purulent stage, and the patient got rapidly well.

This case in its onset closely resembles the one given by "Perplexity" in this week's LANCET, and I should be glad if your correspondent will give the termination of his case, to see if there be an equal resemblance at the finish. I am, Sir, yours obediently,

Lechlade, May 16th, 1881. W. H. BOX.

To the Editor of THE LANCET.

SIR,—Had "In Perplexity" consulted section 86 of the "Medical Digest" he would have seen that the co-existence of vaccinia and variola was by no means unusual.—I am, Sir, yours, &c.,

May 19th, 1881. RICHARD NEALE, M.D. Lond.

A JAPANESE PHARMACOPŒIA.

THE Japanese Government having some years ago issued regulations for the examination of candidates for a licence to engage in practice as apothecaries, have supplemented that step by deciding to establish a standard pharmacopœia. A special commission charged with the duty of compiling the work has been appointed, and has commenced its labours. Hitherto, it appears, English, American, Dutch, and other pharmacopœias have been in use in Japan.

THE CASE OF CHRISTINA MARSHALL.

To the Editor of THE LANCET.

SIR,—I am glad to be able to report a favourable and timely change in this case. Towards the end of last week the girl became less apathetic. On Sunday last she took two teaspoonfuls of milk; on Monday a little cream every three hours; on Tuesday a few grapes and some beef-tea and milk; and this was repeated on Wednesday. Her pulse is now 64 and of better calibre, and she expresses herself as feeling a little improvement in her condition.

I am, Sir, yours truly,
JAMES DOUGAL.
Bolton, May 12th, 1881.

THE NATIONAL VACCINE ESTABLISHMENT AND ITS LYMPH.

To the Editor of THE LANCET.

SIR,—Permit me to thank "Public Vaccinator" for calling attention to the quality of the lymph supplied by the National Vaccine Establishment, and to express a wish that his appeal to the profession on the subject may receive a hearty response in your columns; for myself, I am sorry to state that my experience is in perfect accord with his own. I have on several occasions been supplied with lymph from that establishment which was nearly inert, and out of the total number vaccinated from a recent supply, there was but one successful case, if a single vesicle appearing and maturing six or seven days later than the usual course may be termed "successful." Being called to meet a neighbouring practitioner, who is also a public vaccinator, about that time, I took the opportunity of asking him his experience on the same subject, and he informed me that he had for some time given up sending for lymph to the National Vaccine Establishment owing to his want of success with it, and now preferred paying for it to a wholesale house which supplied it, and that the lymph he had so obtained had so far given him every satisfaction.

I am, Sir, truly yours,
P. V., No. 2.
May 14th, 1881.

To the Editor of THE LANCET.

SIR,—In answer to the letter of "Public Vaccinator" in this day's LANCET, I beg to inform him that I had a supply of lymph from the National Vaccine Establishment. I vaccinated four children with it on April 4th; three failed, and in the fourth case the vesicles came forward too soon, so that when brought for inspection there was no lymph to be had. As I had relied on these cases for a supply, I had to fall back on some points charged in October and kept in a half ounce bottle, and these cases were almost all successful. I think the National vaccine lymph is not so good as it used to be, for formerly I very seldom had an unsuccessful case.—I am, Sir, yours, &c.,

Bucks, May 14th, 1881. ANOTHER PUBLIC VACCINATOR.

To the Editor of THE LANCET.

SIR,—In reply to "A Public Vaccinator" in your last issue, I may say that about a fortnight ago I obtained from the National Vaccine Establishment two tubes of lymph, with which I operated on ten infants without being successful in a single instance. On reference to my register, I find that during the past two years the proportion of my unsuccessful cases has been 1 per cent., and, curiously enough, in each of the unsuccessful cases lymph from the National Vaccine Establishment was used.—I am, Sir, yours obediently,

Lewes, May 16th, 1881. ANOTHER PUBLIC VACCINATOR.

Clinical Lecture

ON

CASES OF ANOMALOUS RHEUMATIC FEVER.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.,

PHYSICIAN TO ST. MARY'S HOSPITAL.

Gentlemen,—I call your attention to-day to some cases which I think are very important subjects of study. I designate them "anomalous" rheumatism because they differed very materially in their progress from ordinary examples of that malady. Their course was not even (not ὁμαλος), but irregular. Diseases have mostly a form and course which they observe—a norm of their own,—and deviations from it bode no good. So long as the symptoms follow the usual and orderly evolution, though they may be severe and even perilous, we are not at fault—we know what to expect and how to act; but when unusual and strange symptoms arise, when danger threatens, now from one quarter and then from another, we are prone to get perplexed and lose our heads. Articular rheumatism, though severe, confined to the joints, or with but moderate cardiac complication, is a tolerably straightforward matter; but rheumatic fever with little joint affection, and much delirium, hyperpyrexia, or lung œdema, is quite a different thing.

Case 1. *Articular rheumatism of small amount; more prominent pericardial, pleuritic, pulmonary, and intestinal inflammatory disorder; morbilloid eruption copiously developed, followed by sudamina, some delirium, persistent hyperpyrexia.*—A. S——, aged thirteen, errand-boy, was admitted on Dec. 17th, 1880. His mother died of phthisis, and one brother also; another, aged four, died of measles; two sisters are living, one of whom is weak. Three months ago he was struck by a stone over the left eye, and has never been well since. Had always been delicate, but never had any special illness. On Dec. 7th he felt unwell, and on the 10th he had to leave his work, complaining of pain in his limbs and in his right side. On the 13th he had pain in the back; he gradually grew worse, and was admitted into hospital. He is a thin, weakly-looking boy; his feet and hands are swollen and painful, and pericardial friction is heard. Dulness on left side extends from third space to sixth rib, and from mid-sternum to apex, which is situated in fourth space outside vertical nipple-line. Dulness in first left space is less absolute than in the second and third. Sternum is dull up to about level of the second rib; laterally dulness extends to about right edge of sternum, and to the left about half an inch beyond right nipple line. Harsh, grating friction sound heard from the level of the second space down to the fifth rib; is less distinct below than higher up; it is well heard in upper left front. Breathing in upper left front is harsh and imperfect; in the lower left back breathing is harsh, and rather weak, attended with crepitation and rhonchus; in the upper left back the breathing is better; the right back in the same state as the left. He lies on the right side; heart's impulse better seen than felt; abdomen moves very little in respiration; area of hepatic dulness normal; no splenic enlargement.—19th: Delirious all night, getting out of bed; takes plenty of nourishment, milk, and beef-tea; lower ribs move well; pulse 114, soft; bowels open four times, the stools very light-coloured; no spots. To take five grains of salicylate of soda, four minims of sedative solution of opium, and an ounce and a half of chloroform water, every four hours; five grains of chloral, ten grains of bromide of potassium, and an ounce of camphor mixture, every night.—20th: Had two doses of the sedative; slept much better, and had less delirium.—23rd: Pulse 116, soft; respiration 33; lies down well. The icebag to præcordia ordered on the 21st is continued; he likes it; it is applied a good deal. Friction sound still evident; dulness extends nearly to the top of the sternum; tongue red and moist, coated. He complains of pain across chest and belly, which latter is large and tympanitic, and moves but little. Urine red, thick, loaded with lithates, sp. gr. 1032, contains albumen. Cardiac impulse is felt most distinctly in fourth space. At midnight, being very restless and wandering, in spite of half a grain of opium every four hours, and the temperature being 104·5°, he had fifteen grains of quinine. At 2 A.M. the temperature fell to 102°; at 4 A.M. it rose to 104°; at 6 A.M. fell to 101°, and at 8 A.M. to 99°. He slept better after the quinine. On the night of the 22nd he had two enemata of fifteen minims of tincture of opium on account of diarrhœa and wandering.—26th: At 2.30 P.M. the pulse was 114; temperature 101°; respiration 28; was delirious in the night, but takes nourishment well; has pain across the chest. Had much diarrhœa after fifteen grains of salicylate of soda every hour (six times last evening). Quinine repeated at 11 P.M.; tongue very dry and red; sternum resonant down to the third rib, left front also more resonant; urine pretty copious. To take five grains of disulphate of quinine every four hours; four ounces of brandy; continue opium pill every four hours.—28th: Slept well during last night; eyelids swollen and puffy, and nose also; a rash has appeared on chest, neck, shoulder, and upper arms, scarcely seen on abdomen or lower limbs, absent from face; it is of a dull red colour, consists of spots and short streaks, tending to coalesce, scarcely elevated, with interspaces of natural colour. Abdomen large; bowels open twice; stools loose, but not so loose as they have been. Heart's apex beats in fifth space well within vertical nipple-line; no murmur; sounds well heard at fifth space. Shrill tube-sounds of small size, inspiratory and expiratory, over all left front, much less marked in right front, where air enters well, producing vesicular murmur. In the right back there is extensive dulness, occupying more than the lower two-thirds of the back; in this region the entry of air is very weak, and scarcely anything is heard but muco-crepitant râles. In the left back dulness is less extensive; air enters tolerably at upper fourth, but very defectively in lower half, where numerous crepitations are heard. Urine in fair quantity, clear, not albuminous. Ice-bag applied pretty regularly until to-day, when it was omitted.—29th: Last evening, the temperature being 105°, at 8 o'clock and at 10 he had a bath cooled down with ice. The temperature fell to 101° before he left it; rash quite disappeared. The temperature at 11.30 P.M. was 100·2°; pulse 112; respiration, which before the bath was about 40 and laboured, fell to about 30, and was much easier. At 2 A.M. (29th), the temperature having reached 105·6°, he had a second bath, after which the temperature fell to 98·8° at 4 A.M. The rash at 6 A.M. was a very bright red, and all over the face. At 2.30 P.M. he was quite rational; pulse 110. The rash was visible on the thighs, as a rather faint flush in some parts, in others as a mottling. A third bath was given at this time. The temperature, which was 104·6° before the taking of the bath, soon after fell to 100°. Pulse 120, small and weak. At 3.10 P.M. the temperature was 97°.—31st: Friction-sound ceased; sternal dulness commences at about third cartilage; in left front the third space is dull, the second half resonant, and the first quite. Pulse 102, distinct. Weak entry of air in all the right back; a good many small, incomplete crepitations are heard. In the left back air enters more freely, and crepitations are more developed. Night bad. No bath since 10 A.M. of 30th. One grain of opium at bed-time.

Jan. 1st, 1881: Has had more hyperpyrexia; three baths have been given; he was very restless and thirsty before; shivered very much after the first bath, and was very prostrate; had to be removed soon from bath and take brandy. Subsequently cold sponging was had recourse to, when the temperature ran high; opium did not quiet him, but he slept after the bath. Eruption gone; tongue very dry. No deafness. Pulse 110, distinct; respiration 45. Air enters, but imperfectly, in both backs, especially at lower parts; some dulness near bases; some sickness. Omit the quinine.—4th: Slept well with fifteen minims of tincture of opium in enema at eight P.M. last evening; was extremely restless before. Pulse 130, weak. Takes food well. Lower ribs expand well. Yesterday air entered well in both backs, producing numerous crepitations; no murmurs. Has several red papules, much larger and more raised than those of typhoid, at left iliac region, and a few elsewhere. A bedsore threatens to form on left hip. Only one bath given since the 1st. Rheumatism is reappearing in some of his joints. Half a grain of opium given as circumstances require. 7th: Is very thirsty when restless fits come on; a copious crop of sudamina on chest. Pulse 108, distinct. Large intestine much distended; belly large. Bowels open twice; perspires very freely. Feet are swollen and painful; he cannot bear to have them moved. One grain of calomel to be given at night, five grains of Dover's powder, and half an ounce of acetate of ammonia mixture three times a day.—9th: Previous night rather restless, though he had opiate enema. Ordered ten grains of disulphate of quinine to be taken at 6 P.M., and again at 7 P.M. About 9.30 P.M. he had a rigor, and was very sick and vomited, and bowels acted in bed. Face flushed; no headache. Respiration 42, moans; pulse 135, rapid and running. Picks his nose constantly. Has been very restless and excitable all the evening; complains of constant pain in dorsal region of back, and holds himself rigidly. No pains in joints; mind quite clear at present; belly very tympanitic; trunk covered with sudamina; pupils natural. Temperature 105°. Sponging. Fifteen minims of tincture of digitalis, three grains of carbonate of ammonia to half an ounce of water every four hours.—10th: Omit mixture, add fifteen minims of tincture of digitalis to each dose of acetate of ammonia mixture, with Dover's powder.—13th: Pulse 100; temperature normal. Bowels loose; stools fully bilious.—15th: Makes a miserable whining noise all night long, disturbing the other patients. Takes food very well. Tongue and mouth clean; pulse 96. Fifteen minims of tincture of digitalis, three grains of carbonate of ammonia, one drachm of tincture of cinchona, and one ounce of the decoction of cinchona three times a day.—19th: Slept much better, better than he has yet. Much pain on movement. Takes food well. Has a bedsore at bottom of sacral region; it commenced as an angry pimple, which he picked, so he has others, but only this has come to a sore. The next day there was a deep hole, exposing a sacral spine, where the bone was felt denuded. He was ordered to be kept lying on his face, and the wound to be dressed with carbolic lotion under oil silk and tenax.—26th: Sore stationary. Bowels very irritable, act after any ingesta two or three times in an hour, then become quiet again for some time. Gets irritable and restless at times; would have no sleep but for subcutaneous morphia. He was ordered five grains of oxide of zinc and one quarter of a grain of opium four times a day. This did not succeed in quieting the bowels; sickness came on, and after two or three days the powders were omitted. On Jan. 31st he was ordered one drachm of malt extract, with cod-liver oil.

On Feb. 3rd the digitalis mixture was omitted.—15th: He is very much improved, the sore on sacrum is all but healed; the denuded bone seems covered. He is much more cheerful, but becomes restless and very thirsty at night occasionally, drinks copiously, then becomes quiet and sleeps. He has not had an attack of this kind for a week until last night.

[6] From this date the temperature is only given when it reached 100°. Observations made bi-horally till Jan. 21st.

[7] Three observations.

[8] Five observations.

[9] Four observations.

March 9th. — The temperature has remained normal or nearly so ever since, but has not been taken at midnight. The only exceptions have been on Feb. 15th and 16th, when it ranged about 100°; and on Feb. 23rd it marked 100·4°. On March 16th and 17th the temperature was taken three times during the night, and was found normal.

March 14th: Going on very well; has gained much flesh; walks about.

(To be concluded.)

NOTES ON THE

SYSTEMATIC TREATMENT OF NERVE PROSTRATION AND HYSTERIA CONNECTED WITH UTERINE DISEASE.

BY W. S. PLAYFAIR, M.D., F.R.C.P.,
PROFESSOR OF OBSTETRIC MEDICINE IN KING'S COLLEGE AND PHYSICIAN FOR THE DISEASES OF WOMEN AND CHILDREN TO KING'S COLLEGE HOSPITAL.

I AM anxious to bring very briefly under the notice of the profession in England a method of dealing with certain grave and most intractable forms of nervous disorder familiar to all who see much of the diseases of women, which I first became acquainted with through the study of a remarkable and interesting little work by Dr. Weir Mitchell of Philadelphia, entitled "Fat and Blood, and how to make them." In doing so I have no original contribution to medical science to make; I have simply followed Dr. Mitchell's directions, but with results so astonishing and satisfactory to myself, in cases which were quite heart-breaking from their obstinate resistance to all ordinary management, that I am confident I shall be doing the profession a service if I can secure for Dr. Mitchell's plan, which is based on sound theory and accurate clinical observation, a more extended trial than it has as yet received. I am the more encouraged to do this since Dr. Mitchell informs me that he is not aware that his principles of management have hitherto been tried at all in England, although well known in America. "Here," he writes to me, "the treatment has rescued hundreds of women, and is used by men like Perry and Goodell with increasing confidence. I hope at some time to write for some English journal a *résumé* of the treatment, but it were far better done by one like you, who could quote cases of success in England."

Pending Dr. Mitchell's promised contribution, which will, I am sure, be read with interest, I may, at least, try to prepare the way by the recital of a few of the cases in which I have found his plan so useful.

The class of cases referred to is not easy to define or describe accurately, and yet they must be perfectly familiar to all. I have called the condition, in the heading to these notes, "Nerve Prostration and Hysteria connected with Uterine Disease." Goodell, who has an interesting chapter on the subject in his "Lessons on Gynæcology," heads it, "Nerve-tire, or the Relations of Neurasthenia to Diseases of the Womb." The protean symptoms we have to deal with are such as gradually develop themselves in those confirmed invalids who are so widely scattered over the country, who have been from one doctor to another, subjected to all sorts of uterine medication, mechanical and other, with no lasting improvement, until eventually they become bedridden, or nearly so, sleepless, victims to chloral and morphia, worn and wasted, and burdens to themselves and their families. Now, in a large number of these cases there is, or has been, very real uterine mischief. I shall not be accused, I am sure, of any disposition to minimise the influence of local uterine disorder on the general health. As a matter of fact, however, many of these cases have drifted far beyond the point at which local treatment, however judicious, is capable of effecting a cure. The pain, the backache, the leucorrhœa, the difficulty in progression, the disordered menstruation which are attendants on the local troubles, have ended in producing a state of general disturbance in which all the bodily functions become implicated. The nervous system is profoundly affected, the blood impoverished, and the general nutrition at the lowest ebb.

I shall not attempt here to explain the pathology of this state, but rather to describe the class of case, which, however, all my readers will at once recognise. Such cases have two or three prominent symptoms in common, among the most marked of which are wasting of the fatty tissues, combined with anæmia, the patient having gradually lost all appetite, professing a total inability to take a healthy amount of food, and often consuming barely enough to support vitality. Associated with this are very marked dyspeptic symptoms, too often aggravated by the pernicious habit of deadening pain by chloral, morphia, or stimulants. As a necessary consequence of such a state, and partly no doubt from local pain, all exercise is abandoned, and the patient becomes entirely confined to the house, or even to bed. Another group of symptoms which soon show themselves under such conditions are those of a moral character, the patient becoming emotional and hysterical, constantly craving for sympathy, which she often obtains to a degree most prejudicial to her welfare, until at last the whole household becomes victimised by the morbid selfishness thus developed. Every practitioner must know of cases of this kind, and must be familiar with the useless endeavours at cure which have been made by tonics, water cure, and a hundred other plans, each of which has proved equally unsuccessful.

It is in such cases that Dr. Mitchell's method is applicable, and it is based on the principle, which must be admitted to be perfectly physiological and reasonable, of removing the patient from the unwholesome moral atmosphere in which she has been living, combined with the renewal of her vitality by excessive feeding, which, under ordinary circumstances, could not be assimilated, but which is rendered possible by passive muscular exercise obtained through the systematic use of shampooing and electricity. At first sight this sounds, perhaps, chimerical; and, had I not myself witnessed the astonishing success which followed its use, I would doubtless be as sceptical as others may be as to its value. I propose, however, to relate the first four cases in which I have followed Dr. Mitchell's method, each of which had been for years in a state of hopeless misery, subjected to all sorts of treatment in vain, and I trust that the simple narration of these remarkable cases, which are not selected, but are the first which have come under my observation, may secure for this rational treatment a fair and extended trial. Before relating them, however, I shall shortly describe the method of treatment I used, and in doing this I merely paraphrase Dr. Mitchell's directions. I must necessarily be extremely brief, and I must refer those who are disposed to try it to Dr. Mitchell's book, in which full details for their guidance will be found. The plan involves four principal heads, each of which I shall refer to separately.

1. *Seclusion and rest.*—An important element in the treatment, and one which, from what I have seen of these cases, I believe to be absolutely indispensable, is the entire seclusion of the patient under a competent nurse, and her removal from the morbid atmosphere of invalid habits, which has gradually grown up around her. Unless the patient is entirely removed from the injudicious sympathy and constant tending of her friends, it will be next to impossible to gain that moral influence over her which is really essential to success. This is a point which involves so severe a strain that it may be found very difficult to obtain the consent of the patient and her friends to a measure which will seem to them so harsh and strange. I do not think, however, that any compromise on this point should be admitted, and if it be found impossible, from domestic reasons, to secure the removal of the patient from her house, it should, at least, be made an absolute *sine quâ non* that she should be placed in a separate room with her nurse, and that she should not be visited by any one except her medical attendant. On this point Dr. Mitchell's experience is worthy of note. "I have often," he says, "made the effort to treat these cases in their own homes, and to isolate them there, but I have rarely done so without promising that I would not again complicate my treatment by such embarrassments. Once separate the patient from the moral and physical surroundings which have become part of her life of sickness, and you will have made a change which will be, of itself, beneficial, and will enormously aid in the treatment which is to follow." The first step, on commencing, is to place the patient at rest in bed. It will readily be understood that this absolute repose is only intended as a temporary resource, until, by the means presently to be described, the nutrition is improved, and new tissues are built up. Space will not permit of my following Dr. Mitchell in his explanation of the manner in which this proves serviceable; but, independently of the physical benefit in patients apt to suffer from exhaustion on the slightest fatigue, there is a distinct moral gain. "From a life of irregular hours, and probably endless drugging, from hurtful sympathy and over-zealous care, the patient passes to an atmosphere of quiet, to order and control, to the system and care of a thorough nurse, to an absence of drugs, and to simple diet." As a rule, in bad cases this repose in bed is continued during the greater part of the treatment, averaging from six to eight weeks; and at first the rest is made absolute, the patient being only allowed to rise for the purpose of passing her evacuations, and is neither allowed to read, to sew, nor to feed herself. Practically there is so much to do with feeding, massage, and electricity, that this is not found so wearisome as might be supposed; but, no doubt, the monotony of the life and the growing strength, which accompanies a satisfactory progress towards cure, tend to make the patient the more willing to throw off her old habits of invalidism when the proper time arrives to make the effort. By degrees the period of repose is lessened, and the patient is gradually made to sit up for several hours, until towards the end of the cure she only rests on the bed for three or four hours daily.

2. *Massage.*—This, combined with faradisation, is a very important part of the treatment, and it consists in systematic shampooing and exercise of all the muscles, both of the extremities and trunk, first for half an hour or so twice daily, but very soon for not less than an hour and a half night and morning. By this means the cutaneous circulation is improved, and the muscles are brought into active exercise without the expenditure of nerve force. To do this effectually considerable experience is required, and although in one or two cases I have had it done successfully by the nurse, it requires so much intelligence on her part, and she is besides otherwise so fully occupied by the rest of her work, that I think it preferable to employ a regular rubber. Full details of the method to be adopted, and the best way of exercising the various groups of muscles and the joints will be found in Dr. Mitchell's book. It is surprising how soon the patient comes positively to enjoy a manipulation that for the first few days is very trying. Soon all local tenderness disappears, and a pleasant sense of exhaustion, followed by refreshing sleep, is alone experienced. In two of my cases the abdomen, especially in the ovarian regions, was so tender that the patient at first shrank from the slightest touch, but in a very short time she could be freely handled and kneaded in every part.

3. *Electricity.*—This forms a valuable subsidiary means of exercising the muscles. The interrupted current is employed twice daily from half to three-quarters of an hour. Here, again, some practical skill is necessary, but with a little careful teaching on the part of the practitioner, the use of the battery can be safely and efficiently entrusted to the nurse. The poles, armed with wetted sponges, are placed on the muscles to be operated on in turn, about four inches apart, and slowly moved until the muscle is fully and freely contracted. Commencing with the feet, the whole body, except the head, is thus systematically gone over. There is no doubt that this is painful and disagreeable, but it is of unquestionable utility, especially in cases such as the one to be presently narrated, in which there was long-standing hysterical paralysis, and consequent atrophy from disuse of extensive groups of muscles.

4. *Diet and regimen.*—These form the most important and most characteristic part of the cure. It is perfectly astonishing how, under the conditions above described, a pale, anæmic, and wasted invalid, able to eat next to no food, can be brought to consume, and not only to consume but perfectly to assimilate, an amount of nourishment that would appear to be incredible had experience not amply

proved the fact, so that she shall gain flesh, weight, and strength so rapidly that the change is almost apparent to the eye from day to day. The first step, after secluding the patient with the nurse, and before the massage is commenced, is to place her on a diet of milk alone, given at intervals of three hours. At first three to four ounces are given at each feeding, but in a couple of days or so the amount is increased to eight or ten ounces, so that within three or four days she is consuming two to three quarts of milk within the twenty-four hours. No difficulty is experienced in getting the patient to take this quantity, and if she suffers, as so many of these cases do, from dyspeptic symptoms, they rapidly disappear. After the first two days, when the stomach is settled, the massage is commenced, and along with it an increased amount of food is administered, commencing with bread-and-butter, an egg, or the like, for breakfast; then, in a day or two, a chop finely cut up, with some vegetables, is given at midday, and so on progressively, until in from ten days to a fortnight three full meals daily are given, besides from a quart to two quarts of milk in divided quantities, and a considerable amount of soup made from raw beef, after a receipt given in Dr. Mitchell's book. It seems impossible, but it is nevertheless a fact, that under the use of massage and electricity these large amounts of food are taken readily without the slightest feeling of dyspepsia or discomfort. In illustration I copy the food journal on the fourteenth day of treatment of one of my patients, who had been bedridden for many years, and who all that time had existed on a dietary almost as remarkable from its smallness, frequently not taking more than half a tumbler of milk in twenty-four hours, and who could not be persuaded to eat more than one strawberry at a time, as forming a meal too large for her capacity. The treatment was commenced on October 16th with three ounces of milk every third hour. On Oct. 30th this was what she consumed with appetite:—5 A.M.: Ten ounces of raw meat soup.—8 A.M.: Cup of black coffee.—9 A.M.: Plate of oatmeal porridge with a gill of cream and a tumbler of milk.—12.30: Milk.—1.45 P.M.: Whiting, bread-and-butter, rumpsteak, cauliflower, omelette, and a tumbler of milk.—4 P.M.: Milk.—5 P.M.: Milk and bread-and-butter.—7 P.M.: Fried haddock, chicken, cauliflower, apple and cream, and a glass of burgundy.—9.30: Milk.—11 P.M: Raw meat soup. (The milk between 8 A.M. and 9.30 P.M. amounted to two quarts.) Nor is this exceptional. In every case I have treated on this plan similar amounts of food were taken, and with the same advantage. Of course, certain difficulties are apt to be met with, but only in one of my cases was any nausea or oppression experienced from the administration of this apparently excessive diet, and in that I attributed the sickness rather to too sudden an attempt to stop the hypodermic injection of morphia the patient had been accustomed to than to the feeding. At any rate, should sickness supervene, a temporary return to milk alone for a day or two will be sufficient to settle the stomach.

I have only attempted to sketch, in very rough outline, the principles on which the treatment is conducted; the results will be better appreciated by a short narration of a few of the cases in which I have employed it with success.

CASE 1.—Early in October of last year I was asked to see a lady thirty-two years of age, with the following history: She had been married at the age of twenty-two, and since the birth of her last child had suffered much from various uterine troubles, described to me by her medical attendant as "ulceration, perimetritis, and endometritis." Shortly after the death of her husband, in 1876, these culminated in a pelvic abscess, which opened first through the bladder and afterwards through the vagina. Paralysis of the bladder immediately followed the appearance of pus in the urine, and from that time the urine was never spontaneously voided, and the catheter was always used. Soon after this she began to lose power in the right leg and then in the left, until they both became completely paralysed, so that she could not even move her toes, and lay on her back with her legs slightly drawn up, the muscles being much wasted. Towards the end of 1877, after some pain in the back of her neck and twitching of the muscles, she began to lose power in her left arm and in her neck, so that she lay absolutely immobile in bed, the only part of her body she was able to move at all being her right arm. Up to this time the pelvic abscess had continued to discharge through the vagina, and occasionally through the bladder, but it now ceased to do so, and there were no further symptoms referable to the uterine organs. Her general condition, however, remained unaltered, in spite of the most judicious medical treatment. She was seen, from time to time, by several of our most eminent consultants, all of whom recognised the probable hysterical character of her illness, but none of the remedies employed had any beneficial effect. There was almost total anorexia, the amount of food consumed was absurdly small, and the necessary consequence of this inability to take food, combined with four years in bed with paralysis of the greater part of the body, and the habitual use of chloral to induce sleep, had reduced a naturally fine woman to a mere shadow. In October, 1880, her medical attendant was good enough to bring her to London for the purpose of giving a fair trial to the Weir Mitchell method of treatment, with the ready co-operation of herself and her friends, and she was conveyed on a couch slung from the roof of a saloon carriage, so as to avoid any jolt or jar, since the slightest movement caused much suffering. Two days after her arrival my friend Dr. Buzzard saw her with me, and, after a careful and prolonged electrical examination, came to the conclusion that contractility existed in all the affected muscles, and that the paralysis was purely functional. I could find no evidence in the pelvis of the abscess, the uterus being perfectly mobile, and apparently healthy. After a few days' rest the treatment was commenced on October 16th, the patient being isolated in lodgings with a nurse of my own choosing; and this was the only difficulty I had with her, since she naturally felt acutely the separation from the faithful attendant who had nursed her during her long illness. Her friends agreed not to have communication with her of any sort. It is needless to give the details of the treatment in this and the following cases. A mere abstract will suffice to indicate the rapid and satisfactory progress made.

October 16th.—Twenty-two ounces of milk were taken, in divided doses, in twenty-four hours; on the 17th, fifty ounces of milk; on the 18th, the same quantity of milk repeated; massage for half an hour; on the 19th, milk as before; bread-and-butter and egg; massage for an hour and a half; twenty minims of dialysed iron twice daily; on the 21st, a mutton chop in addition to the above; massage an hour and fifty minutes. To-day she passed water for the first time for four years, and the catheter was never again used. Chloral discontinued, and she slept naturally all night long. On the 23rd porridge and a gill of cream were added to her former diet; massage three hours daily, and electricity for half an hour, and this was continued until the end of the treatment. Maltine was now given twice daily.

30th.—She is now consuming three full meals daily of fish, meat, vegetables, cream, and fruit, besides two quarts of milk and two glasses of burgundy. Considerable muscular power is returning in her limbs, which she can now move freely in bed.

Nov. 6th.—Sat in a chair for an hour. The massage and electricity are being gradually discontinued, and the amount of food lessened.

Nov. 17th.—Walked downstairs, and went out for a drive, and henceforth she went out daily in a bath chair. She has increased enormously in size, and looks an entirely different person from the wasted invalid of a few weeks ago.

On Nov. 26th she went to Brighton quite convalescent, and on Dec. 11th came up of her own accord to see me, drove in a hansom to my house, and returned the same afternoon. She has since remained perfectly strong and well, and has resumed the duties of life and society.

A somewhat curious phenomenon in this case, which I am unable to account for, was the formation on the anterior surface of the legs, extending from below the patellæ half way down the tibiæ, of two large sacs of thin fluid, containing, I should say, each a pint or more, freely fluctuating, and quite painless. I left them alone, and they have spontaneously disappeared.

(To be concluded.)

THE METROPOLITAN DISPENSARY.—The Lord Mayor presided at the biennial dinner held at the Albion Tavern last week in aid of the funds of this institution. Last year relief was afforded to about 8000 persons at the dispensary and about 3000 others at their own homes. Each patient pays a penny at the time of being seen by a medical officer.

A BRIEF OUTLINE OF

DR. ZANDER'S MECHANICO-THERAPEUTICAL INSTITUTION IN STOCKHOLM.[1]

By T. GILBART SMITH, M.A., M.D.,
ASSISTANT-PHYSICIAN TO THE LONDON HOSPITAL.

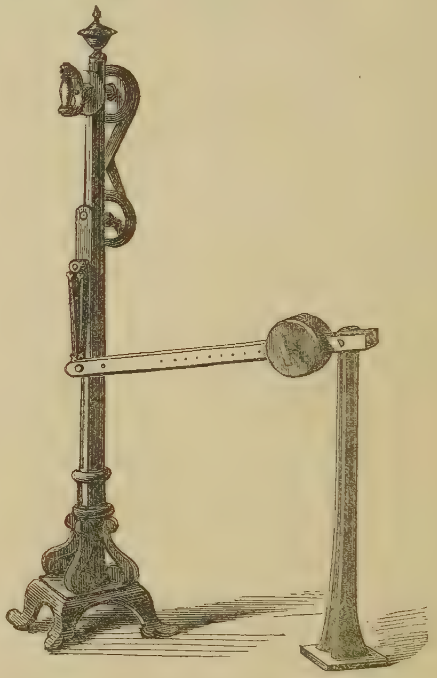
Gymnastic exercise has in Sweden long been regarded as a valuable aid to therapeutics, and what we in England call rubbing and shampooing are there developed into a recognised art. Several institutions exist having for their object the preservation and re-establishment of health by means of muscular exercise and through certain operations on the human body. In these institutes the various exercises are manually performed or induced. The patient is placed in charge of an operator, who stretches, bends, or twists the different joints and muscles of the patient while the latter makes a certain resistance, or the operator himself makes resistance while the patient executes the above-mentioned movements. These are called *active movements. Passive movements* consist of various operations on the body of the patient—such as shaking, chopping, rubbing, &c.,—and are executed by the operator while the patient remains in perfect repose; the object of these movements being to produce wholesome vital activity and a harmonious development by means of judicious exercise. But the achievement of this by manual means is beset with difficulties arising in connexion with both patient and operator. The former may be unable correctly to estimate the amount of force suitable for him to use in the various movements, and may fail to derive benefit by under-estimating what strain he can bear, or may actually diminish his strength by over-estimating the exercise it is capable of enduring without injury; the latter (the rubber) may be deficient in that tact, experience, and judgment which are requisite in order for him to accommodate the increase or decrease of the resistance to the varying strength of the patient upon whom he may be operating. In fact, these manual operations, to be really of use, require that only such persons should be employed as rubbers as are naturally endowed with the requisite qualities (and these are absolutely necessary), and have gained dexterity by long and assiduous training; and, moreover, however well trained the rubber may be, he must at the end of an hour or two be more or less tired, and his sensibility of touch impaired.

Dr. Zander, during his experience as a gymnast, was struck by the difficulty not only of adapting the amount of force to be used by the rubber exactly to the strength of the patient, but also of producing that slow and gradual increase in the use of the muscular power so necessary where employed as a therapeutic agent. To remedy this defect it occurred to him to replace the gymnast by machines, as these could always be regulated to whatever amount of force was desirable, and consequently a gradual increase of their action very easily produced. It is this idea which has been carried out by the Mechanico-Therapeutic Institution.

Dr. Zander was induced to commence experiments twenty-two years ago. After trying several systems of gymnastic exercises, he came to the conclusion that their defects rendered them almost useless, and he therefore set about constructing machines to be worked by most of the different sets of muscles. The resistance made by the machine was adjusted to a maximum and minimum in proportion to the average amount of force generally produced by the respective sets of muscles. The maximum and minimum as well as the intermediate degrees of force were indicated by a graduated scale. Dr. Zander first tried his experiments on the pupils in a large school with which he was connected. He found as a result a marked increase of strength, even in the most delicate children, combined with marked improvement in weight, appetite, and spirits. This led to the opening of his institution in 1865, furnished with twenty-seven machines, which have since then been considerably improved and largely added to. The apparatus of the Mechanico-Therapeutic Institution of Stockholm consist at present of sixty-seven machines: seventeen for active arm movements, eighteen for active leg movements, nine for active trunk movements, and twenty-three for passive movements. In these machines spiral springs are not used for the required force, inasmuch as with a spring resistance is greatest at the close of the movement.

In accordance with nature, in which the muscles act upon the bones as upon levers, Dr. Zander has constructed his machines on similar principles, and the weight to be moved, being placed upon a graduated lever, furnishes a resistance which, conforming to the mechanism of nature, is greatest in the middle of the movement and least towards the beginning and end. By the mechanical method alone can an accurate record of the development of the different muscles and the strength of the remedy suitable to each case be obtained; it provides the patient with a fixed measure of the increase of power gained by him by which he can regulate his exertion.

Arm-turning Machine.



With this apparatus two separate motions are performed—one (*backward*), pronation; the other (*forward*), supination—which act especially upon the muscles of the inner side of the forearm, and in a minor degree on those of the shoulder. The adjustment of the weight upon the lever regulates the resistance in conformity with the strength of the patient. If the arm cannot be held perfectly straight the exercise is too powerful, and the resistance must be diminished.

As an instance of the practical working of this we may suppose the case of a patient who desires to exercise his arm by bending. The apparatus designed for this movement is first arranged so as to offer a weak resistance; should this resistance be too weak it is increased until the patient must make a slight effort to overcome it. The measure of this amount is found on the scale of the apparatus, and the number noted. If the patient finds after some time that what at first was felt to be a slight exertion has entirely ceased to be so, one may conclude that the strength of the muscles has increased, and therefore the resistance of the apparatus must also be increased. The gradual development of the muscular system cannot be obtained in a more perfect manner. It is of much importance to be able thus to modify the amount of exercise with accuracy, especially in cases of weak persons whose sense of fatigue varies from day to day. Movements performed thus by machinery, which never tires or suffers from illness, as is unfortunately the case with shampooers, allow the institution to accommodate a larger number of patients, and that, too, at a moderate cost, an important feature which places the benefits of this mode of treatment within the reach of many. Dr. Zander's institution is open daily from October 1st to June 1st; four and a half hours daily for gentlemen, and two to three hours for ladies. To each patient is given a prescription ordering specified movements, and fixing the force to be employed in accordance with his or her strength and requirements.

---

[1] A paper read before the Medical Society of London, where three of the machines and photographs of others were exhibited to the Fellows.

Although most attend for the relief of some special ailment, yet many go through the various exercises in order to ward off the effects of a sedentary life. Dr. Zander enumerates the following as the complaints which are most frequently treated by him :—Chronic heart and lung diseases, catarrhal condition of the throat, stomach, and intestines, constipation, hæmorrhoids, uterine diseases, paralysis of various forms, cramp, diseases of the joints, such as anchylosis, sprains, &c., rheumatism, spinal curvatures, deformities, &c.

At first sight this method of treatment would hardly appear adaptive to the distressing symptoms of persons suffering from heart disease, but on closer inspection it will be easily conceivable that well-arranged, varied, and regular exercise, if not overdone, may beneficially influence even a circulation disabled by valvular lesion. Judicious muscular contraction by promoting the onward flow of the blood in the peripheral vessels, and by stimulating arterial tension, facilitates the circulation, thus relieving an overloaded and obstructed ventricle and regulating the heart's action. And such practically Dr. Zander has proved to be the case in the large number of patients who attend his institution for the treatment of various cardiac derangements. Their symptoms are essentially mitigated under the judicious use of these mechanical contrivances; palpitations become less frequent, dyspnœa and distress are considerably diminished. In that condition of soft and wasted muscular tissue, combined with general want of mental and physical tone, so invariably found in connexion with convalescence from acute and severe illness, not only does this method provide an invaluable aid to therapeutics, which may induce a speedy restoration to health, but is also well calculated to prevent disorders which so often imperil complete recovery at such periods.

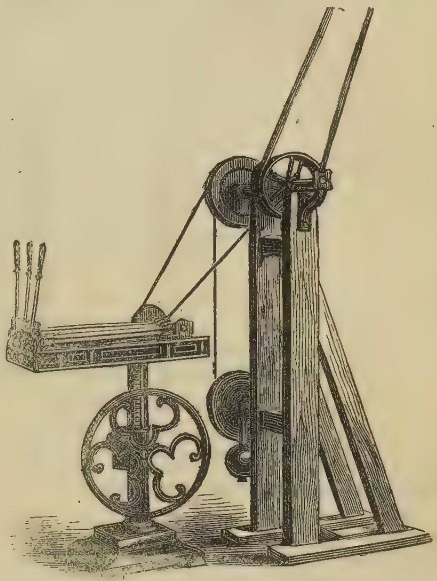
For the treatment of lung disorder, accompanied with deranged bronchial secretion, loss of elasticity, congested vessels with want of power in the respiratory muscles, the mechanical method promises well. Moreover, even during pregnancy, a regular and careful exercise of the muscles has proved highly beneficial to the general health. It is impossible in the scope of this short paper to allude to all the different machines devised by Dr. Zander, or to name even the diverse movements for which they are used; but amongst others I may be permitted to quote their inventor relative to the value of the following passive movements—viz., vibrating, chopping, foot-rubbing, trunk rolling, and chest expansion :

"*Vibrating machine* for shaking various parts of the body. Shakings are especially valuable as curative agents on account of their well-defined physiological effects. On tired or aching muscles and nerves they have a very refreshing and relieving effect. Pain is often entirely subdued by a single shaking during some minutes. Sensitive persons taking a foot-shaking feel a certain sense of coldness in the feet during the operation, but become soon afterwards warmer than before the movement. When taking a shaking on the os sacrum, one can easily feel that the walls of the rectum and the bladder vigorously contract, especially if they are full. Shaking of the chest or the throat facilitates the expectoration in catarrhs, and the absorption of pleural exudations. Shaking of the back between the shoulder-blades has a specific effect upon the action of the heart; it always makes its contractions less frequent and more effective. Persons suffering from nervous palpitation feel very much relieved after such a movement; the pulse has in one case been observed to fall from 130 to 90. In cases of fatty degeneration of the heart, when its action is very weak and very rapid, the back-shakings, together with such movements as facilitate the action of the heart by lessening the pressure of the blood in the arteries, are invaluable.

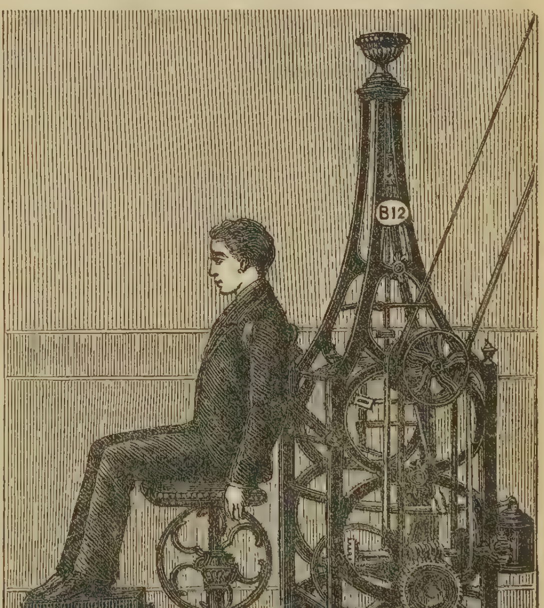
"'*Chopping*' *or rapid* '*hammering*' on various parts of the body has a more superficial effect than shaking. The movement consists of a number of alternating and rapidly succeeding compressions and relaxations of the superficial soft parts, draws the blood to the part acted upon, and produces an increased warmth and vitality. It is used as a stimulant and derivative agent.

"*Foot-rubbing.*—The patient puts the soles of the feet against the rapidly revolving, furrowed wheel, a piece of soft chamois being placed between the feet and the rubbing surface of the wheel. The operation has a stimulating and warming effect, and is very efficacious in drawing blood to the lower extremities.

"*Trunk-rolling.*—The patient takes his seat on a sort of saddle fastened to the top of a vertical lever, the lower end of which is made to rotate in larger or smaller circles, the fulcrum being near to the saddle. By this means the saddle is successively inclined in all directions; the angle of inclination being large in proportion to the diameter of the circle, which the lower end of the lever describes. The patient, seated on the saddle, is obliged to use all the muscles round the waist to keep his balance. Moreover, the abdominal viscera are, as it were, kneaded and rubbed against each other and the abdominal walls; which cannot be without a beneficial influence upon the circulation in their bloodvessels, as well as their respective functions. The movement is used not only to strengthen the back and abdominal muscles, but also to cure torpidity and circulatory disorders of the abdominal viscera.



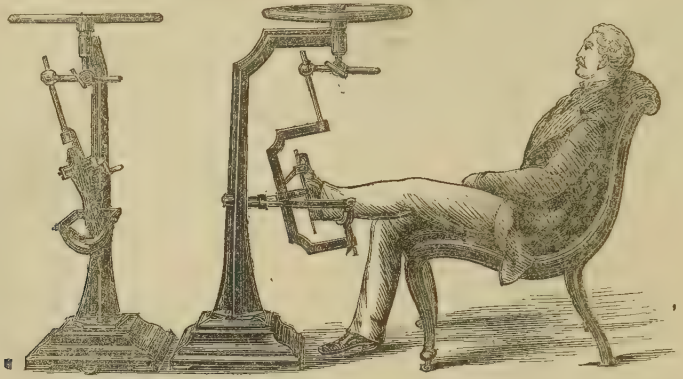
MACHINE FOR RAPID HAMMERING OR CHOPPING.



MACHINE FOR CHEST EXPANSION.

"*Expansion of the chest.*—The thorax is pulled upwards by means of two levers, while a pad makes a horizontal pressure on the back. The trunk is hereby elongated a few inches, and the spine and the walls of the chest are stretched. After some seconds the machine permits the thorax to sink down, and the movement is repeated seven to ten times. The patient remains perfectly passive, only inspiring during the pulling up, and expiring during the sinking of the thorax. Persons who carry on a sedentary life respire very superficially; the walls of the thorax become too stiff, and make the respiratory function laborious; the lower lobes of the lungs partake very little in the respiration. By using the chest expansion, the walls of the chest recover their elasticity, and the patient is made to inspire deeply, so that the air can penetrate to every part of the lungs."

MACHINE FOR ROLLING THE FOOT.



Rolling of the foot acts upon the muscles, which bend and straighten the foot, working the ankle in a circular manner. If the thigh be not fixed, the rolling movements are the result of the action of the muscles of the whole leg. This, while being less tiresome, is not of such benefit to the ankle as when the thigh is kept in a fixed position. It greatly assists the circulation in the lower extremities.

Harley-street, W.

ON GENERAL PARALYSIS OF THE INSANE CONSECUTIVE TO LOCOMOTOR ATAXY.

BY W. JULIUS MICKLE, M.D., M.R.C.P.,
MEDICAL SUPERINTENDENT, GROVE HALL ASYLUM, LONDON.

(Concluded from page 820.)

I WILL now describe an example of general paralysis of the insane following locomotor ataxy, and recently under my care.

CASE. *Locomotor ataxy of about five years' duration; general paralysis of nearly four years' duration; death; necropsy.*—Mr. ——, aged forty-three, married, admitted on July 24th, 1877. As one of his friends expressed it, "he had lived his life." When a youth he had indulged in sexual excess; subsequently he married early, had a large family, and was confessedly amorous in his marital relations. Without drinking to any decided excess, he had always been of a convivial turn, and fond of spending the night with companions, playing at cards, and drinking and smoking more or less. He had been active in his vocation, had worked hard, had been anxious to succeed in business, and ambitious to place his family in still better standing. Physically he was not strong, and had often over-exerted himself. For a long time before the patient's admission his medical attendant (since deceased) noticed the patient's gait become impaired in a way similar to that existing on admission. He had also been laid up with severe pains in the back and limbs after a fall, and for a long period before mental symptoms supervened he had from time to time suffered from sudden, shooting, darting pains in the lower limbs, which usually were only transitory, and even momentary. He had, however, behaved very strangely to his wife on one occasion immediately after her confinement, and about a year before his admission to the asylum. At the time of his admission she was again several months advanced in pregnancy. Pronounced symptoms of insanity, recognised as such, had existed for three weeks before his admission; but for several months the patient had shown some mental alteration, although he was not then looked upon as being insane. Latterly he became speculative, bought and sold horses and cattle, drank more than usual, lent or gave away money to undesirable and unsteady acquaintances, and was unwontedly active, fussy, restless, and violent in temper. During the three weeks of more active symptoms immediately preceding his entry he had threatened to poison his brother, under the delusion that the latter was an illegitimate pretender; he had been coarse and violent in language and in manner before his wife and children, and in public places and railway carriages; his buying and selling had been reckless; his temper violent; his driving furious; his language had been incoherent, and had revealed extravagant views as to his money and possessions. Transactions resulting in loss he declared to be fruitful of gain. He stated that he would live long, and would leave each of his children £10,000; that he was about to buy an estate, and had a horse about to win £10,000 in a race.

On admission, the patient was found to be 5ft. 8in. in height, and to weigh 137 lb.; thin; viscera healthy; cardiac sounds loud, the second widely heard; pulse 120, full, compressible; pupils equal, rather small, slightly irregular in shape, sluggish; tongue protruded slightly to left, irregularly and shakily, pale, large, flabby, indented, furred; face somewhat flabby; occasional facial and labial trembling or twitch during speech, sometimes on the left side only; complexion rather muddy, dilated venules on cheeks; speech tremulous, occasionally slightly hesitating or pausing, and mainly so when he commences to speak. Gait ataxic, steps high and somewhat wide, feet thrown outwards, toes at first out, but turn in at moment of reaching ground, heels somewhat brought down, whole movement of walking irregular, shaky, and jerking. He can stand with the feet close together so long as the eyes are open, but when these are closed he at once sways and falls; with feet wide apart and eyes closed, his frame sways and rocks unsteadily to and fro, but he does not fall. Grasping power of hands good, handwriting shaky, and slightly irregular and erratic. The patient denies having had venereal disease, except gonorrhœa once when young. He speaks of former lumbar pain and tenderness, of former severe pains in legs and feet, and failure of power in the legs. Shortly after admission he twice hurled a flower-pot through the window-glass. Demands £210,000 as compensation for his illegal detention. "Has 400 acres of land, six hunters, three nice grooms, a pack of hounds, and will hunt for sixty years." "Sold seven horses last week for £200 each." "Will win £100,000 each on the Newmarket, Cesarewitch, and Liverpool races." "Has bought 100,000 hats." "Has been kind and good to everyone, and is beloved by all." "His father was the best man who ever lived." Wants to be off; even at midnight demands a cab. Says his wife is here or near at hand; is easily diverted; at one moment crying, denouncing his detention, and threatening vengeance; at another he is smiling, patronising, and good-humoured. Ordered physostigma and iron, and a night draught of chloral and potassium bromide.

After being active, restless, and energetic for a time, he became depressed early in August, weeping often, and the physostigma was omitted, and, as he now slept well, the hypnotic was also discontinued. The face, lips, tongue, and gait were less affected than before. Cod-liver oil was given.

At the end of August the exaltation and extravagant delusions were buoyant. "God had told him that his father and mother were sitting next to Him in heaven, and that after death he himself would sit next to God." "At night he sees angels sitting on his bed." "Has £30,000 a year, and will derive enormous wealth from two patents; will buy and clip all the sheep in the world." Speech, tongue, lips, face, and pupils worse again, and now much as on admission. Iris thrust forward, gait variably ataxic. Pulse 102 and 114, compressible. Resume physostigma and iron.

October.—Very depressed; weeps about being detained; worries about imaginary losses of large sums of money. "Had £1018 from an 'accident company,' which must pay him £300,000 more." Pulse 110.

November.—Occasionally depressed, and even refusing food for a meal or two. Writes letters containing the foulest abuse of some of his friends. Writes letters to me, and to himself, purporting to be from his friends, and to make arrangements for his discharge, and tries to get them secretly posted. Delusions of identity, fancying he formerly knew certain of his fellow-patients. Gait highly ataxic, although he boasts that he can run better than ever. Speech and facial condition, which had been worse, were now improved. Pupils small and somewhat sluggish. Refuses any medicine.

December.—Now takes cod-liver oil.

Jan. 1st, 1878.—"He, his wife, and children will live until the resurrection day. Is God by Jesus Christ. God sent an angel to him last night to tell him so; it perched on his foot, and stroked his face with its wings to wake him; he did not see it, but heard its message and felt its touch." Still makes claims on an "accident company" for large, varying, and often odd amounts.

March.—Weight 137 lb.

August.—Handwriting same as on admission. Gait ataxic, forehead and brows often affected by twitches of occipito-frontalis and upper part of orbicularis palpebrarum; during speech there were occasional twitches about the upper lip, zygomatici, and levatores labii superioris alæque nasi, and either during speech or at other times twitching of the left cheek. Pupils equal, small, slightly irregular, somewhat sluggish. Speech occasionally pausing, hesitating, with partial repetition of syllables, and quasi-stammering. The tongue was tremulous on protrusion, and then slight twitches played about the lips and face. The lower part of the face was losing the lines of expression; the skin was now clear, and there were traces of a florid complexion. Incontinence of urine occurred by day and night. At every passing train he shouted "drop," and explained that whenever he did so the engineers on the train dropped dead, and that 100,000 of them were piled up dead at the station. He struck them dead, he said, because they were quite naked and drove trains without freight or passengers, thus putting him to an enormous expense to repair 4,800,000 carriages. "There are only a dozen people in London, little cads, whose lives he had saved. He had supplied all England with meat and saved her from dying, and God says he's the best man who ever lived. He bought 150 of the best pictures in the world at 1*s.* a-piece." He talks to God, replying to his own queries, and in this imaginary conversation the replies, he says, are uttered by God.

May 6th, 1879.—Weight, 135 lb.

Sept. 15th, 1880.—No patellar tendon-reflex; no ankle clonus, but some twitches and startings when either foot is forcibly extended upon the leg; moderate twitches and jerks of legs in reaction to tickling of soles of feet; pinches of feet are not much noticed; occasional spontaneous, irregular, twitches and jerks of legs. Gait excessively jerking and ataxic; can scarcely take a step safely; in attempting to walk the feet are thrown outwards and the heels are brought down in a wildly erratic manner. Pupils equal, small, act moderately to light and in accommodation. Tongue flabby; very jerkily, irregularly, and imperfectly protruded, twitching and shaking much. Speech much embarrassed; cannot give his name; to everything replies, "All right"; and often wears a happy, fatuous look. Continual incontinence of urine, and, occasionally, of fæces. At and after this time the locomotor disability was so great that he had to remain in an easy-chair. But while in it he continually straightened and extended the lower limbs. The upper limbs also were kept straight and extended, and the forearms extremely pronated, wrists flexed, and hands abducted, so that the palms were turned outwards, backwards, and even somewhat upwards. The voluntary movements of the arms were attended with twitching and jerking, which also occurred when the parts were at rest. As for the usually straight, extended, and more or less rigid legs, voluntary and involuntary movements of them were attended with twitching and jerking, and slight pinches or scratches, or passive motion of the legs brought these on as well. The right foot was in the position of mild talipes varus; there was now slight ankle clonus; speech was much affected; tongue protruded with great difficulty, and with much jerking and twitching of it, and simultaneous twitches of face and lips, the spasm playing over the features for some times afterwards. Some anæsthesia and analgesia, of lower limbs especially. The patient was smiling and "all right" to the last, although at times scarcely able to utter the words. During the last two months of life he was continuously bedridden, and for a month or two before that had been unable to leave an easy-chair.

Dec. 23rd.—Severe convulsions came on at 2 A.M., but had ceased by the time he could be seen by the medical officer called to him. After the convulsions the patient became, and continued to be, comatose, with slow pulse, infrequent gasping respiration, livid and pale face, and pupils of moderate size. Brandy enemata were given. Died at 10 A.M.

Necropsy.—Brain: Dura mater slightly thickened and congested. Olfactory tracts and bulbs wasted. Optic nerves rather shrunken, but white. Other cranial nerves of ordinary appearance. Arteries at base of brain healthy. Superior and posterior meningeal veins full; meninges hyperæmic. Arachnoid highly opaque over superior external and internal cerebral surfaces; the opacity is patchy, it is only slight over the tips of the occipital lobes. Pia-matral œdema, corresponding in relative degree and distribution with the opacity of arachnoid. Adhesion and decortication of summits of gyri marked. On the right cerebral hemisphere this adhesion occurs especially over the entire upper surface of the first and second frontal gyri, and over that part of the third adjoining the vertical branch of the Sylvian fissure. Scattered points of the same are found on both ascending convolutions; the supra-marginal gyrus suffers severely, the angular rather less, the postero-parietal lobule slightly, the first occipital very slightly, the temporo-sphenoidal are considerably affected along their whole external surface, the under surface of the temporo-sphenoidal lobe suffers somewhat, the back part of the orbital surface considerably, as also the inner cerebral surface bordering on the periphery of the great cleft. On the left hemisphere are well-marked, extensive adhesions over nearly the whole area of the summits of the first, second, and third frontal gyri, the lower two-thirds of the ascending frontal, and the supra-marginal. Moderate adhesions over angular, front part of postero-parietal, whole external and inferior surfaces of temporo-sphenoidal lobe; also on orbital surface. Slight adhesions over front part of occipital lobe. The ascending parietal escaped this change, except its lower half inch. Surface of erosions reddish. Grey cortex wasted in frontal and parietal regions; rather pale at base. Brain considerably vascular; also soft and flabby, except the anterior portions of white substance. Fornix diffluent. Lateral ventricles appear fairly healthy. Basal ganglia rather soft, and contain a liberal blood-supply. Cerebellum: Some adhesions on its surface, consistence rather diminished. Pons Varolii and medulla oblongata rather soft and vascular. Ependyma of fourth ventricle thick, and of a gelatinous sanded appearance. Weights: Right cerebral hemisphere, 18½ oz.; left, 17¾ oz.; cerebellum, 5¼ oz. Pons Varolii and medulla oblongata, 1 oz. Fluid from brain, &c., 3 fl. oz.—Spinal cord: Meninges thickened, chronically inflamed. Spinal dura mater congested. Spinal pia mater thickened, particularly over the posterior aspect. Well-defined grey degeneration and induration of the posterior columns of the cord. This is most marked in the lower dorsal region, where the grey degeneration affects the entire width of the posterior columns, ceasing on each side with the posterior horn of grey matter and posterior root-zone; at least, extension to the lateral columns was not obvious in the sections examined. At this portion of the cord the posterior nerve-roots are grey and indurated. But as the grey degeneration is followed upwards, instead of reaching transversely from posterior nerve-root to posterior nerve-root, it gradually becomes limited to that portion of the transverse section which extends half-way from the posterior median fissure to the posterior grey cornua, and finally, at the upper part of the cervical region, is almost confined to the slender posterior median columns. This limitation gives it something of the aspect of a secondary lesion here. The posterior roots of the cervical spinal nerves are of natural appearance and consistence. Above, the sclerotic change runs to the rib of the calamus scriptorius, where it ceases on the surface, and apparently ends, or dips into the floor of the fourth ventricle.

THE PATHOLOGY OF HEPATIC CIRRHOSIS.[1]

By WM. ROBERT SMITH, M.D., F.R.S. Ed., F.C.S.,
PHYSICIAN TO THE CHELTENHAM DISPENSARY.

Before entering upon the subject matter proper of hepatic cirrhosis let me refer very briefly to the normal structure of the liver. It is a very large glandular organ situated in the right hypochondrium, weighing on an average about three pounds. It measures in its transverse diameter from ten to twelve inches, and from six to seven in its antero-posterior, and at the back part of the right lobe, which is always the thickest part, two and a half to three inches. Its upper surface is convex, and, owing to its capsule, is smooth, regular, and glistening, of a bluish-pink colour, whilst its under surface is concave and mapped out into several lobes by the various fissures. On section the liver is found to be of a chocolate colour, of a firm elastic consistence, and to be composed of lobules, which are, however, very indistinctly seen. The various openings are in great part those of the portal veins, the others being hepatic veins. Under the microscope the capsule is found to be attached to the liver by bands of connective tissue, which join the connective tissue of the stroma of the organ. The lobules are remarkable for the great indistinctness of their outline. This is their normal appearance. At the centre of each lobule is the opening of the hepatic vein. This varies very much in size. From it radiate the rows of liver cells which form the bulk of the substance of a lobule. The cells are nucleated protoplasts having no periplast, and more or less spheroidal in form, but their shape varies much, owing to pressure from their fellows. They are from the one-thousandth to the two thousandth of an inch in diameter. Round each cell is a small capillary bile-duct.

The hepatic artery ramifies in the middle part of the lobule, breaking up into a capillary network, which encloses the cells. The portal vein is distributed at the lobular periphery. For pathological purposes, then, the liver is divided into lobules, and the lobules into three zones: the inner, or zone of the hepatic vein; the middle, or zone of the hepatic artery, and the outer, or zone of the portal vein.

In cirrhosis of the liver the morbid appearances found in cirrhosis are of two kinds: in the one case the liver is reduced in size, when it is called the coarse cirrhotic—the small, hobnail, or gin-drinkers'; whilst in the second variety the liver is enlarged, when it is called the fine cirrhotic, the hypertrophic or large.

We will take the small variety first, the coarse cirrhotic. In this the liver is much reduced in size, being about one-third its normal state; it has also lost weight; very tough in consistence, resembling a piece of soaked leather more than anything else; it is hard and has a distinct fibrous feeling. The surface of the organ is very irregular, being marked with elevations varying more or less in size from the dimensions of half a millet seed to those of a small filbert. These elevations are rounded masses of fibrous tissue enclosing perhaps in some instances small portions of the liver parenchyma, and between these elevations are depressions where the capsule is found to be very much thickened; the edges of the organ are thinned, and finally become a mere indurated border containing no liver tissue.

On section very often great resistance is experienced, resembling that met with in dividing a scirrhous growth, and the same elevations are seen as on the surface. The organ is usually found jaundiced of a canary or olive green colour, whilst the whole of the cut surface appears to be beset with fibrous tissue; the large branches of the portal vein are usually much dilated and filled with blood.

Under the microscope the capsule is seen to be very irregular in outline, showing elevations and depressions. Below this the subcapsular tissue is much thickened; in some cases it is alone thickened, whilst certainly in the majority it is more thickened than the capsule. From the capsular depression bands of fibrous tissue proceed, which, as we trace them into the liver substance, are seen to divide dichotomously, enclosing within these divisions several lobules of the liver. These bands shortly contract very much, causing the depressions in the capsule, and sooner or later the destruction of certain of the cells by fatty degeneration.

The fibrous tissue is composed of three elements: first, of small, round, embryonic cells; second, of a large quantity of white fibrous tissue, yellow elastic tissue never being reproduced in the body; and, thirdly, of very delicate, spindle-shaped cells. If the fibrous tissue is young, the small, round, and spindle-shaped cells will be found in greatest abundance, whilst if the tissue be older the white fibrous tissue preponderates. No doubt part of this tissue arises from the connective tissue investing the individual lobules, but by far the greater part comes from the liver cells. In the first place, the nuclei of these cells are seen to enlarge considerably; this enlargement is rapidly followed by their division; very shortly then division of the whole cell takes place. This cycle of changes goes on over and over again, the nuclei being large, whilst the protoplast is small, until at last free nuclei are produced. These then elongate into spindle-shaped cells, and ultimately develop, into the white fibrous tissue. The remaining cells undergo atrophy from fatty degeneration, and so the whole of the cellular elements are destroyed.

The fibrous tissue is abundantly supplied with blood-vessels. In the section under the microscope the vessels will be seen both large and numerous. The smaller branches of the portal vein are in great part compressed or obliterated by the cicatricial tissue, whilst the area of distribution of the hepatic artery steadily increases. To this narrowing of the portal veins may be traced the dilatation of the larger branches and the subsequent congestion in the intestines and spleen, the ascites and other distressing symptoms. Owing to the increase in the distribution of the hepatic artery and the diminution in the size of the lobular portal capillaries, the bile is, to a great extent, elaborated from arterial blood.

The hepatic ducts, as a rule, remain pervious, the jaundice, which so frequently occurs in cirrhosis of the liver, especially towards the fatal termination of the disease, is most probably owing to a catarrh either of the hepatic duct or the ductus choledochus, or both, causing swelling of the mucous membrane, and consequent obstruction to the exit of the bile.

In the second variety of cirrhosis, the fine, hypertrophic, or large, the organ is found to be enlarged in size, whilst the surface is uniformly smooth, or but very finely granular. On section the organ is seen to be jaundiced, and much portal distension is present. The fibrous tissue, however, is more distributed, and each lobule is distinctly mapped out by a band of cicatricial tissue, enclosing and isolating it. This tissue does not undergo contraction to the extent so remarkably characteristic of the coarse variety, and consequently we do not find the irregularities of the surface, the elevations and depressions, which were such marked features in the other variety, nor do we notice in this form of the disease that extensive destruction of the cellular elements which was so noticeable in the other. The reason the organ is increased in size is that the tissue is so abundant it more than compensates for the loss occasioned by the destruction of the cells.

Royal Hospital for Children and Women.—The claims of this institution were, on Wednesday last, warmly advocated by the Prince of Wales, who presided at a dinner given at Willis's Rooms in aid of the funds of the hospital. The annual expenditure in working the charity is, it appears, nearly £2500 more than the present subscribed income; and there is at the present time a sum of £3000 required to meet the expense attending the purchase of freehold deemed necessary to complete the building Over £2000 in contributions were announced at the meeting.

The salary of Dr. Robinson, medical officer of the old workhouse, Lambeth, has been increased from £50 to £75 per annum.

PYÆMIA AFTER ENTERIC FEVER.

BY R. BRUCE LOW, M.D. EDIN.

THE occurrence of pyæmia in the course of enteric fever is of sufficient rarity to warrant me in placing the details of my case on record. I shall briefly relate the facts.

J. A——, aged fifty, a farmer, was attacked with enteric fever, and passed through the usual phases of this disease till the twenty-first day, when he had an alarming collapse. He was pulseless at the wrist, and the skin was bathed with a cold and clammy sweat, which was believed to be his "death agony." From these and other symptoms perforation was diagnosed, and an unfavourable prognosis was given. Restoratives, with other remedies, were prescribed, and he rallied. Two hours after the collapse his pulse was 140, and his temperature 97·2°. For the next seven days he remained free from pain, but with a slightly tympanitic abdomen; his stools were black at first, but gradually became pale and semi-solid, being studded with "scabs" on certain occasions, as stated by his wife. The temperature between the twenty-first and twenty-eighth days remained about normal; on the last-named day it was 99·8°. On the twenty-ninth day, or eight days after the collapse, he was seized with a most violent and prolonged rigor, followed by a very profuse perspiration, which saturated his night-shirt, and extended to the ticking of the bed on which he lay. The next day he had three severe rigors, followed by some copious sweats; and from this date, the twenty-ninth day of his primary illness, till the sixty-second (or thirty-three days from his first rigor) he continued to have rigors and sweats at more or less regular intervals. The morning, about nine o'clock, was the usual time of the attack. After the rigors had continued a week they began to miss a day, and, finally, they missed two days; but on all occasions the shiverings were of the most prolonged and most severe character, and were always followed by such sweatings as actually to cause the bed-ticking on which he lay to rot. The temperature, pulse, and respiration were taken regularly from the beginning of his illness for a period of sixty-five days, two or more observations being noted each day. After the first rigor the temperature rose to 103·4°, the pulse to 124. The highest point reached after a rigor was 105°, the highest point of pulse and respiration being respectively 160 and 52. It was noted that each rigor was followed, sooner or later, by the expectoration of a few mouthfuls of bloody sputum, which contained nearly always a small clot or coagulum about the size of a pea. This bloody sputum occurred only after a rigor, and at no other time during the illness; this fact is interesting as bearing on the diagnosis, as will be seen. The patient had severe diarrhœa after the twenty-eighth day, most offensive and at times containing blood. He had often vomiting before or after the rigors. No physical signs of consolidated lung could be made out. The right foot and leg became painful, and ultimately a large and painful swelling occurred in and around the ankle joint. He became now greatly prostrated, and could not even turn himself, and his motions were passed in bed. He often had a tendency to faint when the bowels were being moved. When the rigors missed a day the temperature remained normal, the pulse and respiration also came down. His skin became yellow and shrunken. He lay with his eyes shut and asked to be allowed to die without being disturbed. From this point he began to mend, and his last rigor is noted on the sixtieth day of his illness. For three months after this the patient was unable to go out of doors, but now he is able to go about on his farm. He is, however, still in feeble health.

Although writers on the subject of pyæmia admit that it may occur as a sequel of typhus, variola, or enteric fever, yet doubt is often thrown on the records of these cases. It is asserted that the diagnosis of enteric fever has not in these cases been satisfactorily made out, or if it has, that the so-called pyæmia has been only a relapse of the fever, an acute pneumonia or the like. That the case I have just related was in the first instance purely enteric is proved by the clinical history of the case, the presence of the usual symptoms, the spots, the diarrhœa, the temperature, &c. Two medical men saw the case with me, and concurred in the diagnosis. Enteric fever had seized twelve persons already in the neighbourhood. Seven of these cases were in the same street. During this illness the patient's eldest daughter, aged twenty-one, who had helped to nurse her father, took enteric fever, and died from hæmorrhage from the bowels on the sixteenth day of her attack.

In discussing the diagnosis of pyæmia I may state that the patient had a small bedsore on his sacrum before the collapse came on. As to pyæmia being the secondary affection, I point out the occurrence of the prolonged and recurrent rigors, followed by the profuse perspirations and the apparently normal condition between the rigors; the local lesions in the lungs, as shown by the expectoration of the extravasations, or pulmonary clots, which had ruptured the capillary network and thus escaped, and also by the inflammation and threatened suppuration of the ankle joint. The absence of other local morbid manifestations may be accounted for by the fact that in a certain class of cases of pyæmia the lungs are the only organs which are affected by these extravasations, and it is well known that the lungs are almost invariably affected by these deposits in pyæmia. Again, our patient had the intense prostration, the sickness, the bloody stools, the sallow countenance, and so on. The temperature showed a characteristic change from the typical enteric form. After the rigors it always rose, and it invariably on this account had its highest point in the forenoon and its lowest in the evening. The high pulse (160) after a rigor, and the quickened respiration (52), returning to almost normal in the absence of the rigors, are also points worthy of remark. What was the immediate cause of the pyæmic infection I cannot pretend to say, but it seems to have proceeded either from the lesion of the intestines, perforation, or abscess from local peritonitis in the region of an ulcerated Peyer's patch, or it may have resulted from purulent infection from the small bedsore on the sacrum. There is no ague in the district; the patient had never been abroad.

The house in which the patient lived was extremely defective in its construction. The old thatched roof was rotten and admitted rain in many places, the walls were blackened with damp, and the only ventilation in the sick-room was by means of the room-door. There was no fireplace in this damp bedchamber. The usual sanitary defects of these rural homesteads were present in an exaggerated form. I may say that no puerperal septicæmia or surgical fever had been found in the district for many years, and that therefore there could have been no infection from without. The treatment adopted was the ordinary rational treatment of such cases, known to all medical men who are interested in the subject. I need not, therefore, recapitulate; but only mention that quinine, stimulants, and the rigid enforcement of all possible hygienic measures, with an almost unvaried diet of milk, soda-water, and brandy (of which combination he never tired), were the remedies chiefly relied upon.

Helmsley, Yorks.

CASE OF PAPILLOMA OF FAUCES; REMOVAL.

BY J. LLOYD, M.B., M.S. DURH., F.R.C.S. ENG.

W. J——, aged seventeen years, a strong robust youth, consulted me about six months ago, suffering from sore-throat, evidently the result of catarrh. He soon shook off this condition under simple treatment, but it was followed in three or four days by an attack of monarticular rheumatism, the joint disease being confined entirely to the left knee, and accompanied by high temperature, loaded urine, and sour-smelling sweatings. I have related these few facts as illustrating a point to which attention has recently been called, the association of sore-throat with acute rheumatism. When examining his throat I noticed a growth attached to the right anterior pillar of the fauces; it was the size of a horse-bean, cauliflower-like in its surface, pale in colour, covered by a mucous membrane similar to that lining the general buccal cavity; it was pedunculated, soft and freely movable, lay between the root of the tongue and the fauces, and was painless and not very sensitive to pressure. He says he first noticed it about eighteen months ago, that it gives him neither pain nor inconvenience; he thinks it grows a little larger, but decidedly objects to have anything done for it, as he has been told that if it is cut he may bleed to death.

I had occasion to see this patient again early in March for a small superficial abscess of the cheek, and at the same time

I examined his faucial tumour. It was decidedly larger than when I saw it between five and six months previously. It was now the size of a marble, otherwise it had not altered in appearance. At the patient's request I removed it by simply catching it with vulsellum forceps and cutting off with curved scissors, being careful to take away the entire thickness of mucous membrane at the base of the pedicle. There was scarcely any hæmorrhage and little pain, the whole thing being too simple to deserve the name of "operation." There is now no sign of recurrence (two months afterwards), and no mark to indicate from where the tumour was removed. To the naked eye, after removal, the little growth had the characteristic appearances of papilloma; it was soft, compressible and branched, and very much resembling an ordinary gonorrhœal wart. It was composed of connective tissue covered by elongated papillæ with their surrounding thick layer of squamous epithelium.

I have considered this case, although not a serious one at the time of its treatment, well worthy of record from its comparative rarity and from the unmistakable features possessed by the growth. Although not strictly speaking a tumour of the pharynx, yet from its position it may have given rise to some of the accidents incidental to those tumours, such as impaction in the larynx, &c., and may also have been expected to resemble them in structure. I have been unable to find any case recorded as papilloma, undoubtedly the variety of tumour under which the present one would be classified by modern pathologists. The "soft fibrous tumour," described by Billroth as occurring almost exclusively in the cutis, approaches in appearance and structure the nearest to my case; this kind of tumour consists, however, of a maximum amount of connective tissue with a minimum of papillary growth, whereas in my specimen there is a maximum of papillary hypertrophy with very little connective tissue development. Another point I should like to mention is that in excision of any papillomatous growth less hæmorrhage follows its removal when the whole thickness of skin or mucous membrane is taken away than when the incision is carried more superficially. This fact was well illustrated in a case of gonorrhœal papillomata, which I recently removed from a young woman, where the growths extended from the pubes to the coccyx, completely obscuring the pelvic outlets and being as large as two closed adult fists. The tumours were rapidly excised with scissors, the whole thickness of the skin at their bases being taken away; the hæmorrhage was easily controlled, and the patient made a quick and perfect recovery. This treatment also does away with the necessity of applying caustics to the bases from which the tumours are cut away.

MIDDLESEX HOSPITAL.

INTRA-UTERINE FIBROID TUMOUR, SESSILE; ITS ENTIRE DISCHARGE BY EXFOLIATION PROMOTED BY INCISIONS OF GRADUATED DEPTH INTO THE GROWTH.

(Under the care of Dr. HALL DAVIS.)

FOR the following notes we are indebted to Mr. W. E. Dixon, obstetric physician's assistant.

Elizabeth J——, aged twenty-eight, single, of dark complexion, and medium stature, was admitted on May 9th, 1879, on account of uterine hæmorrhage, of which she had been the subject for the last five months, most copiously at the menstrual periods.

On admission, the muscles were flabby, the lips, gums, and tongue pallid. Pulse 80; temperature 99°. An enlargement of regular outline in the central position could be distinctly felt on abdominal palpation, extending upwards from the pelvis to within an inch of the umbilicus. Vaginal examination discovered an enlargement of the body of the uterus, with an elongation of its neck. The axis of the uterus was very nearly in the axis of the pelvic brim. The uterus was mobile; its orifice would not admit the passage of the forefinger. The patient complained of aching and shooting pains in the hypogastric and sacral regions, reaching down to the knees. The patient was debilitated, constipated, the subject of palpitation of the heart, and of cardiac and arterial murmurs due to anæmia.

The bowels were first fully relieved by enemata and mild aperients. The os uteri was then gradully dilated by laminaria and sponge tents. The os uteri was thus at length sufficiently dilated to admit of the passage through it into the cavity of the uterus of the index-finger, and around the free surface of the tumour. This was felt bulging inwards from the anterior wall of the uterus, to which it was found attached sessile. Dr. Davis attempted to detach it from the uterus with the fingers, but its intimate union made that endeavour unsuccessful. The depth of the cavity, taken by the uterine sound, measured four inches. The patient was now placed under anæsthesia by ether, and the metrotome introduced into the uterine cavity, the knife being projected to the third of an inch, at the same time applied to the tumour, and drawn down through it; the os was also intentionally incised while withdrawing the metrotome.

No hæmorrhage of any consequence followed, but some pain ensuing was subdued by twenty minims of Battley's sedative solution. The uterus was washed out daily with Condy's fluid. During the following days portions of the tumour were discharged. The pulse generally was 100; the temperature from 99° to 102·6°.

On May 30th a repetition of the previous operation was resorted to under ether, after dilatation of the uterine orifice, as the tumour had not been wholly cast off, and therefore the cause of the hæmorrhages was not removed. More of the growth was discharged; some febrile disturbance followed, with a temperature of 103°, but this soon subsided.

On June 12th a re-examination discovered as yet a portion of the growth remaining, which, being incised, was entirely expelled, leaving the uterus perfectly free from all remains of the tumour, as ascertained by careful examination of the interior of the uterus.

No hæmorrhage had recurred since the first operation.

Note.—Since Aug. 11th the patient had been able to sit up daily, a tonic and restorative treatment having been pursued. On Aug. 25th she was sent to her home near Droitwich for further convalescence. Several months subsequently, having received a proposal of marriage, she returned to the hospital for an opinion as to her then condition and as to the question of matrimony. Dr. Davis found the uterus had quite subsided into the pelvis, and learnt that the hæmorrhage had not recurred even at the menstrual periods. She was informed that she might consider herself cured, and could arrange for her marriage after a further accession of strength.

Another case of sessile intra-uterine fibroid, equally therefore non-removable by the écraseur, had been in the hospital under Dr. Davis, but in which one section only of the growth had been followed by the expulsion after a few days' interval of the entire mass, and thus of the removal of the cause of heavy losses of blood.

INTRA-UTERINE AND INTRA-MURAL FIBROID OR MYOMA, REMOVED BY ENUCLEATION.

(Under the care of Dr. HALL DAVIS)

For the following notes we are indebted to Mr. R. M. Webster, obstetric physician's assistant.

Florence K——, aged thirty-five, married, stout, a blonde, blanched, was admitted on Feb. 21st, 1881. Her father died of phthisis; mother, brothers, and sisters healthy. Her menstrual function commenced at the age of twelve, and recurred at intervals of three weeks, but not profusely nor painfully. She married at nineteen, but did not conceive till seven years afterwards, when she had a premature labour through falling downstairs. A year later she had at full term her only child, now seven and a half years old.

At the end of September, 1880, the catamenia commenced to recur every fortnight, and profusely, lasting from nine to twelve days, attended by blood-clots. She was at first, for five days, an out-patient, but was then advised to come into the hospital. On admission she had all the appearances of anæmia. Pulse 100; temperature 96°; great pallor of surface and of the exposed mucous membrane; breath sounds generally and percussion note normal; a few crepitant râles at bases of lungs behind were alone heard; there was a slight cough; a systolic murmur heard all over the cardiac region and slightly in left axilla; no venous-hum heard above the clavicles. Vaginal examination of the uterus showed it to be bulky and suspended below normal level in the pelvis. The os uteri just admitted the index-finger, and within the uterine cavity was felt a smooth, dense fleshy body. The sound passed in beyond the normal depth, and could be swept around the enclosed tumour. The uterus could not be perceived above the pubes. Urine: sp. gr. 1027, acid, slightly albuminous on submitting it to the action of heat and nitric acid. Bowels constipated; tongue, besides being blanched, slightly furred; some headache.

To correct an offensive uterine discharge a solution of Condy's fluid was injected and an aperient given; guarana was administered at intervals with relief to the headache.

On the 24th and 25th, after washing out the uterus, sponge tents were inserted within the neck of the uterus, between it and the polypus, and changed for fresh ones of larger size at intervals of three or four hours.

When the required dilatation had been effected the single wire loop of an écraseur was adjusted around the polypus, and the wire gradually tightened till it crushed through its substance. On re-examination it was found that only about one-third of the growth had been removed. Therefore the loop was immediately again applied, pushed up over the tumour, the uterus being at the same time depressed, and the wire was tightened close to the uterine surface, but before it had made its way half through the dragging on the mass led to enucleation of the growth at the point of its attachment, which appeared to be situated within the uterine wall, and presented at the site of its connexion a convex surface. The patient was placed under anæsthesia by ether during the second application of the écraseur, as she had become restless. The entire polypus, which proved to be a myoma, was of the size of a full-sized fowl's egg. The uterus was afterwards washed out with a solution of Condy's fluid morning and evening as long as necessary, and the patient made a good recovery under ordinary treatment and a generous diet, completed by bitter and chalybeate tonic, being discharged convalescent on March 11th. About four weeks later she visited the hospital again with scarcely any pallor, and had had a normal period. A few weeks later she again applied, but only to assure us of her complete recovery and thankfulness. The anæmic murmurs had entirely vanished.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

RHEUMATIC FEVER WITH HYPERPYREXIA AND COMA; COOL BATH; CURE.

(Under the care of Dr. CARTER.)

EMMA R——, aged thirty-three, married and the mothe of a large family, was admitted on December 18th, 1880 suffering from her first attack of rheumatic fever. She had had slight pains for about ten days, but had only been confined to bed since the 13th. For the first three days the case presented nothing special beyond the fact that slight noise in the head was complained of before treatment was commenced, and that she had not slept for several nights owing to the intensity of the pain in the larger joints. Beyond this sleeplessness, which was easily accounted for, and the slight tinnitus there was nothing in her appearance, symptoms, or antecedent history leading to the anticipation of cerebral disturbance. She was a well-nourished, healthy-looking woman. Bowels regular; heart's sounds normal; pulse 104; respiration 28; temperature 100·2° at 11 A.M. A milk diet was ordered. The joints were wrapped in cotton-wool, and at 2.30 P.M. she commenced taking a mixture containing in each dose twenty grains of salicylate of soda and twenty minims of bromhydric acid. The first six doses were given at intervals of an hour, and the temperature had fallen from 101·8° at 2.30 P.M., to 99° at midnight. After the sixth dose the medicine was given every third hour. The pains, which had been so severe that all pressure of the bedclothes had to be taken off the inflamed joints, were greatly relieved, but it was noticed that with this relief and the fall of the temperature which accompanied it there was no corresponding decline in the pulse, which at midnight was still 114, and during the next two days varied from 114 to 122, the temperature being generally low, and only once for a short time reaching 101°. After the ninth dose of medicine she complained of deafness and giddiness; the respiration became somewhat sighing, and she vomited slightly at 4.30 P.M. on the 19th. Upon this the medicine was ordered to be given every fourth hour, and in soda-water. She again vomited at 10.15 P.M., but afterwards passed a good night. During the day the face had been flushed, and she had perspired profusely. On the 20th she was quite free from pain, had less noise in the head, but, as she had again vomited twice, and still complained of giddiness and deafness, the medicine was discontinued at 2 P.M. At 5.30 she for the first time became delirious. Immediately after the commencement of the delirium, which was at first mild, the temperature was only 101°, but whether it rose during the next few hours is uncertain, as her violence soon became such as to prevent the possibility of using the thermometer. To the hand, however, the skin felt quite cool. As she obstinately refused to take either food or medicine she was brought under the influence of chloroform, though with much difficulty, in consequence of her violence; and while unconscious two attempts were made to introduce enemata containing chloral hydrate and bromide of potassium into the rectum, but these were not retained a moment. Immediately on coming from under the influence of the chloroform she became as violent as ever; it was once more applied, therefore, and a quarter of a grain of acetate of morphia injected hypodermically. Further attempts, made later on, to introduce nutrient enemata into the rectum were unsuccessful. She slept well, but the temperature began quickly to rise, and by 2.10 A.M. of the 21st was found to be 105°, when the surface of the body was sponged with tepid water. The temperature fell under the sponging, which was twice repeated, to 100·6° at 5.30 A.M. At 6.30 she awoke, when the house-surgeon, finding her still delirious and refusing to take either food or medicine, again injected a quarter of a grain of acetate of morphia. At 7.45 the temperature was 106·2°. By 10.50 it had fallen to 104·4°, but at 11.50 was 107°. The patient was then deeply comatose, and unable to be roused by any external stimulus. It was not quite clear how long this very high temperature had lasted, as an hour had been allowed to elapse between the last two observations, and during that time an increase of nearly three degrees had taken place. She was immediately put into a bath at 90° F., while cold water was steadily poured over her head, and the temperature of the bath reduced by also running in cold water. She was in the bath an hour. In about twenty-five minutes, her body temperature having fallen to 103°, she became conscious, and ten minutes before being taken out made some rational observation and drank a little brandy-and-water—the first drink or nourishment of any kind that had been taken for twenty hours. When removed from the bath her temperature was 99·6°, and fifteen minutes afterwards 98·4°. She then took some warm beef-tea, and during the afternoon plenty of warm milk. The pulse for the first time since her admission fell to below 100. After this there was no difficulty. She slept well on the night of the bath; had slight pneumonia of the right base on the 22nd, which ran a very mild course and disappeared in a few days, to be followed by a moderate return of her rheumatic symptoms. These in turn were easily subdued, apparently by the use of smaller doses of the salicylate, and after a few weeks' residence she was dismissed quite well, no cardiac complications having been developed.

There can be no question that but for the bathing at midday on the 21st this patient would never have rallied from the state of coma, with hyperpyrexia, into which she had then passed.

STOCKTON HOSPITAL.

AMPUTATION BELOW THE KNEE IN WHICH NO LIGATURES WERE REQUIRED; RECOVERY.

(Under the care of Dr. FOSS.)

FOR the notes of the following cases we are indebted to Mr. John Hassall, M.B., house-surgeon.

J. H——, aged ten years, a school-girl, was admitted Sept. 18th, 1880. The girl was crossing the railway, when an engine struck her on the right side of the forehead and knocked her down. She rolled over to save her body, but was unable to get her left leg away in time to prevent the whole train passing over it. She was first removed home, and subsequently taken to the hospital. During this time a considerable amount of blood had been lost.

On admission severe shock was present. The face was pale and the extremities cold. The pulse was feeble. On the inner side of the left limb there was a deep wound commencing about the junction of the middle and lower thirds of the leg which ran along the posterior border of the tibia round the external malleolus and across the ankle to the outer side of the foot. The ankle-joint was opened into; the tarsal bones were comminuted; the vessels were torn across, and the tendons dragged out of their sheaths.

The patient having been placed under chloroform, Dr. Foss amputated through the upper third of the leg. The posterior flap was made by transfixion, and the anterior by cutting from without inwards, and consisted chiefly of skin. The limb having been removed, it was noticed that there was no bleeding from the flaps. The pulse could not be felt either in the femoral or radial artery. The breathing was regular. The surface of the body was cold. In a little time the pulse returned at the wrist, and a few seconds later could be felt in the groin. But still there was no hæmorrhage from the stump, so the flaps were brought together with silver sutures and the patient removed to bed.

She made a steady recovery, somewhat delayed by two granulating patches, which refused to heal until skin grafts were placed on them.

AMPUTATION THROUGH THE LOWER THIRD OF THE THIGH; DEATH FROM SECONDARY HÆMORRHAGE FIVE DAYS AFTERWARDS.

(Under the care of Dr. Foss.)

J. T——, aged forty-six years, was admitted to the hospital on March 24th, 1881, at 3 A.M. The patient's right leg had been caught in some machinery and severely crushed. The tibia and fibula were comminuted from the upper third downwards. The vessels were torn across, and these, together with the skin, were torn and contused. Chloroform having been administered, Dr. Foss amputated the thigh at a little above the condyles. The flaps being formed according to Teale's method, only the femoral artery required a ligature. The flaps were brought together by silver wire sutures. Not much blood was lost during the operation, but apparently before being brought in he had lost some, and at this time was suffering from this and a good amount of shock. The same morning, at nine o'clock, the temperature was 98·2°. In the evening the temperature was the same; the pulse was 116. A sedative draught was prescribed. He slept during the night and next morning. Pulse 120; temperature 100·4°. The dressings were stained with blood. Complained of pain in the stump, also in the other leg.

On the 27th the wound was dressed for the first time. The wound looked well; there was no tension or sloughing of flaps; no hæmorrhage.

About 10 A.M. next day the nurse noticed that he had fainted, and it was discovered that there was bleeding from the stump. Notwithstanding stimulants, he went into a state of collapse, and died in about half an hour. The quantity of blood lost was not large, but considering his condition, it was sufficient to cause death. A hurried examination of the stump was made after death, but no point from which the hæmorrhage could have come was observed. The ligature was firmly fixed in the femoral artery, and there was an organised clot inside it.

The Levee.—The following members of the medical profession were present at the levée held at St. James's Palace on Monday last:—Surgeon R. F. Adams, Surgeon T. Archer, Surgeon J. Battersby, Surgeon E. Butt, Surgeon L. H. Carter, Surgeon G. J. Coates, Surgeon S. A. Crick, Surgeon-Major J. S. Comyn, M.B., Surgeon-Major A. F. Churchill, Surgeon J. G. Crofts, Surgeon G. W. H. Cook, Surgeon A. B. Cottell, Surgeon F. A. B. Daly, Surgeon J. R. Dodd, Dr. Peter Eade (Sheriff of Norwich), Surgeon-Major B. Franklin, Surgeon-General S. H. Fasson, Surgeon R. W. Ford, Surgeon W. Deane-Freeman, Surgeon S. G. Hamilton, Surgeon-Major H. F. Hensman, Surgeon-Major E. Hoile, Deputy Surgeon-General F. Holton, Surgeon A. G. Kay, Surgeon R. C. K. Laffan, Surgeon G. S. Lewis, Surgeon C. A. P. Mittchell, Surgeon R. E. R. Morse, Surgeon H. J. R. Moberly, Surgeon-Major S. Moore, Surgeon-Major E. M'Crystal, Surgeon T. Mayne, Surgeon T. C. Nugent, Dr. Ord, Surgeon George Turner Phillips, Surgeon-Major William H. Pickford, M.B, Surgeon A. S. Rose, Surgeon S. Salaman, Surgeon A. T. Sloggett, Surgeon G. E. Twiss, Surgeon T. B. A. Tuckey, and Surgeon T. P. Woodhouse.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Hepatotomy.—Removal of the Uterine Appendages.

The ordinary meeting of the Medical and Chirurgical Society was held on Tuesday, May 24th, Dr. Barclay, President, in the chair. Two papers, by Mr. Lawson Tait, on subjects of considerable interest in connexion with abdominal surgery, were read. Mr. Morrant Baker exhibited a case of bromide of potassium rash.

"On Three Cases of Hepatotomy," by Mr. Lawson Tait (Birmingham). This paper contains the narration of three cases in which the author performed operations on the liver similar to those in two cases already received by the Society. Abdominal section was performed in all three. The liver was found not to be adherent to the parietes in any of them; the contents of the tumours were removed, and the edges of the wounds in the liver were stitched by continuous suture to the edges of the wounds in the abdominal wall, and drainage-tubes were fastened in. Two of the cases were operated upon for hydatids of the liver, and the other for a large cystic abscess enclosing a loose piece of liver tissue, weighing about an ounce, and which had apparently been a slough. All three patients made good recoveries.—Mr. H. Morris was surprised to hear that Mr. Lawson Tait preferred abdominal section to aspiration for unilocular hydatid cyst. During the last few months he had had two cases in which two aspirations had been successful. In one case eighteen and twenty ounces respectively were drawn off; in the other, under Dr. Powell's care, three or four ounces were drawn off by him on the second occasion, and both were, up to the present, cured. He should certainly hesitate to resort to abdominal section at first in such cases. There are no doubt other cases in which aspiration is quite hopeless.—Dr. Heywood Smith asked if there was any troublesome hæmorrhage from the incision through the liver, and whether pressure was sufficient to control it, or whether the vessels could be taken up. He wished to know if sinuses followed the use of drainage-tubes in such cases.—Mr. Hulke thought the great risk was the escape of the contents of the cyst into the peritoneal cavity, and he asked how Mr. Tait quite prevented this. He thought all surgeons must at times have regretted not making freer incisions into hydatids of the liver, especially when suppurating.—Mr. Lawson Tait replied that the hæmorrhage was stopped by pressure. He had had no trouble in now six cases of operation on the liver. He would never again aspirate liver hydatids; he had no fear of abdominal section, but he had fear of aspiration, and he had heard that aspiration rarely cured hydatid cysts. Styrian surgeons especially had this experience. The tapping does not affect the cyst at all, which may at any time refill. In his monocystic case he believed the patient was cured. His assistant seized the cyst with forceps on each side, and placed a sponge on each side, and so prevented any escape into the peritoneum.

"On Removal of Uterine Appendages for the Arrest of Uterine Hæmorrhages," by Mr. Lawson Tait. The author commenced his paper by referring to the use of the statistical method in testing the real value of operations, and especially instanced ovariotomy as one which would not have obtained the complete acceptance it has received had not the careful statistical method of Mr. Spencer Wells shown that its results could be favourably compared with those of every other major operation in surgery. Mr. Lawson Tait wished to lay his experience in another portion of the department of abdominal surgery before the Society, in order to obtain its decision as a guide for the future for himself and others. After protracted trials of drugs for the arrest of uterine hæmorrhage, he had come to the conclusion that all were absolutely without effect, save ergot and two salts of potash, the chlorate and the bromide, and these were by no means uniformly successful in giving permanent relief. In all the cases he had to relate these drugs had been fully tried before the question of operating was discussed. He had entitled his paper "The Removal of the Uterine Appendages," because his experience seemed to show that the removal of the ovaries was not a certain method of arresting menstruation, while removal of the tubes as well seemed to be so. The author then related thirty-one cases, of which four were fatal, twenty-seven recovering from the operation. A summary table was appended to the paper, which was a complete list of the operations and results. The author summed up with the following conclusions, which he considered might be legitimately drawn from them. 1. That, so far as its primary results are concerned, removal of the uterine appendages for the arrest of intractable uterine hæmorrhage is an operation which is quite as easily justified as any of the major operations of surgery. 2. That so far as its secondary results are yet known it is an operation which yields abundant encouragement for its further trial; as conclusions which are indicated but not wholly proved, he thought he might formulate a statement that removal of the ovaries alone is not sufficient to arrest menstruation, but that removal of both tubes and ovaries does at once arrest it. So far as some of these cases have gone the arrest would seem to be permanent. This conclusion is quite in harmony with what is known of removal of both ovaries for large cystomata, for in such cases the tubes are almost uniformly included in the clamp or ligature. Three at least of the cases, and probably two others, show that the arrest of menstruation by this means leads or may lead to the atrophy of uterine myoma. Finally, there is some close connexion, here pointed out, he believed, for the first time, and worthy of very close study, between uterine myoma and its accompanying hæmorrhages and cystic disease of the ovaries. In two of the cases cystic disease seemed to be the cause of the hæmorrhage without any myoma intervening. One other conclusion, he thought, was justified, that the whole subject is worthy of careful study, and should not be made the subject of premature and hostile conclusions. Dr. GRAILY HEWITT remarked that the subject was worthy of the closest possible study. He did not consider that Mr. Tait was in the habit of allowing due importance to conditions, often observed by him to be of moment in these cases, especially the causation of the hæmorrhages. Mr. Tait appeared not to assign any importance to the uterus in cases of hæmorrhage, but takes for granted that when any difficulties arise in the treatment of uterine disease, flexions, &c., the ovaries should be removed.—Mr. TAIT protested that his paper did not give any sanction to such a statement.—Dr. HEWITT said he gathered that from the paper; cases were regarded as incurable except by removal of the ovary, but his own experience was that hæmorrhage is very frequent in cases of uterine displacement, and is curable without removal of the ovary. Two classes of cases are grouped together in the paper: those in which there are tumours of the uterus, and those in which there are not uterine tumours, and in many of which there are displacements and cystic disease of ovary. In the cases of uterine myoma there are some in which this operation is justifiable, although he had seen cure by other means in cases as bad as any quoted. He had seen the other class of cases treated with success without this operation, by dealing with the uterus itself. One of Mr. Tait's cases was under his own care at one time; the patient came to him in a state of intense prostration, great vomiting, emaciation, and was threatened with phthisis; locomotion was impossible; the uterus was decidedly anteflexed. She was three times under his care, and was much better when she left his care, and he hoped to get her quite well; it was anteflexion of uterus with a very soft, relaxed condition of the organ. He could conceive of cases in which this operation was justifiable, but giving Mr. Tait full credit for his skill and for his record, he was sure there were many cases where correction of displacement of the uterus cured the symptoms.—Mr. TAIT said only two cases had flexion, both of which had been under Dr. Hewitt's own care.—Dr. HEWITT thought he heard four or five such cases read out.—Mr. TAIT said in only two cases was the uterus found flexed and replaced and stitched to the wound.—Dr. BARCLAY asked if Mr. Tait wished to recommend the operation where the ovaries were healthy, or only where they were diseased.—Dr. HEYWOOD SMITH said it was very important to recognise the condition of the ovary before the operation. In about sixteen of the cases the ovaries were cystic; the question arose as to whether there was not more tendency to hæmorrhage with commencing cysts in both ovaries than in advanced cystoma. He asked if the hæmorrhage was slight or great in separating the pelvic adhesions of diseased ovaries. He thought very slight alterations in the size, shape, and texture of the ovaries could be recognised before operation, and he thought normal ovaries were very rarely removed in this operation. The cure of flexions no doubt relieved the symptoms directly due to the uterus, but did not affect the ovarian trouble.—Dr. HICKINBOTHAM had seen many of Mr. Tait's cases. He thought sufficient stress had not been laid upon the previous treatment these patients had undergone before the operation. At first he had great doubt about the operation, and shrank from countenancing it; but he felt there were cases, in which hæmorrhage persists and threatens life after all other means have been tried, in which this operation promises a certain and tolerably safe cure. This operation, of course, ought to be hedged about with many precautions.—Mr. LAWSON TAIT replied that he had been told that the operation was liable to abuse, which meant that it would be performed simply for the sake of the fee, or that it would be done to protect women from the possibility of getting children. He thought no surgeon would be found thus to abuse it. This argument, too, was very dangerous. He would like to know how many unnecessary pessaries were applied; and it could be applied in the same manner to many other forms of treatment. The operation will always remain a hospital operation, and it has been quite the most unremunerative of all in his practice. Again, it has been said that it unsexes a woman; but the ovaries removed show that they are so diseased as to prevent bearing children, and the majority of the patients had either been quite barren, or had not had any children for many years, while it does not unfit women for marriage. The patient alluded to by Dr. Hewitt came to him suffering from a severe retroflexion. There could be no real division between ovariotomy and oöphorectomy, as none can say where one ends and the other begins. In one case only had he severe hæmorrhage, which was, however, controlled by pressure of sponges; no adhesions add to the danger of the operation. He never used drainage-tubes in the pelvis.

The meeting then adjourned.

HARVEIAN SOCIETY OF LONDON.

AT the meeting on April 21st, Mr. Henry Power, President, in the chair, Mr. HENRY MORRIS read a paper on Naso-pharyngeal Polypi. He selected six cases which had come under his care within the last few years to illustrate—1. The different kinds of naso-pharyngeal or suffocating polypi. 2. The effects of these growths at different periods of their progress. 3. The various operations which are suitable to the different cases. Of these cases three have occurred in females and three in males. In four of the patients the affection commenced either before or just about the period of puberty. In three of these the polypus was of the firm fibrous variety, two of the patients being boys and one a girl. In the fourth the polypus was of the fibro-cellular kind, being somewhat firmer and tougher than the nasal gelatinous variety. The other two cases (4 and 5) were cancerous in character and occurred in adults. In Case 4 the patient was a man in whom the disease began about the fortieth year, and though of a cancerous nature, and persistently recurring after removal, he continued alive for more than five years; the operations, if they did not cure him, nevertheless kept off death from time to time and restored him, for lengthened periods, to a condition of comfort. Case 5 was also cancerous, and the disease affected a woman when in her fifty-eighth year. It was very rapid in its progress, and ended fatally within a year, the operation having had but little effect in prolonging life, but much in relieving her of very great suffering during the last months of her existence. Four of these cases support the view that the fibrous varieties attack generally young adults, though they do not give colour to the opinion that they are peculiar to the male sex, or that they always exist singly. Case 1, for instance, is opposed to both these views, the patient being a young girl and the tumours being multiple. Nor does this case give any support to the idea, that if these polypi have been persistently removed up to the age at which one no longer finds them commencing, they may be permanently exterminated, unless, indeed, this age is much beyond puberty. For this patient, in whom the disease began when fifteen years and a half old, has now, in her twenty-second year, a recurrence severe enough to prevent her lying down to sleep, and which before the last operation (Feb. 1880) occasionally threatened to choke her. Although we have to wait for adult life before we can expect to find the nature of these growths distinctly cancerous, it still may be considered far from inappropriate to apply the term malignant to some of these fibrous polypi in young boys and girls. Whether we consider the persistent recurrences, the destruction of tissues, the interference with the most important functions of organic life, the frequent hæmorrhages and the disgusting odour, and the decomposition of blood-clot and sloughing parts of the tumour, and finally the general typhoid condition which these several circumstances bring about—these polypi, though slower in effecting their fatal purpose, are as surely malignant in their results as cancer itself.—Mr. **POWER** asked if chloride of zinc, as suggested by the late Mr. De Morgan, had been applied in any of these cases.—Mr. **PYE** thought the fifth case could hardly be termed a naso-pharyngeal polypus.—Mr. **FIELD** asked Mr. Morris if he could recommend any plan of after-treatment to prevent a recurrence of the growth.—Mr. **MORRIS**, in answer to the President, said he preferred the application of the perchloride of iron to chloride of zinc. For after-treatment he occasionally used tannic acid in the form of a snuff.

Mr. **TEEVAN** read a paper on Interference with Micturition, the result of Prostatic Disease. It might be caused by — 1, acute inflammation; 2, chronic inflammation; 3, various alterations in bulk of the lobes of the organ; 4, stone descending into, or originating in the prostate; 5, malignant disease. All the above might in some way or other modify the act of micturition. Acute inflammation might be caused by the extension of gonorrhœal trouble, powerful injections, or tubercular and pyæmic deposits. If the patient could not micturate, an india-rubber catheter ought to be at once introduced, as it was the instrument which caused the least irritation, but it was not always possible to pass it in such cases, and if it failed a soft olivary catheter was indicated. By clearing out the rectum, filling it with ice, and placing half a dozen leeches on the perineum, the inflammation could usually be reduced, and the further employment of the catheter rendered unnecessary. If abscess formed it generally burst into the urethra, but if fluctuation could be detected in the rectum or perineum the knife ought to be at once applied. Chronic inflammation might follow gonorrhœa, or be caused by rectal trouble. The dull aching pain in the perineum and anus, associated with increased frequency of urination, was very wearying to a patient. The application of a few drops of a solution of sulphate of copper (five to ten grains to the ounce) to the prostatic urethra twice a week would usually relieve the symptoms. If it failed repeated blisterings of the perineum would generally effect a cure.—Alterations in size of the different lobes of the prostate: It was of the utmost importance to detect prostatic obstruction early, for if it were not attended to the bladder would become hypertrophied and fasciculated, and the patient condemned to a life of misery. The earliest symptoms of commencing trouble were nocturnal frequency of micturition and the tendency of the urine to fall vertically between the patient's legs instead of being ejected in the arc of a circle. The sufferer might be taught to relieve his bladder night and morning with a soft olivary catheter. It could not be too strongly borne in mind that dribbling of urine in middle-aged and old men meant retention, not incontinence. If the practitioner were armed with a bougie-catheter it was not necessary in cases of retention from prostatic obstruction to diagnose which particular lobe of the organ was enlarged, for the bougie would mount the hypertrophied median lobe, or pass round the projecting lateral lobe. The catheter could then be screwed on to the bougie, and made to follow the latter into the bladder, and so relieve the patient. A stone descending from the bladder might be arrested in the prostate, or have originated there. It was very important to make an accurate diagnosis, for cases had come under his notice which had been treated for retention from stricture where the obstruction was a stone in the prostate. If a metal instrument were not used the mistake might easily occur, for the sensation transmitted by the passage of a soft catheter through a urethra, narrowed by a calculus in it, was almost similar to that conveyed by the instrument when introduced through a tight stricture. When a man, who up to the time of the stoppage had always been able to pass a full stream of urine, was seized with retention, without any premonitory symptoms, the impaction of a stone in the prostatic urethra ought to be suspected. When a calculus was arrested in the deeper portion of the urethra it ought to be pushed back into the bladder with a wax bougie, and then crushed. Malignant disease of the prostate was fortunately very rare. It might not be attended by any pain, and could usually be detected by rectal examination disclosing the existence of a hard nodule in one side of the prostate, and not on the other. This want of symmetry was a most valuable diagnostic sign. The few cases which had come under his notice were all of the scirrhous kind.

The meeting then adjourned.

Reviews and Notices of Books.

A Treatise on the Materia Medica and Therapeutics of the Skin. By HENRY F. PIFFARD, A.M., M.D., Professor of Dermatology, Medical Department of the University of the City of New York, Surgeon to the Charity Hospital, &c. New York: Wm. Wood and Co. 1881. London: Sampson Low and Co.

IN this work Dr. Piffard, who is well known in America as a writer on diseases of the skin with somewhat peculiar views, has made a catalogue of all those drugs which have been described as having a direct or indirect effect upon the skin, and of their observed effects. For the purpose of his digest, which was made originally for his own personal requirements, he has searched widely in dermatological and general medical literature, and subjected himself to much labour, but we confess we are somewhat at a loss to understand for what class of readers the book is intended. Dr. Piffard has of course given prominent expression to his own views of treatment, but beyond that we do not think the work sufficiently exhaustive to be of great value as a book of reference to the specialist, and the general practitioner can find the indications for the treatment of diseases of the skin much more conveniently and completely given in many of the excellent existing handbooks. Without doubt, however, references to the writings of others will be of service.

The book is divided into two parts, and the first part, consisting of 117 pages, is devoted to a description of those drugs, arranged in alphabetical order, which exert an influence on the skin, and of the ways in which they act; the second part, consisting of 200 pages, is taken up with indications when and how to use such drugs, but for this latter purpose Dr. Piffard has written quite a treatise on skin diseases, and prefaced the treatment of each individual disease with its definition, description, diagnosis, etiology, and to some extent its pathology. The description of the ways in which drugs act are grouped under four headings—viz., A, "effects on the healthy skin that follow the ingestion of the drug"; B, "effects produced on the healthy skin by the local application of the drug"; C, "the cutaneous affections in which the drug has been found curative or useful when administered internally"; D, "the cutaneous affections in which the drug has been proven useful when locally applied." Dr. Piffard has made a catalogue of drugs old and new, including both those which have from various causes fallen into disuse, and many indigenous American drugs which are little known in this country. He by no means confines himself to the drugs favoured by so-called "allopaths," but gives us also those in use by other schools, and indeed for many remedies recommended by homœopathists he has a strong predilection, such as for viola tricolor, iris versicolor, hydrastis canadensis, rhus toxicodendron, and as a further instance we may mention that a favourite remedy with him for early syphilis is the hydrargyrum oxidum nigrum Hahnemanni in a state of trituration, in doses of from $\frac{1}{5}$ to $\frac{1}{25}$ grain. And this leads us to say that Dr. Piffard strongly advocates this special mode of administration for many drugs, which has been adopted in our Pharmacopœia in the case of hydrargyrum cum cretâ, such as for arsenious acid, black sulphuret of antimony, calomel, cyanide of mercury, corrosive sublimate, &c., on the contention that minute subdivision facilitates absorption. We cannot help regarding with some suspicion also in this connexion the marked manner in which he goes out of his way to mention the adoption of aconite and belladonna by Liston and sulphide of calcium by Ringer from the homœopathists. Extended as the list is, we may point out as examples of the incompleteness of the catalogue the absence of any mention of the usefulness of benzoic acid in urticaria beyond an incidental reference to a lotion in another part of the work; whilst of boracic acid he says nothing of its healing and soothing action in the form of an ointment. Under delphinium he simply gives a reference to its powers of destroying pediculi, and says nothing about its virtues lying in the oil extracted from the seeds. The account of arsenic is unsatisfactory, and we were much disappointed in finding simply a *résumé* of Hunt's rules for its administration, and of a paper of Dr. Farquharson, where we expected to find a thorough analysis of all that is known of the action of this important drug. And we would remark here that the physiological action of drugs is not fully set forth in this book, and that the latter would have been of much greater service if Dr. Piffard could have seen his way to add to our information as to a more elegant and effective combination of remedies for external application. Thus, under camphor, beyond the statement that it is useful in pruritus (and about this affection we can find no details in the book) combined with chloral, we find no account of its valuable solvent action. Amongst remedies newly suggested or little known in this country, we notice bromide of arsenic for pustular acne (two drops night and morning in an alcoholic solution of one grain in the ounce), and for dusting powders, photographers' graphite, and the officinal phosphate of calcium. Of the value of that old remedy, the *wild and uncultivated viola tricolor*, in acute and chronic eczema, especially in children of a lymphatic habit, Dr. Piffard speaks enthusiastically after twelve years' experience, for he states that, if employed in a proper manner and in suitable cases, its influence is as marked as that of cinchona in malaria or mercury in syphilis; and he is further satisfied by abundant personal evidence that rhus toxicodendron will cut short an acute case of eczema if given at the very beginning, and that "the 100th of a drop of a good tincture, or even a less amount, is not too small a dose to commence with." In treatment generally Dr. Piffard is a keen opponent of Hebra and his disciples, in so far as they hold that skin diseases with few exceptions are purely local; but he guards himself by pointing out to what an opposite extreme the French school has gone. At the end of the work is a formulary, with some new suggestions.

Recueil des Travaux Chimiques du Dr. Domingos Freire, suivi des Recherches sur la Cause, la Nature, et le Traitement de la Fièvre Jaune, par le même Auteur. Rio de Janeiro: Imprimerie de Molarinho et Mont', Alverne.

THE writer of this volume is Professor of Organic Chemistry at the Medical Faculty of Rio de Janeiro, and a Physician to the Hospital of N.D. de la Santé of that city. In his latter capacity he has had the opportunity of observing a large number of cases of yellow fever, and the results of these observations, as recorded by him, are of a very remarkable and interesting character. In the vomit (black, brown, and coffee coloured) of patients suffering from yellow fever, Dr. Freire discovered a great number of bacteria and of round cellular organisms, to which he gives the name of "Cryptococcus xanthogenicus." Studying the life history of the cryptococcus, he found that it presented two distinct phases. In the first it grew from the condition of a small granule, without perceptible structure, into a large cell with a distinct nucleus; this process took from four to five days, and was followed by a stationary period of from a few hours to three or four days. In the second phase conjugation of cells took place, with reproduction of fresh cryptococci, accompanied by the formation of a large quantity of pigment. At the same time bacteria throve and multiplied in the fluids experimented on. Next, comparing the history of the development of the cryptococcus as observed in the vomit, in blood, milk, &c., with the clinical history of yellow fever, Dr. Freire points out that the first stage of the disease, including the period of invasion, lasts from three to four days, which is just the time necessary for the cryptococcus to arrive at the adult state. Further, he has found in the blood of patients during this stage corpuscles with vibriones attached, "adhering to them like leeches," besides others in various stages of deformity or degradation. At the end of this period the blood is profoundly altered, the breaking up of the cryptococci lets loose a large quantity of yellow pigment, which colours the skin, and the fluidity of the blood favours pulmonary and mucous hæmorrhage. The temperature and pulse become normal, or nearly so, and an interval of apparent calm, accompanied by much depression, comes on. This second stage of the disease, like the stationary period in the history of the germ, lasts for two or three days. It is then followed by the third phase of the fever, in which all the symptoms become exacerbated: profuse and uncontrollable hæmorrhages, a weak thready pulse, delirium, and a general ataxic condition with this stage, which is generally fatal. Microscopic examination of the blood of patients in the third period shows, according to Dr. Freire, that "it can hardly be said to be blood which is circulating in the vessels; it is an unformed mass of cryptococcus, bacteria, vibriones, and detritus of all sorts."

Assuming the connexion between the fever and the organisms found in the blood and feeding on it, Dr. Freire fixed upon salicylate of soda, an antiseptic fatal to the growth of germs outside the body, as an agent likely to be useful in treating yellow fever. Viewing the rapid march of the disease he determined to administer the salt hypodermically, and did so with the most successful results. It is impossible to reproduce here the carefully prepared tables given by Dr. Friere, but out of a total of eighty-eight cases treated during the first period (in the first two days of the disease) eighty-three recovered, giving a mortality of about 7 per cent., while of the total number of cases treated the mortality was correspondingly low. The quantity of salt used varied, but injections of from three to eight grains were found effectual, and in some cases from sixteen to twenty grains were used without any inconvenience.

Naturally Dr. Friere writes with some enthusiasm of the results of his researches, which have however only extended through one epidemic; but if future experience should confirm these results there can be no question as to the great value of his addition to curative and pathological medicine. The book is carefully and clearly written, and the work is evidently that of a trained experimenter and observer. Accompanying the text are given plates representing the different organisms described, and their stages of development. We have passed over the first and larger part of the volume, which consists of a detailed account of various chemical researches and speculations, representing a year's laboratory work. These include careful studies of many of the alkaloids, of the processes of fermentation and rancification occurring in oils, &c., and an account of a series of experiments made by Dr. Freire to decide the part played by different gases in the urine. In the last-named paper it is shown that carbonic acid gas and nitrogen naturally present in urine are tolerably active in retarding fermentative changes in that fluid, while the presence of oxygen on the other hand gives a powerful impulse to the process of decomposition.

In his preface the author says that he intends to publish annually, under the form of archives, the complete results of his researches for the year. We trust he may do so, and that his succeeding works may be as valuable as the present, and as honourable to himself and the faculty which he represents.

A Guide to the Examinations at the Royal College of Surgeons of England for the Diplomas of Member and Fellow. By FREDERICK JAS. GANT, F.R.C.S. Fourth Edition. London: Baillière, Tindall, and Cox. 1881.

THIS edition is brought up to date, the latest examination papers are printed, and the several alterations in the regulations are noted; and those who find such information as is contained here of service will be grateful to the author for this revised edition. We are reminded, however, by its appearance that the truly successful guides to these examinations are the dissecting-room, physiological laboratory, and the wards and post-mortem room of a hospital.

New Inventions.

McKESSON & ROBBINS' CAPSULE PILLS.

WHEN we compare the small and silvered pill or the pleasant Pharmacopœial lozenge of this period with the bolus of thirty years since, we have a distinct sense of progress. But there is still a large field for invention in this department. We have before us a case of capsule pills—the work of Messrs. McKesson and Robbins, manufacturing chemists of New York, which show that our druggists will have in their brethren of the United States no mean competitors. These preparations are so full of taste and neatness as to give the medicines an inviting appearance instead of a repelling one. The case can be carried in the pocket or in the carriage, and a dose of any much-needed medicine administered without delay. The pills are of various sizes, some a little too large; but all are smooth and bead-like, and can be easily received by either the mouth or the œsophagus. The preparations are well worthy of trial. Those before us include capsule pills of sulphate of quinine, 1 gr. or 2 gr.; sulphide of calcium, ¼ gr.; podophyllin, ¼ gr.; pepsin, 1 gr.; pil. colocynth. co. (B.P.), 5 gr.; muriate of morphia, ⅓ gr.; ergotine, 3 gr.; &c. The agents of Messrs. McKesson and Robbins in London and for Europe are Messrs. Burroughs, Wellcome, and Co., Snow-hill.

A VACCINATION POCKET-CASE.

THE time is opportune for noticing a neat little case by Messrs. Salt and Son, of Birmingham, with compartments for holding tubes of lymph from any given child, and a corresponding ivory space outside it, on which the name and date can be written. The case contains also an instrument for vaccinating. In the instance before us the instrument is slightly too long for the case, and has been injured in the point. This should be made an impossibility. The case, too, it seems to us, might be constructed of lighter material. With these qualifications, it is one of the most useful little articles which a practitioner can have.

A NEW POCKET OBSTETRIC CASE.

MESSRS. ARNOLD & SONS have arranged a pocket obstetric case for Dr. Murphy of Sunderland. It is made of leather in steel frames, like an ordinary cigar case. It contains a hypodermic syringe, bottles for ether, ergot, ergotine, and morphia, together with a pair of scissors and a pocket for ligatures, &c. The case is a very convenient one, and an improvement upon the one ordinarily used.

CLINICAL TEACHING AT ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

To the Editor of THE LANCET.

SIR,—There is a statement contained in the letter of "A Cambridge Undergraduate" in your issue of May 14th which requires some explanation. He states "that the majority of Cambridge students know no more of practical medicine and surgery after four years' attendance on the practice of Addenbrooke's Hospital, than an average London student knows after the first six months of his attendance in the wards of his hospital." Now, anyone of experience in such matters will agree with me in saying that the knowledge of medicine and surgery of the average student after his first six months in the ward is not very deep. He has, perhaps, learnt to diagnose a fracture or a simple tumour, is familiar with the ordinary surgical appliances and their practical use. Of the treatment of surgical cases he probably knows but little, while his knowledge of medicine is certain to be quite as limited. Now, "A Cambridge Undergraduate" asks us to believe that a large number of students after four years' attendance at a hospital of no inconsiderable size, abounding with cases of great interest, both medical and surgical, acquire no more knowledge than this.

As a matter of fact few Cambridge students of medicine occupy four years in attending the practice of their hospital; the majority, I think, spend about two, after which they proceed to the larger London hospitals, where they obtain a more extensive field for observation and study. It must also be borne in mind that during these two years they are placed in much the same position as the first and second year's students in London hospitals, their mind and reading being mainly occupied in preliminary scientific work, while they attend the practice of the hospital in accordance with the regulations of the examining bodies. Any student, however, who feels an interest in his work, and attends the medical and surgical wards of a general hospital, cannot fail, even in two years, to acquire a good deal of general knowledge, if he have not the advantage of systematic teaching.

At Addenbrooke's Hospital not only is there ample opportunity for observation, but also a regular amount of clinical teaching well suited to the knowledge of medicine and surgery which the students possess, delivered by men well able to perform the task they take in hand, in some instances by those whose names, as household words in the annals of the profession, are more than sufficient guarantee for the excellence and thoroughness of their clinical instruction. As a practical fact the students who come from Cambridge to the London hospitals are generally quite as advanced in their professional work as London students at the same period of their career. This is evidenced by the large number of Cambridge students who are at once advanced to the posts of dressers and clinical clerks on their arrival at the London hospitals, and who afterwards obtain the more valuable house appointments at those institutions. It is, of course, quite obvious that no amount of opportunities for observation, no clinical teaching, however excellent, can make a student possess a knowledge of medicine or surgery when he neither knows how to observe facts or to argue from them. An hour's lounge round the wards of a hospital three days a week will by itself no more teach a man surgery than the same time spent in a picture gallery would teach him to become an artist. I hope to have shown that want of practical professional knowledge is not a fault of the majority of Cambridge students when they go up to the London hospitals. The minority, with whom "An Undergraduate" seems more personally interested than myself, must not blame the clinical teaching of an excellent provincial hospital for what is really the result of their own idleness and neglect of opportunity. I am, Sir, yours, &c.,

May 23rd, 1881. MEDICUS.

COLLEGIATE LECTURES.—Professor Gerald Yeo, F.R.C.S., will commence his course of three lectures, "On the Contractile Tissues," in the theatre of the Royal College of Surgeons, on Monday, June 6th. Professor Jonathan Hutchinson, F.R.C.S., will commence his course of six lectures, "On the Laws of Inheritance in Relation to Disease," on Monday, June 13th.

THE LANCET.

LONDON: SATURDAY, MAY 28, 1881.

THE artificial attenuation of the virulence of the morbid agents which give rise to acute diseases is a problem of profound practical importance, opened up by the pathological investigations which have recently been undertaken in France. These researches, to which we have from time to time called the attention of our readers, and which have added new lustre to the somewhat faded reputation of French medical science, are due to the personal labours and inspiring example of M. PASTEUR. The special subject of the artificial weakening of the virulence of these poisons is the subject of an article by him and MM. CHAMBERLAND and ROUX in a recent number of the *Gazette Médicale de Paris*. The facts, very ably discussed by them, are of such importance as to deserve detailed description. Recent experiments have shown that the attenuation of a morbid virus is possible. Consisting as it does of a special organism of extreme minuteness, it is susceptible of artificial culture, by which, even though all external contamination is precluded, more or less considerable modifications in virulence take place, apparently under the influence of the oxygen of the air. The inference from these experiments is that the rational means of prophylaxis against these acute diseases is to endeavour to prepare from an active virus a vaccine virus of restrained development, capable of preventing the fatal effects of the former. Hence the great object of their researches has been to ascertain as fully as possible the conditions under which the oxygen of the air can exercise this effect.

The virus of anthrax, which has been so carefully studied, was the first object of investigation. The experiments on chicken-cholera are well known. But between the virus of the two diseases there exists a difference which prevents the vigorous application of the results obtained with one to the other. The organism of the chicken cholera does not appear to be resolvable, by culture, into definite germs. Only cellular elements, multiplying by fissure, are discoverable, and the conditions under which true germs are formed are unknown. Ordinary yeast is a striking example of such cell forms, multiplying indefinitely without any appearance of their spores of origin. The mycelia of many fungi in certain conditions give rise to the collections of cells called conidia, which, detached from their sources, seem to reproduce the organism under the forms of cells without any spore structures being discoverable. They are comparable to the plants which are reproduced by buds, and the seeds of which are not commonly employed for their multiplication. The bacteria of anthrax, however, behave differently in artificial cultivation. The filamentous mycelia have hardly continued to grow for twenty-four or forty-eight hours when they are found to be transformed (especially those in the freest contact with the air) into refracting ovoid corpuscles, which gradually become isolated, and constitute veritable germs of the minute organism. Observation shows that the vitality of these germs, so quickly formed under cultivation, is not rendered less by the influence of the atmosphere, nor are they rendered less virulent. M. PASTEUR possesses a tube of the bacteria of anthrax, preserved since March 21st, 1877. Each year he has tested the germinal power of the minute corpuscles, and each time germination took place with the same facility and the same rapidity as at first. Each year the virulence of the new cultures was tested, and it was found on every occasion to be undiminished. This fact seems opposed to the theory that the oxygen of the air can lessen the activity of the virus of anthrax, but M. PASTEUR suggests that the solution of the difficulty is to be found in the very rapid multiplication of the germs of the bacteria. Is not the organism in its filamentous form and its fissiparous multiplication the same as that of chicken cholera? It is readily intelligible that a germ should undergo no modification under the influence of the oxygen of the air, and that any change in vitality, of which bacteria are susceptible under this influence, they undergo while in the stage of mycelium. A bud left on the ground in contact with the air would soon lose all its vitality, while a seed under the same conditions would preserve all its power of reproducing a plant. Hence for the oxygen of the air to produce its effect it is essential that the organism should be exposed to it in the state of mycelium under conditions in which germs shall not be formed. How can this condition be secured? By several artifices the appearance of spores in the artificial cultures of the bacteria of anthrax can be prevented. By keeping the temperature at the lowest point at which the cultivation will go on—that is, about 16° Centigrade—the bacteria do not form germs, at least for a very long time. The organisms at this temperature assume irregular shapes, but do not form spores. The same is true when the culture is made at as high a temperature as is compatible with the process, the exact degree varying according to the medium. In neutral decoction of fowl the culture does not go on above 45° Centigrade. It takes place freely at 42° or 43°, but without the formation of spores. Cultivated at this temperature, with free contact of pure air, there is an abundant production of mycelium, but no spores are formed, and after a month of such culture the organism seems to be dead. Sown in fresh decoction of fowl, it appears to be completely sterile. The vitality of the organism is lost suddenly. The day before it is found to be completely sterile it is capable of reproducing itself with the greatest facility. The facts as to its condition of virulence are equally remarkable. After eight days of such culture at 42° or 43°, the virulence is lost, at least the inoculation is ineffective in the case of the guinea-pig, rabbit, and sheep, three animals which contract anthrax with the greatest readiness. It thus seems that by simple culture we are in possession of the means not only of weakening the virulence of the poison, but even of completely arresting it.

What happens during the first eight days of culture thus to remove all the disease-producing power of the organism? It may be remembered that the organism of chicken-cholera also perishes in successive culture under exposure to the oxygen of the air. The time is, it is true, long, but in the intervals a progressive attenuation of virulence is manifest. This fact suggests that in the case of the bacteria of anthrax a similar diminution of virulence occurs before it becomes extinct, and such is found on experiment to be the case. Before the extinction of its virulence, a progressive attenuation may be demonstrated, just as in the case of the organism of chicken-cholera. Moreover, it has been found that one attack of anthrax confers immunity against subsequent attacks, and each example of the weakened virus seems to confer the same immunity. By the inoculation of the cultivated organism, M. Pasteur has succeeded on a large scale in conferring immunity upon sheep, and has thus verified in a different and most important manner the results obtained by M. Toussaint.

There is another problem of great importance connected with this subject, and that is the possible return of virulence in the organisms rendered feeble by successive cultivation. The bacteria of anthrax is rendered inoffensive for the guinea-pig, the rabbit, and the sheep. Can it regain its activity? It is found that the cultivated virus is not equally inoffensive to guinea-pigs at different ages. That which may be inoculated without the least risk in a guinea-pig more than six days old, will kill with certainty one that is only a day old. If, from a newly born guinea-pig, another is inoculated, and from this a third, and so on, the virulence of the bacteria is progressively reinforced, and soon it is found to be capable of killing a guinea-pig three or four days old, then one a week old, until animals several months and even years old succumb; and, lastly, it is capable of causing the death of sheep. The organism has reacquired its original virulence, and it preserves this renewed virulence indefinitely unless means are taken again artificially to attenuate it. Similarly, the organism of chicken-cholera, when it has lost its virulence for fowls, will still kill small birds, such as canaries, and by successive inoculation of these the original virulence may be restored, so that it has the same action as at first upon adult fowls.

These facts with regard to the return of the morbid influence are of extreme interest as regards the etiology of contagious diseases. M. Pasteur suggests that the attenuation of the contagium under the influence of the air may be one of the factors in the cessation of epidemics. The facts just related may perhaps explain the apparently spontaneous recurrence of such diseases, the virus undergoing intensification under certain conditions. He instances the outbreak of plague in Benghazi in 1856–8, the commencement of which could not be traced to contagion. In the habitat of plague the attenuated virus may always exist, ready to resume its active form when the conditions of climate, famine, &c., recur. So, too, with camp typhus and other diseases which appear spontaneously in all countries. The germs of the organisms which cause these diseases are no doubt widely spread, and are innocuous unless their virulence is augmented by special conditions of development. Organisms may be inoffensive to man, or to this or that animal; but it is quite possible that, in some of the thousands and thousands of species of animal beings, the same organism may produce disease. Their virulence, reinforced by passing successively through many individuals of this species, may become capable of affecting other animals, and even man. Thus a new virus and a new contagium may arise. It is possible that such has been the origin of many contagious diseases, as small-pox, syphilis, plague, yellow fever, and we may add especially of diphtheria.

The facts observed when inoculation of small-pox was practised introduced into science an opinion the opposite to this—namely, the possible diminution of the virulence by the passage of the poison through certain subjects. Ther is nothing inconsistent in the two views, and the latter, which was held by Jenner, is not improbable. Hitherto, however, no other examples of this have been met with, although carefully sought for.

Few natural laws are more widely known or more generally abused than that expressed in the aphorism, "every part of the animal body grows by exercise." The brain is part of the body—*ergo*, it grows by exercise, and, by a facile fallacy of inference, the more it is exercised the more it will grow. Whereas, although it is of course true that the organ of the mind forms no exception to the law of "development by use," it is only in a very limited sense the fact that brain-work promotes brain-growth, and it is of the utmost importance that the precise conditions under which it so acts should be generally understood.

The brain does not grow in bulk or weight after a comparatively early age. Before the period of physical growth is completed mental-straining would be like racing a two-year-old colt, and almost inevitably issue in a break-down; and subsequently to that period there can be no question of increase in the quantity of brain-cells or molecules; the limits of development as to mass, though perhaps not as to weight, are then finally determined. The only physiological opportunity for development which remains after the age of childhood relates to the development of special qualities, capacities, or properties in the cerebral elements. Any rough application of the principle that growth is stimulated or in any way promoted by exercise, must therefore be inadmissible in brain-culture during youth. Growth is not the end to be attained in this stage. The object to be gained is the internal arrangement of brain-molecules, under the reflex influence of special processes of activity. The means to this end is training as distinguished from mere exercise. This is an important discrimination. It is not work for mere work's sake that is wanted to cultivate the brain of a youth, but a skilful eliciting of cerebral function by education tending to formulate the energy of brain-tissue by leading or constraining it to useful lines of action. Brain-tissue is, so to say, a more costly part of the organism than any other; it is less easily repaired than other tissues, and needless waste by consumption in purposeless use is to be deprecated. Brain-work is only of use so far as it *trains;* it cannot promote growth, for the simple reason that growth after the earlier years of life is physiologically impossible. The measure of brain-growth is practically fixed by hereditary force, and this force operates more powerfully in regard to brain-tissue than to any other element of the body, so that mischief is peculiarly likely to result from abuse of the known laws of "development" in respect to this particular organ.

It follows from these general considerations that those who have the care of youth, and persons in authority who by their official regulations determine the nature and course of the educational process to which the young are subjected, should so limit the exercises they impose or enjoin, as to minimise the expenditure of energy; while securing that, when put forth, it shall be so controlled as to *lead out* the faculties of the mind in healthy and useful directions. A well-developed brain implies a well-ordered mind; without order the intellectual powers can never be strong in action, and are always likely to break down, or prove self-destructive. The method of education which seems to find increasing favour with the preceptors of youth, and which is distinctly encouraged by the mischievous system of competitive examinations now ruthlessly forced on the population by enthusiastic but short-sighted legislators, is most disastrous; it disregards the main purpose of mental culture—namely, training—and treats the brain as it would treat a muscle, seeking to force its growth by exercise. The popular notion would appear to be that any fairly intelligent youth must benefit by *work;* whereas every exercise he performs involves an expenditure of cerebral tissue which cannot be replaced. Muscle may be replaced because it is, so to say, all of a piece. It is not permanently stamped with the impress of any act which it has performed. The cells or molecules of brain-tissue are permanently impressed by the use made of them. Every fact "committed to the memory" is impressed on some molecule, or set of molecules, and these afterwards form the physical basis of the record retained. Doubtless there is a wondrous power of adaptation in the brain, which enables it to perform the most complex acts of mental function, and the impressable particles of a healthy cerebrum are abundantly sufficient for a long life of intellectual activity; but the supply is not unlimited, and by excessive or disorderly "work" in youth, the mental capacity may be so squandered that when adolescence or full manhood is reached there will be no power to make new acquisitions of knowledge, and barely any opportunity for improvement in regard to the stock of information possessed.

———

Before the age of seven nothing ought to be attempted in the shape of "teaching" except what may be taught indirectly by example, or, almost unconsciously, in the ordinary communication of impressions. The sole aim of the educator should be to develop by habit the faculties of observation, and mind-storing, with the closely connected power of recalling mental impressions at will, which we call "memory." The simplest processes of inductive reasoning may be developed *practically*, by suggesting lines of thought to the child-mind, but there should be no teaching, properly so called. Subsequent to this stage—*i.e.*, the stage of brain-growth—economy of mental energy is not less important than the guidance of such force as may be liberated, or exercised, on lines calculated to develop and train the faculties for useful work. There are exercises which are needful for what seem to be purely educational purposes—that is to say, for the effects they produce on the mind or brain, reflexly. For example, the dead languages, the higher mathematics, and perhaps logic, are chiefly valuable for the influence they exert in eliciting and training certain faculties or forms of thought. Such exercises are, in a practical sense, among the most important to the future integrity and efficiency of the brain which the educator can employ. The mere accumulation of what is called knowledge is not brain-training, but brain-burdening, and may easily be pushed to the extreme of brain-straining, with the result of a complete and ruinous break-down. This is especially likely to arise when, as often happens, there has been little or no wise training in early boyhood, and the mind or memory is severely taxed for examination purposes later in youth.

———

A multitude of cases might be instanced in which boys who have not been trained for intellectual exercises at the outset of life have been urged or lured to make a great effort, and have been mentally ruined in consequence. No care bestowed on the *manner* of work can suffice to compensate for an original lack of power, or obviate the effects of a disorderly constitution, of the intellectual apparatus and functions. It is no more possible to make an intellectual giant of a mental dwarf than it would be to develop a Hercules out of a mannikin. By the artifice of mind-forcing and "cramming," the *memory*—a low-class faculty often prominently developed in the case of idiots—may be made to retain for a time the necessary material for exhibition at some examination-table; but if the undeveloped mind is incited to *intellectual* action in the process, the result must be untoward. The untrained boys who survive the process of forcing and cramming, and retain their mental health, are for the most part those of somewhat obtuse and insensitive cerebral capacity, who take in their knowledge as beasts of burden carry a load—without either interest or worry. A sensitive boy, who has been untrained, will feel his inefficiency so acutely while his memory is being loaded with unappropriated information, that he will fret and worry until he falls ill, either before or after the requisite quantity of "learning" has been deposited in his memory. There can be no such thing as *real* brain-work without power, and such power implies mental training following upon healthy growth. It is in practice a grave error to suppose that any brain may be developed by mere exercise. The result of an attempt to develop it by this agency—especially in advanced youth—is more likely to ruin than to improve it.

◆

AT the last meeting of the Royal Society, Dr. MACEWEN presented a paper on a case in which he had successfully transplanted bone. The patient was a child four years of age, who had lost two-thirds of the shaft of the humerus by necrosis fifteen months previously, and in whom no osseous repair had occurred. The limb was of course useless. Dr. MACEWEN proceeded first to make a groove in the soft tissues in the position of the bone, relying for this on his anatomical knowledge, and then placed in this groove small fragments of wedges of bone removed from other patients for curved tibiæ. The result has been that a good new bone has been formed, the new portion has united firmly to the upper epiphysis and lower part of the original shaft, and the bone is only half an inch shorter than its fellow. Proper care was taken throughout to have the parts perfectly aseptic. Great interest attaches to this case, which is the first of the kind recorded, and Dr. MACEWEN is entitled to warm praise for devising and carrying to such a successful issue the many details necessarily involved in its management. Happily Nature is usually so skilful in the repair of lost parts of bones, that it is not often the surgeon is called upon to make good the loss; but much as there is to marvel at the way in which Nature thus generally plays her part, cases now and then occur in which she fails to supply the lacking portion. Many interesting problems arise in reviewing the facts of this case. The first is, What was the original condition of the limb? There was evidently a local inability to produce a new bone, and we may presume that in the primary inflammation the periosteum, or at least the deeper active portion of it around the sequestrum, had been destroyed, and the lymph poured out from the surrounding tissues lacked any "ossific stimulus." This the bone-grafts supplied. But how are we to explain the formation of new bone of the proper length and form? We cannot, of course, attribute this power to the transplanted tissue; it might have seemed probable if Dr. MACEWEN had used pieces of the opposite humerus, or even any humerus, for his purpose, but we find that pieces of tibia were successful. If not the transplanted bone, are we to say that the ends of the original bone exerted a moulding influence on the ossifying material, or was it the effect of the surrounding tissues? A question naturally arises whether transplantation of bone is essentially better than transplantation of periosteum alone. It is easy to see that when whole pieces of bone are used, the periosteum over them will be probably more active than when stripped off and used alone, as in stripping off it is liable to injury. It would also be exceedingly interesting to know what actually became of the transplanted bone. Did the medullary cells and soft parts live, and the fragments become actually incorporated with the new bone; or was lymph effused around and into the bone, which was then gradually softened down and absorbed, or cast away in secretion? The problem is the same as has been raised about organising blood-clot. A case published in our columns in 1878 by Dr. MACEWEN may be taken as throwing some light on the question; there, in a case of compound fracture of the leg, a fragment two inches and a half long was completely detached, except by a very few slender bridges of periosteum, but being replaced and carefully treated, it was seen after four weeks to become injected with blood, and granulations rose from its surface. Here the whole process was closely watched from day to day, and the large fragment was seen to become firmly incorporated again with the rest of the bone. Other cases, individually perhaps less conclusive, point to the same conclusion; we may refer to one contributed to our columns in 1877 by Mr. PORTEOUS. As so frequently happens in such cases, while Dr. MACEWEN has been carrying his case to a successful issue in Glasgow, a similar proceeding had been determined upon by Mr. C. MACNAMARA of the Westminster Hospital. On Wednesday last we saw him plant several small fragments of bone taken from an amputated metatarsus in a groove prepared in the leg of a little child from whom several months ago he had removed the greater part of the shaft of the tibia. This operation was determined upon and discussed before the class of students more than a month ago, before Dr. MACEWEN'S case was made public, but it was postponed until the patient had had a few weeks' change of air in the country. Mr. MACNAMARA remarked, in reference to it, that he had been greatly struck with what he had seen in the practice of Mr. THOMPSON, who has removed teeth and replaced them several hours later, and they have adhered firmly in a few days; this, with other facts, had encouraged him in his endeavour to make a new bone in the case in point.

◆

THE Royal Commission on the Medical Acts has the power to sit with open doors or with closed ones. It has preferred the latter alternative, and refuses to admit even the Medical press, which has certainly some claim to be kept *au courant* with the proceedings of the Commission. We are not prepared to deny that this action of the Commission is in accord with the practice of Royal Commissions. We are not the more enamoured with their decision on this account. The inquiry is one of great interest to the public and to the medical profession, and the day has gone by for close inquiries. The Royal Commission is not compelled to exclude the press. That there are precedents for doing so is not a sufficient justification. The sooner mere precedent is disregarded in favour of considerations of reason and common sense the better for this mode of inquiry, which has no more claim to be conducted secretly than any other inquiry into public matters affecting nobody's personal character. We can only urge our respectful protest against this step on the part of the Commission, accompanied, as it is, by the withholding of all information to outsiders.

It will be very interesting to see how the Commission proceeds in respect of taking evidence. Much most important evidence has been given already before a Select Committee, which the Commission will have the power of regarding as evidence taken by itself. But it is impossible that evidence so taken can have the effect of oral and living testimony, and those witnesses who have been already examined will be at a considerable disadvantage as compared with those to be examined by the Commission; for we believe it is intended to examine some further witnesses. It is most unfortunate that the proceedings and plan of the Commission are to be kept secret. We can only acquiesce with as much grace as we can command, and not without some hope that the Commission even now, before commencing serious business, will reconsider its decision and admit the press—a step which may have some inconvenience, but has far more advantage even to the Commissioners themselves.

Annotations.

"Ne quid nimis."

THE DUKE OF ALBANY ON HOSPITALS.

THE speech which Prince Leopold delivered at the University College Festival on the 20th inst. showed, as do all his public utterances, how deeply and thoroughly his Royal Highness is accustomed to consider questions of genera interest. The claims which the hospital has upon the wealthy dwellers in Bloomsbury, Marylebone, and St. Pancras were clearly shown. During the past year 2789 in-patients were relieved, and over 22,000 out-patients paid some 65,000 visits. This means, as his Royal Highness put it, that about 400 different sick persons daily receive relief. Notwithstanding these figures, it was shown that the staff was sufficient for the accomplishment of the work, and thus the excuse for non-contribution, which is so often put forward, that the patients are necessarily "scamped," was not left as a refuge for those whose discretion is greater than their generosity. The touching allusions to the fact that the Prince himself had in his lifetime learnt how to appreciate the medical art, and his grateful acknowledgment of the labours of Sir William Jenner which were personal to himself, are not likely to be forgotten by those members of the profession who were present, or who read the speech in the newspapers. The Duke of Connaught also, who had graciously volunteered to support his brother upon the occasion, made, in replying to the toast of "The Royal Family," a generous acknowledgment of the services rendered to them by more than one member of the staff of University College Hospital. The dinner was a great success, although we could have wished that the total of the subscriptions had reached a figure more worthy of the occasion.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.

THE last list of candidates to be balloted for, or petitioning for admission to the Fellowship, numbers fifteen. Six of these are licentiates of Edinburgh, and nine have surgical diplomas from other corporations. It is to be hoped that this branch of trade in the Scotch Corporations will receive attention, as Mr. Mundella promised it should, from the Royal Commission now beginning its work. Not the least unsatisfactory part of this system lies in the names by which the applications are backed, including some of the very highest in Scotland and England.

TIGHT-LACING.

LAST week a verdict was returned by a coroner's jury which is quite as applicable to not a few cases of premature death which do not happen to be made the subject of medico-legal inquiry. It is difficult to speak with moderation of the folly of tight-lacing in view of such facts as this, especially as no attention seems ever to be paid to the warnings repeated *ad nauseam* against irrational and unhealthy modes of dress. Physiology does not enter into the sphere of the "fashions," the follies of which are productive of more suffering and ill-health than people are willing to concede. In spite of satire on one side and admonition on the other, there seems to be but little diminution in the degree to which these vagaries are carried, as may be proved by anyone who walks abroad during the height of a London season. Why is it that in this matter of "tight-lacing" there should be such tenacity, for there is hardly any subject that has been so unmercifully and yet so necessarily criticised as this? There are only two possible reasons for its maintenance—the one that it is indispensable to the present form of female attire, and the other that it is believed to lend grace to the wearer. Neither of these contentions can seriously be maintained in the face of the known evils which follow the practice, but they are at present ideas so firmly rooted in the female mind that their dislodgment is not easily effected. Now and then, indeed, there seems to be an attempt to introduce a more rational style of dress, but such attempts are rarely successful, owing in great measure to the disposition to ridicule new departures which do not harmonise with the "mode." The medical profession has never ceased to express its opinion upon the evils of tight-lacing, being well aware of the derangements for which the practice is responsible. To be effectual, however, such remonstrances must be given not only to those who follow the practice, but to those who either tacitly or openly encourage it. We are treading, we know, on delicate ground, but it is time there should be plain speaking, even at the risk of giving offence, for it must be confessed—and it is no disparagement to the fair sex to admit it—that so long as men persist in regarding an unnatural deformity as a beautiful object, so long will many women do their utmost to become "beautiful," no matter how painful the ordeal to which they will have to submit. A well-known writer upon female dress not very long since admitted that it was the object of women so to dress as to render themselves attractive to the opposite sex, thereby following out a law which obtains throughout animal creation, and of which there is no denying the truth. But the same author spoke out boldly against the practice of tight-lacing, showing that in her opinion, at any rate, the practice was not essential for the purpose above stated. In all seriousness, it is a pitiful thing that in these days, when all our youth can obtain an insight into the principles of physiology, there should still prevail a practice so unphysiological as that of which we speak. It stands to reason that long-continued, firm compression of the lower ribs cannot be indulged in with impunity. The dorsal, thoracic, and abdominal muscles are rendered feeble from enforced inactivity, respiration is impeded, circulation is carried on under greater strain, and the viscera are displaced to a remarkable degree. In the case which forms the text of these remarks, not only was the liver deeply indented and displaced, but the stomach was constricted into two portions, and both of these effects have often been observed before. The affections attributed to tight-lacing are many and various—some perhaps without sufficient ground; but most certainly respiratory, circulatory, and digestive derangements, not to mention difficulties and dangers in parturition, are directly traceable to tight-lacing. Such derangements lead the way to other and graver changes; they may cause many ailments which render life a misery, or may eventually lead to the premature extinction of life—not perhaps directly, but by rendering the organism unable to cope with disease, however arising. Once more, then, we urge the female members of the community to abandon this fatal article of attire; its utilitarian purpose could no doubt be supplied by means at once more simple and less injurious; and its æsthetic function exists only in the imagination, being grounded on the false and perverted notion that the natural contour of the body is ungraceful, whilst the deformed, contracted "waist" is considered beautiful in proportion as its constriction is extreme.

EARTHWORMS AND ANTHRAX.

AN important report was presented to the Académie de Médecine, at its meeting on the 17th inst., by M. Villemin, in the name of a commission appointed to investigate the statements of M. Pasteur as to the presence of the germs of anthrax-bacteria in the soil, and their transportation by earthworms, statements which had been contradicted by M. Colin of Alfort. In the investigations of the commission they first inoculated five guinea-pigs with earth taken from the soil over a trench in which animals dead of anthrax had been buried twelve years previously. All the guinea-pigs died, the first four from septicæmia, the fifth from well-marked anthrax, and the latter presented numerous bacteria in the blood of the heart and the spleen, which organ was considerably enlarged. A second similar series of guinea-pigs were inoculated with earth from above a pit in which animals dead of the disease had been buried for three years. The first four of these also died of septicæmia, and the fifth of anthrax, with characteristic bacteria. A third series were inoculated with "virgin soil"—i.e., earth from a spot in which, "within living memory," no animal dead of anthrax had been buried. All of these continued well, presenting only at the point of the inoculation a small nodosity the size of a nut, and consisting of an abscess enclosed in a pyogenic membrane. The first two of these experiments with the suspected earth were repeated, six guinea-pigs in all being inoculated. Of these all died, five of septicæmia, the sixth of anthrax. Two other guinea-pigs were inoculated with blood from the animals to which anthrax had been communicated in the first two series of experiments, and both died of the same disease. A drop of blood taken from the ear of one, and "sown" in some decoction of fowl, reproduced pure and abundant anthrax-bacteridia. Some worms were also taken from the earth over the pits in which the animals had been buried three and twelve years before, and their excrement (the worms being still alive) was diluted with a little distilled water, and with it three guinea-pigs were inoculated. Of these two died from septicæmia, and the third from anthrax. Other three guinea-pigs were inoculated with the excrement of worms taken from soil beneath which, during the Commune, human bodies had been interred. One of the guinea-pigs died from septicæmia, the other two continued well. Lastly, the excrement of worms collected over the trench in which the animals had been buried for twelve years, and treated by "cultivation," gave rise to a rapid production of bacteridia, which, inoculated into two guinea-pigs, caused the death of both by anthrax. The experiments and report thus give a triumphant corroboration to the assertions of M. Pasteur.

LICENSED LODGINGS AT CAMBRIDGE.

WE are pleased to find the question of providing suitable and wholesome accommodation for the increasing number of undergraduates at the University of Cambridge has become a subject of discussion in the columns of the Cambridge press. For some time past the lodging-house accommodation of the town has failed to keep pace with the natural growth of the University, and consequently houses never intended, and utterly unsuited, for the purpose, have been brought into requisition. There can be no doubt many of the smaller lodgings, especially in the outskirts of the town, are unwholesome, if not actually dangerous. The drainage at Cambridge, as is well-known, is extremely defective; indeed, its sewers have been described as "elongated cesspools," and therefore, unless effective measures are taken, sewer-gas finds a ready access to the houses. Have we any assurance that these measures are taken? The medical officer of the town has, we know, done much to secure a more efficient ventilation of the sewers of the town, and thereby has considerably lessened their dangerous tendency, but his powers stop short at the houses. Here, however, the University assumes the responsibility. No lodgings are to be let to undergraduates unless they receive a licence as to their sanitary character from their inspector—a clergyman! From what we have ourselves seen, and from reports we have received, we do not think this gentleman is very exigeant with regard to the sanitary arrangements. No doubt, under existing circumstances, it is impossible to be so; if he were, a considerable number of freshmen would have to stay down every October term till suitable rooms became vacant. As a fact, however, they do not; they are all lodged somewhere and somehow. How defective some of these smaller lodgings are will be shown by quoting some suggestions recently made in the *Cambridge Review* for their improvement. The walls, the writer says, should be of sufficient thickness to resist the attacks of all weathers. The waterclosets should be appointed on the most approved plan, well ventilated, and amply supplied with water. A receptacle for dust and ashes and other refuse should be placed as far as possible from the house, and emptied as frequently as possible. Every licensed lodging-house should be compelled to have a larder built accessible to plenty of air, for the preservation of the students' food. These are simple but necessary requirements, but we venture to say we could point out many licensed lodgings where none of them are fulfilled. The writer in the *Cambridge Review* proceeds to urge that all cesspools should be abolished, and that all wells and pumps on the premises should be closed. Certainly, and this ought to be attended to at once; it would be most reprehensible on the part of the University authorities if they afford an opportunity for this suggestion being made again, and we hope the instances where such conditions exist are not at present numerous. Knowing the vigilance exercised by the medical officer of health, and this comes under his department, we should think this cannot be. We are not sanguine, however, under the present system of University sanitary inspection, that any great improvement can be effected even in less important details. We therefore earnestly advise parents whose sons have to live in lodgings to see for themselves that these are both habitable and wholesome, and not trust too implicitly to the sanitary acumen of the reverend licenser.

TUBERCULOUS PERICARDITIS.

TUBERCULAR inflammation of the pericardium is a very rare lesion. Laennec only met with two instances of it, and Louis but one. Although cases have been from time to time recorded in medical literature, their total number is not large. Grey granulations in the pericardium have been met with in cases of general tuberculosis in children, unaccompanied by actual inflammation, but the condition of tuberculous pericarditis is most uncommon. An instance of the affection in a girl of nineteen has been lately recorded by Dr. Vaillard in the *Journal de Médecine de Bordeaux*. The patient died from tubercular meningitis, with extensive enlargement and caseation of the lymphatic glands. The parietal and visceral layers of the pericardium were connected by soft adhesions, and each was covered by false membrane; the visceral layer was studded with granulations and small nodules of caseous tubercle. At a distance from these nodules the microscopical examination showed the proper tissue of the membrane to be somewhat thickened and continuous with a new membrane on the surface, which was almost perfectly organised. Sections through the yellow tubercles showed, even in the thickness of the visceral layer, a small oblong caseous mass, permeated by the remains of tracts of fibrous tissue in process of destruction. No giant-cells were seen in it. Around this caseous centre was a layer of embryonal cells, most marked in the deep layer of the serous membrane. Over the nodule extended the false membrane already described. The subjacent muscular fibres of the heart were fattily degenerated.

From the comparison of a considerable number of cases of tuberculous pericarditis, Vaillard concludes that it is much less common to meet with effusion than with the dry form, the latter having been met with twenty-seven times out of thirty-seven cases; in only ten was there effusion, of a citrine yellow or sanguinolent aspect. In all the cases of dry pericarditis, with one exception, there was complete adhesion of the two layers of the pericardium. Hence it would seem that adhesion is the habitual termination of this variety. The surfaces are covered by false membranes, in which the tubercles are scattered, as well as in the serous membrane proper. Tubercular granulations may, however, develop in the proper connective tissue of the myocardium, and Fauvel has even traced them through the whole thickness of the wall of the heart up to the endocardium. In the less frequent cases in which there is effusion, this is usually abundant, and may vary from 700 to 1600 grammes (Proust), and even 2800 grammes (Richard). This large effusion is so characteristic of the variety that, given a case of chronic pericarditis, the tubercular nature of the inflammation may be suspected from this characteristic. The layers of the pericardium present changes similar to those met with in the dry form, but the false membranes may undergo degeneration and ulceration, so that ulcers form similar in appearance to the specific ulcers of the intestine. The question has been discussed whether the formation of tubercles is primary and the inflammation secondary, or whether the opposite is the order of events. Cruveilhier, Empis, and Niemeyer have expressed doubts as to the occurrence of tubercles in uninflamed pericardium; and, according to them, the formation only occurs in the depth of the newly formed false membranes. The facts of the question have often been difficult to ascertain, in consequence of the close adhesion of the false membrane and serous layer, so that it is not always easy to say where one ends and the other begins. But many cases have been observed in which tubercles were seated in the thickness of the serous membrane without any trace of inflammation, as in a case in which, the patient having died from acute tuberculosis, miliary granulations were found on the parietal layer, and three similar nodules on the surface of the visceral layer. This renders it probable that, in some cases at least, the formation of tubercles is primary and the inflammation secondary. But it does not follow that this is the invariable order of events; a simple pericarditis may be the occasion of the growth of tubercles in the inflammatory products.

The dry adhesive form of pericarditis is often overlooked during life. Its course is latent, and pericarditis not being expected in the course of phthisis, it is often discovered only at the autopsy. Any dyspnœa which it causes is obscured in the greater dyspnœa due to the condition of the lungs, and when adhesions form friction disappears. The occurrence of effusion renders the symptoms more obtrusive, so that this form is usually recognised during life. If there are no lung symptoms it may be difficult even to suspect the nature of the pericarditis, but a correct diagnosis is, in these cases, of great importance, since the pericarditis is occasionally the first local manifestation of tuberculosis, as in cases which have been recorded by Virchow, Proust, and Richard.

HABITUAL DRUNKARDS.

THE Lord Mayor has placed his influence and the Mansion House at the disposal of those who try to work the Habitual Drunkards Act of 1879, which, as our readers know, is a permissive Act. It sanctions the detention of those drunkards who are willing to place themselves under the restraint of Retreats. The special object of the late public meeting at the Mansion House was to inaugurate on a popular basis and a self-supporting principle a model licensing home for the cure of habitual drunkards. Dr. Cameron divided habitual drunkards into three classes: first, those willing to go into Retreats, which, in America, he says, is the case with 90 per cent. of the habitual drunkards; those whom it is most desirable to put into such cases but who are unwilling to go, and, thirdly, criminal drunkards. It is thought that if a model home were established it might give rise to similar institutions in other parts of the country, and that it would, at any rate, constitute an experiment that would be valuable and interesting in view of the temporary character of the present Act, which is to expire at the end of ten years. We should be very much surprised to see it proved that English habitual drunkards were amenable to reason in the proportion of ninety per cent., as in America. Besides, as Dr. Cameron pointed out, the time, ten years, is far too short to induce persons to expend capital in such an adventure. We confess to having no respect for such legislation. It is in the highest degree discreditable, and we are not sure but that the best way of getting legislation worthy of the name, and proportionate to the gravity of the subject, is to ignore the Act of 1879 altogether.

GALLANT CONDUCT OF SURGEON E. A. H. ROE.

THE annals of the Army Medical Department teem with incidents illustrative of the valour, coolness, intrepidity, and self-sacrifice shown by the members of this branch of our profession under circumstances of emergency and danger—acts the more heroic because for the most part they were performed in cold blood, and not under the stimulus which animates those engaged in actual combat with the enemy. Among the many brave deeds we have recorded, the gallant conduct of Surgeon E. A. H. Roe at the battle of Maiwand deserves prominent mention, the more so since the military authorities, who ought to have brought this act of valour forward for public recognition, have, as is so often the case when medical officers are concerned, been silent on the subject. The facts are briefly as follows:—At the battle of Maiwand, just at the time the troops broke and the retreat began, and when shot and shell were falling into the field hospital tent, Surgeon Roe, who was attending a British soldier whose leg had been shattered by a shell, on looking up from his work found that he was alone with his charge, at the same time he saw the Afghans were in the midst of our men, and were masters of the field. With true heroism, he determined to save the wounded man if possible, and, lifting him in his arms, he carried him to the open. Some camels and baggage animals were close by, and for these Dr. Roe made, hoping to place the man on a spare camel. The Afghan cavalry were, however, too close, and were quickly in the midst of the animals, cutting down the drivers and looting the baggage. Dr. Roe dragged the soldier along, and by keeping in the thick of the press saved himself from the Afghans, who were too busy looting to follow in pursuit. Eventually they came upon the chaplain, whose name unfortunately is not given, and with his aid the wounded man was carried still further away from the enemy. The man died in their arms, and they were forced to leave his body in order to provide for their own safety. Dr. Roe subsequently had the good fortune to overtake the brigade, then in full retreat. Should not some official recognition of the gallant deed be made? It is but little encouragement for good men to enter the Army Medical Department when such services as those described above are allowed to pass not only without reward, but without official notice.

THE CASE OF ARTHUR WATSON.

ARTHUR WATSON, who was lately tried at the Liverpool Assizes before Mr. Justice Mathew, is a telegraph clerk, aged twenty-seven, and on April 29th, 1881, he killed his infant child aged thirteen months. Watson and his wife lived apart, in consequence, it is said, of his intemperate habits. On March 5th, and again on March 22nd, he besought his wife to return to him, but in vain. On April 29th, being the worse for liquor, he visited her again and renewed his entreaties, but with the same result. The child was in the room in its cradle, and, besides the wife, a Mr. and Mrs. Gee (the former a joiner by trade) were present. Watson took the child in his arms and nursed it, but it cried, and Mrs. Gee took it from him. Shortly afterwards he rose from his seat, took a chisel which was lying on the table, and with it he killed the child as it lay in the cradle. The prisoner made no effort to escape, and when arrested said, "I really don't know what I am doing." On searching him a letter addressed to his wife was found in his pocket, the wording of which implied that he was meditating suicide The defence was that the prisoner was insane. Dr. Barron Smith stated that the prisoner was admitted to the Manchester Infirmary in 1876 for an injury to the left side of the skull. Dr. Winterbottom stated that about a fortnight before the occurrence he had attended Watson for right hemiplegia. It was admitted by all the medical witnesses on both sides that the right pupil was larger than the left. Dr. Mann testified to the fact of the right hemiplegia as far back as May, 1879. Dr. Morgan gave similar evidence. The judge put the usual stock questions to the jury. Did the prisoner know the nature of the act he was committing? Did he know right from wrong? The jury returned a verdict of "Guilty" in twenty minutes, and Watson was condemned to death, but has since been respited. This case differs from many others of a similar kind in this: that there is not the slightest doubt that Watson has organic disease of the brain. That he doted on his child is certain, and that the act was unpremeditated there is also no doubt. There is, again, no question that after his accident in 1876 he became "an altered man." He fell off mentally and morally, became liable to attacks of excitement, and took to drink. There is further evidence that his grandmother and a maternal aunt were liable to fits. To every properly instructed and unprejudiced man there can be no doubt that Watson's act was the insane outcome of a diseased brain.

THE TREATMENT OF SPLENIC TUMOURS.

THE inutility of internal remedies in advanced cases of splenic leucocythæmia led Kussmaul to try whether the spleen could not be made to shrink up by numerous punctures in different directions. The results are detailed in an inaugural dissertation by his pupil, J. Jäger. A hollow needle, at first a millimetre and afterwards a millimetre and a half in diameter, was thrust into the spleen of a patient aged thirty-eight, suffering from splenic leucocythæmia. The depth of the punctures was eleven centimetres. The hope was entertained that the hæmorrhages into the substance of the spleen would lead to cicatricial contraction at the spot. The punctures caused the patient scarcely any suffering, but unfortunately the result on the spleen was also *nil*. There was a slight improvement in the course of some weeks, but this seemed attributable to the patient's rest. The spleen did not lessen in size, and the proportion of white to red corpuscles remained much as before the treatment—one white to seven or ten red. But an unexpected effect resulted from the deeper punctures—a considerable increase in the quantity of the urine, lasting for about a day, associated with strangury. The latter commenced an hour after the operation, and continued until the following morning. The specific gravity of the urine was lowered, but it was free from albumen and sugar. Senator has informed Kussmaul that he has also observed polyuria to follow puncture of the spleen. The explanation of the phenomenon is obscure. Kussmaul has also tried galvano-puncture of the spleen, but with no better results. After seven minutes' application the spleen was considerably swollen and painful, but subsequently again lessened in size. On the third application, four weeks after the first, the patient for the first time experienced severe pain in the sternum beneath the spot on which the positive pole had been placed; the patient attributed the pain to the electrode. So far, however, the treatment, if it did no good, did little harm. The same statement cannot be said of the next measure employed, which is unfortunately a contribution to toxicology rather than to therapeutics. A gramme of a 10 per cent. solution of recently prepared sclerotic acid was injected into the spleen. Ten minutes later there was a severe rigor; the legs became rigid and intensely painful, the abdomen retracted, the extremities cold, the face cyanotic, the veins of the neck swollen, the breathing quick and purely costal, and the pupils dilated. Consciousness was unimpaired. The tetanoid attack lasted forty minutes. The temperature rose to 104° F. Abundant sweating followed, with vomiting and watery diarrhœa. The patient died a few hours later. The post-mortem showed that, besides the enlargement of the spleen, the medulla of the bones was affected, but there was no disease of the glands. No trace could be found in the spleen of any effect of the punctures, and there were no adhesions of the organ to the abdominal wall. Death was apparently due to the rapid passage of the sclerotic acid into the blood, but Kussmaul is inclined to ascribe it rather to the rapid passage of the water containing the acid into the blood than to the acid itself! This was found by subsequent examination to be free from other toxic ingredients.

Mosler has tried the effect of injections of dilute carbolic acid and of Fowler's solution into a chronic splenic tumour. The result in Kussmaul's case led to careful precautions to avoid an untoward occurrence. Considerable benefit is said to have resulted from the treatment, although previous measures had been ineffectual.

THE PROPOSED UNHEALTHY AND UNSUITABLE SITE FOR ST. PETER'S HOSPITAL.

LAST week we called attention to the inexpediency of the proposal to erect a building to be used as a hospital for "stone" cases in the vicinage of Covent-garden. Since the publication of our remarks, founded on a rumour which reached us casually, we have been furnished with a copy of the prospectus, to which is appended a view of the projected edifice. It is inexplicable to us that the site chosen should have been selected. The noise and offensive emanations from the market render the locality singularly unsuitable for any institution which is to be used as a house of refuge for the sick. What makes the incongruity of the present proposal conspicuously great is the fact that "stone" cases involve operative processes of especial danger, exposing the patient to peculiar risks of blood-poisoning, and requiring a plentiful supply of fresh air with perfect quiet! Is it too late to reconsider the scheme? There must surely be more fitting sites to be procured elsewhere; and if it be a fact that the purchase of this ill-chosen plot of ground has been hastily concluded, it had better be sold than improperly utilised. We waive nothing of our antagonism to special hospitals in making this suggestion in the interests of humanity. It is a misfortune that hospitals for "stone" or for other special classes of maladies exist; but if they must be, in deference to personal whim or public caprice, the profession and the public have, at least, a right to require that they shall be so placed and so conducted as to secure for those who trust their lives to the keeping of their promoters a fair chance of cure. This will be denied the patients of St. Peter's Hospital if it is located among the pestilent emanations of the offal accumulated in the purlieus of Covent-garden, with the accompaniment of sleep-destroying noises by night and the depressing spectacle of a city burial-ground for the outlook of convalescents by day.

ALLEGED MANSLAUGHTER AT CARDIFF.

A LABOURER and his wife, named Beer, were tried a few days ago at the Swansea assizes for neglecting to provide proper food for their infant, supplying food of an improper character, and failing to get it proper medical treatment. It transpired that the child had been taken to Mr. Morgan Williams for vaccination, who recommended the postponement of the operation on account of the child's emaciation, and that medical treatment should be procured. He advised, in the meantime, Parrish's chemical food. The advice of Mr. Williams was neglected, and the child died about two months after. He refused to give a certificate, an inquest followed, and thereafter the charges upon which the prisoners were tried. The judge said that no doubt the food given—biscuits and bread—was improper, but the jury must be satisfied that the mother had been guilty of neglect of so gross a kind that she should be made responsible for it. The prisoners were acquitted. The judge reflected, we think, much too severely on the medical man for not attending to the case at once without an order. If a parish medical officer were bound to attend every needy case he sees without an order he would indeed of all men be the least to be envied. Besides, the obtrusion of his services without an order would lead to their being despised by the poor and repudiated by the guardians. The child lived two months after Mr. Williams's advice, which was long enough to show what ample time there was for application in a formal way to the parish.

SUPERANNUATION OF MEDICAL OFFICERS.

IT is to be hoped that Mr. Dodson spoke more than merely formal words when he promised attention to the arguments of the Medical Officers' Association for making superannuation compulsory. Dr. Rogers's statement that of 122 suitable applications to boards of guardians for superannuation fifty were refused is very serious. The inadequacy of the mere recommendation of the Central Board in favour of particular applications was well shown in the cases of Mr. Terry and Dr. Downes, who had both served forty years in their respective unions and yet failed, though in one case a Local Government Inspector was sent down to urge the application. Those boards which give the worst salaries are the most unwilling to grant superannuation. This question really touches the efficiency of the whole Poor-law service; and, whether viewed in its bearing on the poor or on the medical officers, should be favourably considered by the Local Government Board. It is vain to expect that the best men can be got for the work, or that any man will give his best services to a duty for which he is so ill paid, and in which he may labour till he is incapable of work, or contract serious or fatal illness, and then be left helpless. Some of the best Poor-law medical officers injure their prospects in general practice by faithfully discharging Poor-law work which has never yet been rewarded in a proper way.

MECHANICAL STIMULATION OF THE BRAIN.

DR. BROWN-SÉQUARD recently announced to the Société de Biologie that he has found, in rare cases, a simple puncture or section of the "motor zone" of the brain of the dog, rabbit, or guinea-pig, gives rise to signs of pain, and this when the dura mater has been entirely removed from the region. The sensibility is that of the brain, not of the pia mater, for the surfaces of an incision into the brain substance were found to possess the same sensitiveness. He ascribes it to the congestion induced by the operation, and concludes from it that the congestion may render parts of the brain acutely sensitive, which normally are destitute of sensibility. It has been especially met with when the brain has been exposed for a little time. These observations agree with some made by Dr. Brown-Séquard thirty years ago, showing that the insensitive spinal cord becomes sensitive when it is inflamed. He believes that the movements observed by some experimenters on mechanical stimulation of this part of the brain are simply reflex, and are not due to the excitation of any motor elements.

THE Royal Commission on the Medical Acts held their first meetings on the 20th and 21st inst., at 2, Victoria-street, S.W. There were present on both occasions the Earl of Camperdown, chairman; the Bishop of Peterborough; the Right Hon. W. H. F. Cogan; the Master of the Rolls; the Right Hon. George Sclater-Booth, M.P.; Sir William Jenner; Mr. Simon, C.B.; Dr. McDonnell; Professor Turner; Mr. Bryce, M.P.; and Mr. John White, Secretary.

THE QUEEN has been pleased to order the following appointments to be made:—Deputy Surgeon-General of Hospitals and Fleets Daniel John Duigan, M.D., Deputy Surgeon-General John O'Nial, A.M.D., and Surgeon-Major Samuel Black Roe, M.B., A.M.D., to be Ordinary Members of the Military Division of the Third Class, or Companions of the Most Honourable Order of the Bath; John Forsyth, Esq., C.B., Inspector-General of Hospitals (Retired), Bengal Medical Service, to be a Knight Commander of the Star of India; William Macgregor, Esq., M.D., Chief Medical Officer and Receiver-General, Fiji, to be an Ordinary Member of the Third Class, or Companion of the Most Distinguished Order of St. Michael and St. George.

A CONFERENCE of delegates and collectors of the Hospital Saturday Fund, together with friends and supporters of the Metropolitan Provident Medical Association, met this week at the Holborn Town Hall, to deliberate on a scheme for the promotion of the provident principle in hospital relief, and for the better treatment of the industrial classes in sickness. It was explained that by the plan proposed 1*s.* per month would be charged for membership, the patient paying for medicine.

THE death is announced of Dr. Barnard Davis, in his eightieth year, at Hanley, where he lived all his life. Dr. Davis was joint author with Thurnam of "Crania Britannica," and was, perhaps, the largest private collector of skulls in Europe. His museum recently passed into the possession of the Royal College of Surgeons. He held the degrees of M.D., F.R.S., and F.S.A., and was a member of numerous foreign scientific societies.

MR. GLADSTONE has been made a Fellow of the Royal Society, and this, too, in a somewhat royal style. He was elected and received, not as an ordinary Fellow, but in such a way as is open to the Society in the case of Royal or distinguished persons. No political bias will prevent a feeling of satisfaction at this action on the part of the Royal Society.

IT appears that there is a dearth of medical men in Shetland. Outside of Lerwick there are but six practitioners to a population of more than 37,000. An appeal has been issued for funds to assist in the establishment of dispensaries in various parts of the island, and to pay medical men for periodical attendance at these institutions.

A LIST of seventy-two names of Irish union hospital physicians has been sent us in support of the memorial to the Senate of the Royal University, praying for the recognition of one year's clinical attendance at such hospitals. Many more signatures are expected.

DR. C. B. MOSSE, C.B., Superintending Medical Officer of Jamaica, has been appointed an Official Member of the Legislative Council of that island.

DR. PEACOCK has resigned his position as Physician to the National Provident Institution, Gracechurch-street.

AT a meeting at Woolwich on Wednesday, in connexion with the movement for instructing soldiers' wives in nursing, Lord Chelmsford, Sir Frederick Roberts, and others testified to the usefulness of the scheme. Certificates of competency were presented by Viscountess Strangford to the successful candidates.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham.—Dr. Alfred Hill reports for this borough in 1880 an estimated population of 394,738, and a death-rate of 20·5 per 1000 inhabitants. This death-rate is much lower than the average of the previous decade (24·04), and lower by more than one per 1000 than in any previous year which the medical officer's records embrace, and 3·86 lower than the average death-rate of the previous fifteen years. Dr. Hill attributes this satisfactory reduction of the death-rate of 1880 to the non-occurrence of any serious epidemic of small-pox, scarlet fever, measles, or whooping-cough; the absence of marked distress, on the one hand, or a too flourishing state of trade leading to intemperance or excess, on the other; the cheapness of the necessaries of life; the mild weather at the end of the year; and the sanitary measures taken by the Corporation. The infantile mortality during the year was greater than had occurred in any year since 1875. In that year the mortality was equal to the rate of 19·6 per cent. of the births registered; in 1880 it was 17·8, and was due to an epidemic of diarrhœa, which prevailed with great severity during August and September. "The death-rate of infants," says Dr. Hill, "is always high in Birmingham, and indicates either gross neglect or lamentable ignorance, probably both; but the main cause of the increased fatality in 1880 was the great prevalence of diarrhœa in the summer quarter." It is of interest to note that while the death-rate from diarrhœa was very high in Birmingham during the year, the general death-rate was the lowest on record. On the relation of atmospheric temperature to the prevalence of diarrhœa, Dr. Hill observes: "Whenever the temperature exceeds 59°, the infantile diarrhœa invariably becomes prevalent. This temperature was maintained every week uninterruptedly from the second week in July until the third week in September, or over nine weeks out of the quarter. No doubt high temperature is the general and principal cause of the appearance of the disease, but as neighbouring towns having similar temperatures are affected differently, there must be some other contributory causes or conditions in operation. High temperature, in addition to acting directly on the system, has the effect of setting up putrefaction in food and other organic matters, thus leading to the ingestion and inhalation of hurtful solids, liquids, and gases. Hence with cleanly and pure surroundings ill effects may be avoided, which, under opposite circumstances, would be experienced in great severity. Whether heat be the sole or principal cause of summer diarrhœa, which is especially a disease of infancy and childhood, or not, it is certainly inseparably connected with the cause, as the disease is almost limited to the hot period in every year. The disease is further observed to be more common in towns than in the country, and in large than in small towns. Communities which are characterised by a high birth-rate naturally exhibit a high infantile diarrhœa death-rate owing to the abundance of subjects of attack." Dr. Hill, commenting on the remarkable diminution of the mortality from the continued fevers in the borough, unhesitatingly attributes the decline to the sanitary work done by the Corporation in the form of better drainage, ventilation, privy accommodation, and improved water-supply. But there is obviously much sanitary work still to be done before Birmingham is placed in a health condition such as it appears possible to compass. The privy nuisance is still serious in the borough, the house-drainage is largely imperfect, houses built upon refuse containing much organic matter are numerous and necessarily unhealthy, and animal keeping in and about houses is a serious source of unhealthiness in some localities. It is gratifying to learn, however, both in the interests of the school children and the borough at large, that the School Board and its officers are giving most willing assistance to the sanitary authority in the promotion of their work. Birmingham must look largely to the more developed notions of the rising generation in sanitary matters for the completion of much of the hygienic work it is now engaged upon. The summary of nuisances dealt with in the course of 1880, and which is given by Dr. Hill towards the close of his report, presents an instructive insight into the sanitary requirements of the borough and the difficulties the local authority and its officers have to contend with.

Watford, Urban (Herts).—Dr. Alfred T. Brett reports for 1880, among a population estimated at 10,400, a birth-rate of 31·05 per 1000 inhabitants, and a death-rate of 20·9. He reminds the sanitary authority that the district needs to obtain more land for sewage-irrigation purposes; more ventilators to the public sewers; baths at the public library; to improve the recreation ground; to prevent the pollution of the river Colne; to have better gas-lamps in the market-place; to adopt the constant water-supply system; and to build a home (hospital) for the treatment of infectious cases.

Ulverston, Urban (Lancashire).—Dr. A. Thompson reports for this district in 1880, among a population estimated at 11,000, a birth-rate of 35·09 per 1000 inhabitants, and a death-rate of 16·55, as compared with 19·27 for 1879. The average death-rate for the district during the five years 1880 was 20·65, and for the five years preceding 1864, 26·15. Dr. Thompson notes that the deaths among infants only included one from diarrhœa, a remarkable exemption from the fatal form of this disease, considering its great prevalence in the kingdom, in the summer quarter.

Taunton, Urban and Rural (Somerset).—Dr. Henry J. Alford's report for this combined sanitary district in 1880 is, perhaps, of chiefest interest from the information it gives of the great value to sanitary authorities of the possession of a well-appointed infectious disease hospital in checking the spread of infectious disease when properly used. *Taunton, Urban*, with an estimated population of 16,227, had a birth-rate of 31·0 per 1000 inhabitants and a death-rate of 19·0. Improvements both in the water-supply and sewerage seem to have constituted the more marked sanitary work in the year, investigations in search of a better water-supply having been crowned with success, and the sewerage of the town considerably extended. Still Dr. Alford confesses to having failed in convincing the sanitary authority as to the necessity of efficient ventilation and flushing as parts of a system of sewerage—a curious but not uncommon instance of perversity among local authorities, who will not hesitate to spend large sums in the construction of sewers, but will hesitate to lay out the money requisite to give them their full efficiency, and will economise pennies at the risk of frustrating the results of the expenditure of pounds. Taunton would appear to have instituted a regular system of scavenging, and as a consequence nuisance arising from gigantic ash-pits is gradually disappearing. The infectious disease hospital, lately erected by the combined urban and rural authorities, seems to have been an unqualified good to the district, both as concerns the patients treated in it and the opportunity it has afforded of checking the spread of infectious disease by isolation. But Dr. Alford longs for the compulsory notification of infectious diseases, without which he finds that he cannot use the hospital so fully and usefully as he wishes. *Taunton, Rural.*—Dr. Alford reports a birth-rate of 31·4 per 1000 population, and a death-rate of 14·0. The total mortality was forty-one below the average of the seven preceding years, and this is attributed not merely to the improved sanitary condition of the district, "but to a great extent to the existence of the sanitary hospital, by which many severe and dangerous outbreaks of infectious diseases were stopped."

Barnsley, Urban (Yorkshire).—Dr. Michael Thos. Sadler reports for this district in 1880, among a population estimated at 29,230, a death-rate of 23·57 per 1000 persons living. The chief features in the health-history of the year were the large increase in the mortality from zymotic diseases, and particularly the great number of deaths from diarrhœa, especially among infants and young children. Dr. Sadler's observations on fatal epidemic diarrhœa deserve careful consideration. "It seems," he says, "as far as one can judge from the experience of the last twelve years in Barnsley, that hot weather in the early part of the summer, say in June, does not produce an epidemic, but if it goes on into July and August, then we have diarrhœa, and if it is prolonged into September then the epidemic is a severe one. Now, last year we had nine hot days in June and five in July which produced little or no effect, then came twelve in August and seven in September, and a violent epidemic spread all through the town, whilst the hot weather in 1872 came especially in June and July. This almost invariable prevalence of epidemic diarrhœa at the time of the year when the simpler forms of animal and vegetable life are at their greatest activity, as shown by the multiplication of insects, animalculæ, fungi, moulds, &c., its aggravation by those conditions of warmth &c. which are favourable to these lower forms of life, and its discouragement by those that check them, strengthen the belief that epidemic diarrhœa, like many other diseases, has for its cause the admission into the human frame of minute organisms which have the power of rapidly multiplying when placed in favourable conditions; and there cannot be much doubt but that these seeds are to a large extent found in the secretions thrown off during the attack. Water contaminated with these matters has been again and again shown to be one of the most potent agents in spreading epidemics of diarrhœa, and the allied but still more serious disease Asiatic cholera; but it is obvious that the infection must be conveyed by some other means in places where the water-supply, as at Barnsley, is derived from a reservoir placed beyond the reach of such contaminations, nor can there be any doubt but that the air is as capable of conveying the germs of diarrhœa as those of small-pox or scarlet fever. It is a matter of common experience that if one person in a house becomes affected with autumnal diarrhœa many others under the same roof will also take it, and that sometimes so quickly that suspicions of poisoning arise, and there probably may be a special liability to infection of this kind in a town like ours, where waterclosets are the exception and not the rule, and where the excreta are kept stored up often for weeks together in conditions more or less favourable to their diffusion through the air. As a matter of fact, the great majority of the deaths from the epidemic of last autumn were in those parts of the town where the houses are most crowded together, and where more than one family have to make use of the same convenience." Dr. Sadler then proceeds to urge the necessity of strict cleanliness being maintained at the time the annual visitation may be expected, and that it is incumbent upon the sanitary department at this time to prevent large accumulations of filth in the vicinity of houses, and to be more free in their use of disinfectants to ashpits and drains. Barnsley would still seem to retain the open, foul midden-privy which is the source of so much unhealthiness among the communities where it is still found.

Tottenham, Urban (*Middlesex*).—Dr. Watson's report for 1880 shows a death-rate of 16·5 per 1000 persons living among a population estimated at 43,968. The death-rate of 1879 was 17·6, and of 1878 17·3. The rapid increase of houses in this district is indicated by the fact that the sanitary authority approved of plans for no less than 3000 new houses during the year. Assuming that this approval is not merely a form, new Tottenham ought to furnish a different and far more satisfactory health-history than old Tottenham. Here, as in many places elsewhere in the kingdom, the prevalence of fatal diarrhœa during the summer was the most notable pathological event of the year. The beginning of the epidemic seems to have set in at a somewhat later period than it did in London. Dr. Watson remarks on this disease, as observed in Tottenham, "In the first place, with scarcely any exception, we must remark that the deaths were all amongst the lower classes, whose dwellings as a rule are damp and unhealthy, and whose habits are dirty and thriftless. Add to this the most deplorable ignorance of the proper manner of feeding children and in nursing them when ill, and we can account for the greater number of cases; but why these deaths occurred when they did, and under the rather peculiar atmospheric conditions then prevailing, I cannot attempt to say." The sanitary authority, we learn, have *at length* decided upon a plan of effectually ventilating and flushing the sewers of the district. The complaint of inefficient ventilation is of old standing against the Local Board, and we are glad to learn that it is about to be removed, for it is not without good reason that the want of ventilation of the sewers is said to have had much to do with the prevalence of diarrhœa, enteric fever, and diphtheria which have from time to time disturbed the minds of residents of Tottenham and of outsiders also.

Whitby, Urban (*Yorkshire*).—Mr. Taylerson reports for the March quarter of the present year, among a population estimated at 14,000, a birth-rate of 32 per 1000 persons living, and a death-rate of 20. Generally the district was remarkably free from fevers and infectious diseases throughout the quarter.

THE SMALL-POX AND ITS LESSONS.

This subject was discussed at the last meeting for the season of the Islington Medical Society on Tuesday last. The chairman, Dr. Glover, remarked on the fact that the most preventable of all diseases was creating such extensive scare and mortality, and on the discreditable appearance of all sanitary and public authorities. It was agreed that there never had been such a demand for vaccination, and that this operation was likely to come into proper reputation only through public experience of the consequences of neglecting it. Mr. Dukes noticed the fact that Germans are vaccinated in eight or ten places, and that they show great resistance to either revaccination or small-pox. Mr. Blackman, public vaccinator in the East-end of London, attributed the greater dimensions of small-pox epidemics to the practice of vaccinating in fewer places than used to be the practice. One member thought that there was too much carelessness in the practice of revaccination, the operation being of no value unless followed by its proper phenomena of irritation, vesiculation, &c. It is undoubtedly true that if it is attempted to vaccinate a large number of persons with a small amount of lymph a large proportion of them will show no result, and yet are apt to be left under false impressions of security from the simple fact of the operation having been done. It cannot be too strongly impressed on the public that they are saved from small-pox, not by being revaccinated, but by being successfully and thoroughly revaccinated.

TILLING THE GROUND FOR FUTURE SMALL-POX.

At a recent meeting, the Lambeth guardians declined to act upon a suggestion of Dr. Stevens, of the Local Government Board, to institute a house-to-house visitation for the discovery of unvaccinated person or persons who had not been revaccinated. The result of such visitation, as carried out in other parts of the metropolis, has been, we understand, most excellent; but the guardians of Lambeth have such tender regard for the feelings of their parishioners that they decline to follow the course recommended lest it should alarm them. This is another illustration of the evil arising from the want of uniformity of action among the boards of guardians in the metropolis, largely frustrating the beneficent operations of the Vaccination Acts. Lambeth, by refusing to carry out to the fullest extent practicable the administration of these Acts, simply stores up in her midst material for the persistency of small-pox, and, in fact, cultivates the ground for further extension of the disease.

At the recent meeting of the Metropolitan Asylums Board, a member, speaking of the difficulties they had to contend with in dealing with the epidemic of small-pox, said, "Every day we read of persons recovering from small-pox being seen in the streets, public houses, and elsewhere, but the Local Government Board seemed unmoved. Why did it not rise to the occasion? But that is precisely the question that the Local Government Board is asking of the Asylums Board, while the metropolis generally is called upon to admire this new version of the old game, 'It's you, Sir,' 'No, it's you, Sir.'"

The Commissioners of the Sewers of the City of London have passed a resolution supporting the Metropolitan Asylums Board in their appeal to the Local Government Board for an amendment of the legislation with regard to that Board, and in view of the removal of the difficulties they have been recently exposed to in carrying out their functions. But here, again, we learn from a statement of Mr. Dodson in the House of Commons that the Central Board is waiting for suggestions from the Asylums Board as to what matters it would like to be amended!

The Camberwell guardians have under consideration a very proper motion for giving pecuniary compensation to one of their relieving officers, small-pox having been introduced into his family, contracted in the pursuit of the duties attaching to the office. It was mentioned in the course of the discussion that in 1877 a relieving officer had had £25 allowed under similar circumstances.

At the meeting of the District Board of Works on the 17th inst., the medical officer of health (Dr. Vinen) was enabled to state that the district was at that time entirely free from small-pox.

The scattering of cases of small-pox from the metropolis has been, we understand, much more marked during the past three weeks. The importation into Warrington and other distant towns is now recorded.

The question of the vestry of Rotherhithe undertaking its own "dusting" has, we are glad to say, been raised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed but a slight further increase last week upon recent low rates. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 4998 births and 3036 deaths were registered last week. The births were 188 and the deaths 221 below the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had been equal to 19·5 and 20·3 in the two preceding weeks, further rose last week to 20·8. The lowest rates in the twenty towns last week were 13·3 in Hull, 14·8 in Brighton, 16·3 in Leeds, and 17·2 both in Portsmouth and Plymouth. The rates in the other towns ranged upwards to 23·8 in Wolverhampton, 24·9 in Manchester, 25·5 in Liverpool, and 25·7 in Oldham. During the first seven weeks of the current quarter the death-rate in the twenty towns averaged 21·2 per 1000, against 23·8, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 410 and 396 in the two previous weeks, rose to 424 last week; these included 104 from small-pox, 94 from whooping-cough, 88 from measles, 57 from scarlet fever, 33 from fever (principally enteric), 28 from diarrhœa, and 20 from diphtheria. The annual death-rate from these principal zymotic diseases averaged 2·9 per 1000 in the twenty towns, and ranged from 0·0 and 0·5 in Norwich and Brighton, to 3·1 in Portsmouth, Bristol, and Oldham, and 3·3 in Liverpool. Measles showed the largest proportional fatality in Bristol and Sheffield, and scarlet fever in Wolverhampton, Sunderland, Oldham, and Bradford. The 20 deaths referred to diphtheria in the twenty towns included 9 in London, 7 in Portsmouth, and 2 in Bristol. Small-pox caused 114 more deaths in London and its outer ring of suburban districts, and 1 in Salford, whereas no fatal case of this disease was recorded in any of the eighteen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 942, 1093, and 1225 at the end of the three preceding weeks, further rose to 1390 on Saturday last; of these 368 were convalescents temporarily accommodated in tents at Darenth. The new cases admitted to these hospitals during last week were 346, against 363 and 379 in the two previous weeks. The Highgate Small-pox Hospital contained 92 patients on Saturday last, and 20 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had steadily declined in the five preceding weeks from 395 to 254, were 256 last week, and were 16 below the corrected average number in the corresponding weeks of the last ten years; they included 140 from bronchitis and 86 from pneumonia. The annual death rate from lung diseases, exclusive of phthisis, was equal to 3·6 per 1000 in London last week; while the rate from the same diseases was 5·8 in Liverpool and 4·1 in Salford.

The causes of 77, or 2·5 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·3 per cent. in London, whereas it averaged 3·7 in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth or Plymouth; whereas the proportions of such deaths were largest in Norwich, Leeds, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half of persons, the annual death-rate last week was equal to 19·9 per 1000, against 21·4 and 20·6 in the two preceding weeks; this rate was 0·9 below that which prevailed in the aggregate of the twenty large English towns. The rates in these eight Scotch towns ranged from 16·0 to 17·8 in Dundee and Aberdeen, to 24·4 and 27·8 in Paisley and Leith. It is noted in the Scotch weekly return that the rate in Paisley is probably over-stated by an under-estimate of its present population. The deaths referred to the principal zymotic diseases in the eight towns, which had been 64 and 82 in the two preceding weeks, declined to 61 last week; they included 16 from whooping-cough, 14 from diarrhœa, 10 from diphtheria, 8 from "fever," 8 from measles, 5 from scarlet fever, and not one from small-pox. The annual death-rate from these zymotic diseases averaged 2·4 per 1000 in the eight towns, and was 0·5 below the average rate from the same diseases in the twenty large English towns. This zymotic rate in the eight Scotch towns ranged from 0·5 and 0·7 in Aberdeen and Dundee, to 3·9 and 5·2 in Perth and Leith. The 16 fatal cases of whooping-cough showed a decline of 8 from the number returned in the previous week, and included 11 in Glasgow and 3 in Edinburgh. The 14 deaths from diarrhœa also showed a decline from the number in the previous week, but were again proportionally more numerous than those referred to this disease in the English towns. Of the 10 deaths attributed to diphtheria 6 were returned in Glasgow, as were all the 8 fatal cases of measles. The 8 deaths referred to "fever" (including typhus, enteric, and simple continued) were 4 fewer than those in the previous week, and included 4 in Leith and 3 in Glasgow. The annual death-rate from this cause was equal to 0·31 per 1000, and again considerably exceeded the average fever death-rate in the twenty English towns. The 5 fatal cases of scarlet fever, of which 3 occurred in Edinburgh, were 7 less than the number in the previous week. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 140 and 111 in the two preceding weeks, further declined to 96 last week, and were equal to an annual rate of 3·8 per 1000, while the rate from the same diseases in London did not exceed 3·2.

HEALTH OF DUBLIN.

The rate of mortality showed a considerable decline in Dublin last week. The annual death-rate in the city, which had been equal to 27·5 and 29·9 per 1000 in the two preceding weeks, declined to 25·2 last week; this rate was lower than that recorded in any previous week of the year. During the first seven weeks of the current quarter the death-rate in the city averaged, however, 29·4 per 1000, against 21·5 in London and 20·7 in Edinburgh. The 161 deaths in Dublin last week showed a decline of 30 from the number returned in the previous week, and included 14, or nearly 9 per cent., which were referred to the principal zymotic diseases, against 8 and 14 in the two previous weeks. The 14 deaths from zymotic diseases included 7 from fever (typhus, enteric, or simple), 5 from diarrhœa, 2 from whooping-cough, and not one either from small-pox, measles, scarlet fever, or diphtheria. The annual death-rate from these zymotic diseases was equal to 2·2 per 1000, while the rate from the same causes was 2·9 in London and 1·6 in Edinburgh. The deaths referred to fever in Dublin, which had been 14, 3, and 8 in the three preceding weeks, were 7 last week, and were equal to an annual rate nearly five times as high as the average rate from the same cause in the twenty large English towns. The 5 deaths attributed to diarrhœa showed a considerable increase upon the number returned in recent weeks; while the 2 deaths from whooping-cough were within one of the number in the previous week. The deaths both of infants and of elderly persons were fewer than in any recent week. Four deaths resulted from violence, but only two inquest cases were recorded during the week.

SICKNESS RETURNS IN SALFORD.

Dr. Tatham, the medical officer of health for Salford, has just presented to his local sanitary authority a quarterly return, which in one essential particular should serve as an example for periodical returns intended to supply a health bulletin of the population to which they relate. It appears that the Health Committee of the Town Council recently decided, at the suggestion of the Local Government Board, to procure for the information of the Health Department a weekly return of the cases of sickness treated by the Poor-law medical officers of the union. Dr. Tatham has been enabled, by the courtesy of the medical officers and the governing bodies of the various medical charities, also to obtain returns of the whole of the cases of sickness coming under the notice of the various hospitals and dispensaries of the district. Thus the sickness statistics which are published in the return before us include all the cases occurring in public practice within the borough, whether coming under the notice of the various hospitals or of the parochial authorities. The value of such a return cannot very well be over-estimated, and it may be hoped that what has been effected by the Town

Council and medical officer of health for Salford may encourage the sanitary authorities and the medical officers of health of other large towns to attempt the preparation and publication of similar returns, combining sickness and mortality statistics. Experience will best show how this combined information may be best turned to account, and to this end it will be interesting to note the varying relations of mortality to sickness in different seasons and in different parts of the borough. It may prove desirable to separate the cases of pauper sickness from those occurring in hospital practice. It must, moreover, not be lost sight of that the relation of mortality to pauper sickness will, to a great extent, be governed by the proportions of the population in different parts of the borough in receipt of poor-law relief. In order to facilitate a comparison of the weekly mortality and sickness returns we should be glad to see the deaths from all causes inserted in Table I. of the Return, just above the line for sickness from all causes. In calculating the rates of mortality for his return, Dr. Tatham has used the recently enumerated population number, which, being 18,000 less than the estimate used by the Registrar-General, gives a death-rate more than two per thousand in excess of the rate given in the last official quarterly return. We are glad to learn that Dr. Tatham calls attention to the excess of uncertified causes of death, and to the small percentage of inquests held in Salford, compared with the proportions prevailing in the neighbouring municipality of Manchester. The power of the coroner to obviate the dangerous neglect of human life indicated by a high percentage of uncertified deaths in town districts is beyond all question; and by neglecting to exercise this power coroners and county magistrates incur a grave responsibility.

AMERICAN DEATH-RATE.

We have frequently called attention to the general untrustworthiness of American mortality statistics, arising partly from incomplete registration of deaths, and partly from exaggerated estimates of population. We are glad to find that the full import of these defects is beginning to be recognised in the United States. In a recent number of the *Boston Medical and Surgical Journal* we note a leading article on the "computation of death-rate as illustrated by Baltimore," which should effectually call public attention to the way in which American vital statistics are discredited by what our transatlantic contemporary describes as "the outrageous inflations of estimated population for the purposes of local self-glorification." We not long ago noted the conspicuous case of St. Louis, which claimed a population of 500,000, and used this figure as the basis of its vital statistics, whereas the census enumerators could not count more than 350,522 inhabitants. Philadelphia, in a similar manner, claimed an excess of 53,000, Baltimore 60,000, and Cincinnati 24,000. Even since the census these towns insist that their inflated estimates are more trustworthy than the census numbers. In Baltimore, the wildest bases of estimate are urged in support of the assertion that the population of the city must be 400,000, instead of 332,190, as shown by the State census. The ingenious secretary of the Baltimore Board of Health urges in support of his estimate, and to disprove the census number, that the city has 80,000 registered legal voters, and five inhabitants to a legal voter being a fair and reasonable allowance, the population must be 400,000. Further, that as the census taken by the police for school board purposes gave 86,961 children aged between six and twenty-one years, assuming that this represents one-fifth of the population, it follows that the population must be 434,805. Again, we are told that Wood's City Directory gives, after deducting all firms, companies, and institutions, 84,596 white, and 13,853 coloured, names—and that it being perfectly fair and reasonable to assume four inhabitants to each—it follows that the population of the city must be 393,796. This latter estimate is the one which the Board of Health still persists in using as the basis of its vital statistics, instead of the census number. A rough calculation based upon the number of houses in the city, and upon the assumption that the 80,000 inhabited houses contain on an average five persons, gives by this method a total population of 400,000. There is something amusing in the persistence with which the Board of Health clings to its random estimate, based upon a supposed proportion of names in a directory, in preference to the census number. The secretary to the Board still asserts that the "census of Baltimore, if correctly taken, would give her a population of fully 400,000." It is quite evident that so long as each civic sanitary official is free to estimate the population of his city by such loose methods as those which have found favour in Baltimore the computation of death-rates must remain an utter farce, and only serve further to discredit American vital statistics. Between censuses some form of estimate is indispensable, but there is, at any rate, novelty in the persistent use of such estimates after the declaration of the census numbers, on the ground that these latter are not trustworthy. It is needless to point out that the addition of this 60,000 to the enumerated population of Baltimore entirely destroys the value of the calculated mortality statistics issued by the Health Department.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DR. B. W. RICHARDSON, F.R.S., ON THE MANAGEMENT OF SMALL-POX IN THE METROPOLIS, ETC.

The discussion of Dr. Richardson's suggestions on the management of cases of small-pox and other infectious diseases in the metropolis and large towns, before the Sanitary Institute, was brought to a close on the 18th inst. Dr. Richardson, in reply to the various observations which had been made in the course of the discussion, remarked that all appeared to be agreed upon the propriety of obtaining a complete registration of communicable diseases, the mapping out of the special centres of infection in each parish, and the formation of a definite notion of the actual hospital accommodation the parish would require from time to time, also the desirability that every parish should bear its own burden. Opinion was less uniform upon the question of large or small hospitals for the reception of infectious diseases, but nothing had been said which called upon him to reconsider the opinion he had formed of the greater advantages to be derived from the use of small hospitals, and he reiterated his views on this subject. On his special plan for dealing with small-pox cases in hospital, he said:—"Objection is taken to my plan of dealing with those small-pox patients in a district who have no home. The plan is said not to be practical, but it exists in practice already. In private houses we send the small-pox sufferer to the top room of the house; we isolate there, and we treat, notwithstanding the existing faulty arrangements, with success. London at this moment is, in fact, a badly managed upper floor hospital, even now, to a considerable extent. I say carry that plan out on a better scale for the poor who suffer by making a sufficient number of small efficient upper floors. There are thirty-nine vestries concerned; for argument's sake, divide equally. Let each vestry, on its boundaries, set up four hospitals of light construction on the upper floors of existing or of new buildings. Let each hospital take in twelve patients. There then would be accommodation for 1872; and if by a mutual accommodation between parishes one would receive for another in emergency, the whole question of dealing with the out-of-home infectious cases in London would be solved. Such small hospitals would not even be noticed after a time, and their management would be so easy, that they could not be sources of danger if any efficiency deserving the name of efficiency were bestowed upon them." Dr. Richardson, in support of the practicability of his suggestions, illustrated his observations by exhibiting a model of a small iron hospital arranged for destroying organic emanations by fire. Dr. Richardson's comparison of the upper-floor hospital he would erect with the treatment of infectious diseases on the upper floors of private houses is, we fear, more figurative than practical. The purchase or erection of buildings as sites for hospitals has not, we think, received from him such consideration from an economic point of view as would have seemed advisable before its proposition as a practical measure was formulated. Moreover, we should like to have heard something more definite how the parochial principle of dealing with small-pox and other infectious diseases was to be brought about. There appear to us both legal and economic objections standing in the way of Dr. Richardson's proposals, for the avoidance of which we see no present means. Further, so far as metropolitan parishes are concerned, the parishioners of Fulham, Kensington, and Paddington, at least, repudiate as earnestly parochial hospitals as hospitals for combined parishes.

WOOLSORTERS' DISEASE.

The local papers continue to report cases of woolsorters' disease from Bradford and its vicinity, and that in spite of precautions being taken to render the wool innocuous. One of these, an alpaca sorter, forty-six years of age, died after a few days' illness, and bacilli were found in the blood during life. Two other alpaca sorters, seriously ill about the same time recovered; but in one of these the blood was found to contain bacilli. A second and third fatal case came from another factory, one being a carder of Cape mohair, who died after forty-one hours' illness, and the other a wool-washer of Van mohair, who was seventy-two years of age, and had enjoyed perfect health until the time of his fatal seizure, which was followed by death in about forty-seven hours. In neither of these latter cases, it will be seen, was the deceased a woolsorter, and in the one who had to do with Van mohair, it is said that the material before reaching his department had been washed at a temperature of 130°, dried, sorted, washed again, prepared and combed. The details of the cases at present to hand are not full enough to enable us to say with certainty that they were cases of anthrax; but the rapidity with which death followed, with all the symptoms of blood-poisoning, hardly leave room for doubt; and the discovery of the bacillus in the first case places that case undoubtedly in the category.

TYPHOID FEVER IN RUSSIA.

The mortality statistics for St. Petersburg, published from time to time in the Registrar-General's weekly returns, afford the strongest evidence of the insanitary condition of that city in the remarkable fatality of typhus and enteric fever which prevails. There is, moreover, every reason to believe that even this excessive death-rate from fever is exceeded in many of the other large Russian towns. Moscow, the ancient capital of Russia, from reports furnished by the United States Consul to the National Board of Health at Washington, appears, at any rate, to be suffering from a greater fever fatality than St. Petersburg. The population of Moscow is stated to be 601,969, among which 2214 deaths were recorded during January last; of these 265 were attributed to typhoid fever, 25 to small-pox, 26 to scarlet fever, and 90 to other contagious diseases. The deaths from typhoid fever were equal to an annual rate exceeding 5 per 1000 of the population; this exceeds by more than twenty times the average death-rate from the same cause in the twenty large English towns during the first quarter of this year. It is also important to note that no less than 215 deaths are also referred to diarrhœal diseases; as intense frost prevailed during the greater part of January, it is probable that a large proportion of this fatal diarrhœa was of typhoid origin. The annual death-rate from all causes during the month is reported to have been equal to 43·3 per 1000.

We learn that petechial typhus is prevalent in Kars and in the districts of Persia recently overrun by the Kurds. The report, moreover, is contradicted that the plague on the Lower Euphrates has extended to Divanieh; and news from Bagdad reports that the disease is now confined to Nedjef, and that it still prevails seriously there.

The lecture delivered before the Victoria Institution on the 16th inst. by Sir Joseph Fayrer, M.D., F.R.S., on "Rainfall and Climate in India," has been printed and issued as a pamphlet.

The water-supply of Aberdeen, especially of the northern parts of the city, having been found unsatisfactory, the city surveyor has formulated a scheme to remedy the defect, at a cost of some £11,000.

THE SERVICES.

War Office.—The Secretary of State for War has appointed John Dunbar Baskerville, Esq., L.R.C.S. Irel., L.R.C.P. Edin., and L.A.C. Lond., to be Assistant Visiting Surgeon for Chatham, under the Contagious Diseases Acts, 1866 to 1869, vice J. B. Jardine, M.D., appointed Visiting Surgeon.

Surgeon-Majors A. F. Bradshaw, F. W. L. Hodder, and G. G. Gibson are on passage home from India in H.M.'s troopship *Jumna*.

Surgeon-Majors H. C. Guinness, M. Cogan, and Surgeon P. H. Johnstone are on duty with troops proceeding from Bombay to Portsmouth in H.M.'s troopship *Serapis*.

Surgeon-Major R. Tate and Surgeon J. A. M'Cracken have been granted leave of absence from India for six months, on private affairs.

Surgeon-Major C. Innes, A.M.D., has been granted leave of absence from Bengal for six months, on urgent private affairs.

PHARMACOLOGY AND THERAPEUTICS.

CANTHARIDINE.

An interesting observation on the effect of cantharidine was recently published by M. Cornil. If this substance is given to a rabbit, either by the mouth, or through the skin, as by the application of a blister, the symptoms of poisoning are produced, cystitis, nephritis, and inflammatory lesions in the liver and the lung. Twenty minutes after the ingestion of the cantharidine, the following lesions were found in the glomeruli of the kidney. A large number of white corpuscles lay between the capsule and the tuft of blood-vessels composing the glomerulus. The uriniferous tubes were filled by a granular exudation obliterating their cavity. An hour after the dose there was an abundant proliferation of cells, round or angular from compression, the signs of a true catarrh of the tubules. In the bladder the changes were of the same character, but superficial, apparently in consequence of the irritation being due only to the character of the urine. In the lung, the minute bronchi were filled with pale corpuscles or pus-cells, and a similar change was found in all the bronchial tubes, and even in the mucous membrane of the trachea and larynx. Similar lesions were found when a blister had been for some time in contact with the skin.

ASPIDOSPERMINE.

The physiological and therapeutical action of aspidospermine, the alkaloid of quebracho bark, has been investigated by Penzoldt; it consists of white prismatic crystals readily soluble in alcohol and ether, but only slightly soluble in water. The solution has a yellowish colour and an intensely bitter taste. In frogs ten milligrammes caused complete motor paralysis similar to that caused by a cubic centimetre of solution of the bark. The heart's action was reduced in frequency, and the thoracic respiratory movements were at first shallower, and afterwards less frequent. Six centigrammes injected beneath the skin of a small rabbit caused, in eight minutes, distinct motor weakness and dyspnœa. In two others, fifteen minutes after the same dose, dyspnœa came on without obvious narcosis or diminution of sensibility, and death occurred with symptoms of muscular paralysis, accompanied by intermitting spasm. The respiratory curves showed first a slight increase in frequency, which afterwards became greater, with increased depth of inspiration. In dogs also considerable dyspnœa was produced, with increased frequency of pulse. Administering it in ten cases of dyspnœa in doses of from one to eight centigrammes in phthisis and emphysema, no marked effect on the dyspnœa was observed; nor could he trace, in febrile conditions, any distinct influence upon the temperature. On the other hand, a one per cent. solution delayed putrid decomposition of urine, but did not prevent the growth of bacteria and fungi. The effect on forms of dyspnœa was so much less than that of the quebracho bark, that Penzoldt believes this must contain, besides aspidospermine, another active substance. This more active principle has been lately separated by Hesse, who finds that the bark contains even larger quantities of it than of aspidospermine. He has termed it *quebrachine* and assigns to it the formula $C_{21}H_{26}N_2O_3$. It is a strong vegetable base, and in alcoholic solution blues litmus. The sulphate and hydrochlorate are crystalline.

KURCHICINE.

An Indian chemist, Babu Ram Chundra Dutta, has obtained an alkaloid from the bark of Holarrhena antidysenterica, to which he has given this name from a native word for the plant. The bark (Conessi bark) is a well-known Indian remedy for dysentery; and the alkaloid, according to the *Pharmaceutical Journal*, is the same as that which has been twice discovered before—in 1858 by Haines and in 1865 by Stenhouse; each time, however, attracting little attention. There seems to be more probability now that it will be utilised in medicine. It is white, non-crystalline, and very bitter to the taste, readily soluble in alcohol, ether, and dilute acids, less soluble in chloroform and benzol. Crystalline acetate and tartrate have been obtained. The bark yields about three per cent. of the alkaloid, and it is present also in the seed. The dose is two to five grains, and it may be given as a powder, or dissolved in water by means of a little acetic acid. It has been found to be in no way inferior to the cinchona alkaloids as an antiperiodic, and not to produce nausea, vomiting, or headache.

THE INFLUENCE OF PHOSPHORUS ON METABOLISM.

Phosphorus in toxic doses, has been found by Fränkel and Röhmann to cause in fowls a great increase of metabolism. The phosphorus was given in bread pills, by the stomach, fasting, and the excrements were carefully collected and analysed. In each of three investigations a considerable increase in the amount of material excreted was found to occur. The amount of nitrogen was nearly trebled, and that of uric acid was doubled, and the uric acid was increased not only absolutely, but also in proportion to the other constituents. In this relative increase of uric acid the experimenters see an analogy to the formation of leucin and tyrosin in the mammalia. The phosphorus caused also an extreme diminution in the number of red corpuscles in the blood, which fell, in one case, to a sixth of the original number.

MORPHIA.

Landesberg, employing the method of Uslar and Erdmann for the discovery of morphia in the urine, could not find a trace of it in the urine of dogs which had been poisoned with the hydrochlorate or the sulphate of morphia. The brain, the medulla oblongata, the blood, and the liver were also analysed and found free from morphia, in the case of large dogs. Only in a small terrier was a trace of morphia found in the urine the day after the injection of twelve grains of morphia into the jugular vein. In the blood of the same animal, three hours after the injection, no morphia could be found. The conclusion which this investigator draws from his experiments is that when morphia is injected subcutaneously, it passes gradually into the blood current, and, by the alkalinity of the blood, it is quickly changed and decomposed, being secreted through the kidneys chiefly as decomposition products. These conclusions are, however, difficult to reconcile with the prolonged influence of morphia on the nervous system, unless this effect is really exerted by some of the decomposition-products.

A NEW SOURCE OF THYMOL.

Thymol is found to be contained in considerable quantities in the ajowan seeds (Ptychotis ajowan), which have long been used in India as a remedy for colic, atonic dyspepsia, and diarrhœa. It is suggested by Mr. Christy that should the demand for thymol increase, a supply might readily be obtained by the cultivation of this plant.

NEW ANTISEPTICS.

Styrone, or cinnyl alcohol, has been tried with success in America, and is said to have an antiseptic power greater even than thymol. It is obtained from the styracine of balsam of Peru, or liquid storax, by treating it with it an alkali which separates the cinnamic acid from the cinnyl alcohol. According to the *Pharmaceutical Journal* it is in the form of silky crystals, has a sweet taste, and an odour of hyacinths. It is soluble in twelve parts of water, in alcohol, and in ether. A saturated aqueous solution was found to be a perfect deodoriser of a foul ulcerated surface, and to cause no irritation. This explains, to a certain extent, the healing properties long attributed to tincture of benzoin, of which liquid storax is an ingredient.

Another antiseptic is the oil of eucalyptus. To it Mr. Lister has lately called attention. It is said to cause no irritation, even to very sensitive skins. Three parts of the oil may be dissolved in fifteen parts of alcohol, and then 150 parts of water added. Gauze wetted with the solution is to be covered with gutta-percha tissue and kept in place in the ordinary manner by gauze bandages.

The use of a combination of salicylic acid and camphor as a surgical dressing has been suggested by Dr. Lajoux, with the idea that the salicylic acid would act on the albumenoid ferments and the camphor on the organisms of wounds. The compound has been employed by Dr. Henral, it is said, with satisfactory results. It was far more efficacious than any other application in a case of ulcerated lupus in a syphilitic patient, the sores immediately assuming a more healthy aspect and soon healing. A phagedænic ulcer of the fourchette, which had lasted for six months, was healed in a fortnight.

PICRIC ACID.

Subcutaneous injections of carbolic acid have been extensively used in Germany for the local treatment of erysipelas. The affected region is enclosed by a series of injections of a one per cent. solution, and these are repeated daily, morning and evening, until the fever has subsided. They appear to produce no local irritation. M. Flaminio Tassi has lately recommended picric acid for the same purpose. He was led to employ it by the consideration that this acid, penetrating into the deeper layers of the skin, exercises an astringent action on the vessels, and also acts as an antiseptic. The astringent action may be expected to lessen the migration of leucocytes, which, as Wolmann and Steudner have shown, attends the erysipelatous dermatitis. In four cases in which he has employed this method of treatment the extension of the inflammation was effectually arrested, while the patients have complained of no inconvenience. In addition, compresses wetted with a saturated solution of this acid were applied over the inflamed area.

Chéron has pointed out that picric acid is a very powerful antiseptic. It has been employed at Saint Lazare for the disinfection of latrines, and it was found that the fæcal odour was readily removed by it. It also prevents the putrefaction of urine, and is said to be a useful application to wounds. The potash salt has been given as a febrifuge with good effect by Braconnot. Dr. Wainwright of New Jersey has treated malarial fevers with success by picrate of ammonium. He has given it as a pill in doses of a grain or a grain and a half, increasing it to two grains. Few cases, it is said, had to be treated longer than a week, and if given at the commencement of the disease, it was quickly cut short. It does not affect the ears as does quinine. The urine is rendered yellow, and the skin and conjunctiva are similarly stained, but the colour disappears at the end of a week.

RHINACANTHIN, A NEW REMEDY FOR RINGWORM.

Dr. Liborius having observed in China that the tincture of an unknown fibrous root was used successfully as a remedy for ringworm, obtained some of the plant, which turned out to be the Rhinacanthus communis, the plant of which the leaves, bruised and mixed with lime-juice, are used in India as an application for the same complaint. According to the *Pharm. Zeit. f. Russland* and the *Pharmaceutical Journal*, Dr. Liborius has since obtained from the root a quinone-like body, supposed to be the active constituent. It resembles chrysophanic acid in being antiseptic and antiparasitic. He proposes to call it rhinacanthin, and represents it by the formula $C_{14}H_{18}O_4$. It occurs only in intercellular spaces within the bark, which contain an intensely red substance, supposed to be a compound of rhinacanthin with an alkali. It forms with bases beautiful red compounds, easily decomposed by certain neutral solvents, such as petroleum spirit, which dissolve the rhinacanthin and assume a yellow colour.

OIL OF ANDA ACU.

This oil, obtained from the Anda Brasiliensis, has been recommended as an aperient in place of castor oil. A smaller dose is said to be required, and its action is free from intestinal irritation. The seed is ten times as large as that of the castor oil plant. It is necessary to remove the embryo and episperm before the oil is expressed, since these contain a principle which produces colic.

THE THERAPEUTIC ACTION OF OXYGEN.

M. G. Hayem has communicated to the Académie des Sciences a fresh series of researches on the influence of inhalations of oxygen. When forty to ninety litres a day are inhaled in two doses, mixed with an indefinite quantity of ordinary air, the functions of nutrition are energetically stimulated, the appetite is quickened, the temperature is slightly raised, the circulation accelerated, and the weight of the body is increased. The formation of hæmatoblasts and of red corpuscles is greatly increased, and the amount of hæmoglobin contained in the latter is augmented 5 or 10 per cent. These effects are, however, transient; when the inhalation is suspended the blood resumes its previous com position. In chlorosis this influence is very useful. Appetite returns, vomiting ceases, and the weight of the body is increased, and the amount of urea excreted is also larger. The number of red corpuscles becomes greater, but their value is unchanged, and may even be lessened. At the end of two or three months, in spite of the improvement in the general state, the condition of the blood presents little alteration, and the beneficial results are soon lost when the treatment is discontinued. Neverthelsss, the inhalations of oxygen are regarded as a useful adjunct to treatment. Vomiting, from whatever cause, is influenced in a remarkable manner, being usually suspended by one or two inhalations. This result has been obtained in dyspepsia, in pregnancy, and anæmia. In cancer of the stomach and in phthisis the vomiting was merely rendered less frequent.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Friday, May 20th, Dr. Cameron gave notice that on that day four weeks he would call attention to the lack of capacity and resource shown by the Local Government Board in dealing with the small-pox epidemic at present raging in London and move a resolution.

Importation of Drugs into Japan.

Mr. Alderman Fowler asked the Under-Secretary for Foreign Affairs whether Her Majesty's Government had made any communication to the Government of Japan in regard to the introduction of drugs and chemicals into that country.—Sir C. Dilke said Her Majesty's Chargé d'Affaires in Japan was instructed in July last to take such steps as might be necessary for the protection of British importers of drugs in case there should be proper grounds for the intervention of Her Majesty's Government. No complaint had been received since that date. Two complaints had been received previously.

Compulsory Vaccination.

On Monday, Mr. H. Lee asked the Secretary of State for the Home Department if the Lord Chancellor, after submitting to the Town Council of the borough of Southampton the name of James Seward Pearce, the sheriff of the town and county of Southampton, now declined to add his name to the roll of borough magistrates; and whether the ground of objection was the opinion Mr. Pearce held in relation to compulsory vaccination, and the fact of his having been fined for non-compliance with an order under the Act; and whether the Government proposed to make this a disqualification in the case of all justices of the peace who held similar views.—Sir W. Harcourt said he had communicated with the Lord Chancellor on the subject, and he stated that the ground of his objection to that gentleman did not relate to any opinions entertained by Mr. Pearce, but to the fact that he had been twice convicted before the borough magistrates, the last time as recently as 1879, for offences against the Vaccination Act, and fined. The Lord Chancellor was not informed of those facts when he mentioned that Mr. Pearce had been recommended to him as a fit and proper person for a borough magistrate. They were afterwards brought to his notice by a memorial, and the Lord Chancellor felt obliged to concur in the opinion that a gentleman who had not recognised the duty of obeying the law which magistrates were bound to administer was not likely to be a good example to those brought before him, and was not himself, therefore, suitable to be appointed as a magistrate.

The Small-pox Epidemic.

Mr. Dodson, in reply to Mr. W. H. Smith, said he had received a representation from the managers of the Metropolitan Asylums District as to the alleged necessity for legislation to define and enlarge the powers of the managers and local authorities. Independently of, and prior to this, the subject had much engaged the attention of the Local Government Board, who were now in communication with the managers for the purpose of ascertaining the nature of the amendments of the law which appeared to them to be required. When the Board had received their reply they would be in a better position to determine what steps it might be expedient to take, but at present it would be premature to express an opinion.

Petitions were presented as follows:—From the King and Queen's College of Physicians in Ireland, for alteration of the Coroners (Ireland) Bill; from Charles Hatchell, for inquiry into the East India Medical Department; and from St. Giles's, Camberwell, against a loan to the Metropolitan Asylums District to carry on litigation in the Hampstead Hospital case. The Registrar General's annual report of births, marriages, and deaths in England (abstracts of 1879) was presented, as also was a return of deaths from small-pox in the metropolitan district from Jan. 1st to April 30th, 1881.

On Wednesday, petitions against the Rivers Conservancy and Floods Prevention Bills were presented from Leicester and other places, and for alteration of the Bill from the Liverpool Land and House Owners' Association. Mr. Dillwyn's Lunacy Law Amendment Bill was read a second time, after a debate in which Mr. Courtney, Dr. Cameron, Sir Henry Holland, Sir R. Cross, and Sir W. Harcourt took part.

Variolous Vaccination.

Mr. Hopwood gave notice on the following questions for Monday next:—To ask the President of the Local Government Board, whether it is the fact that the matron and one or more nurses at the hospital at Halifax have recently taken small-pox a few days after revaccination; whether there is any reason to believe the vaccination was of variolous matter; and, whether it is the fact that there is in use in the country a large quantity of vaccine which is in fact variolous matter, or small-pox communicated from the human subject to cattle, and from them extracted and used in inoculation under the Vaccination Acts.

Vaccine Lymph.

On Thursday, Mr P. A. Taylor asked the President of the Local Government Board whether his attention had been directed to the fact that an absolute diversity of opinion existed at this moment amongst our highest medical authorities in regard to certain lymph still used, Sir Thomas Watson declaring that the lymph which had been largely used at Brighton and elsewhere for the last forty years was variolous, and such as "must have spread about a vast amount of mitigated small-pox;" while Dr. Carpenter asserts that "no vaccinator could be charged with propagating small-pox, even though it were put beyond doubt that his vaccine lymph had been remotely derived from a small-pox pustule;" and whether he did not think it would be safer to discontinue the practice of vaccination altogether until at least our highest medical authorities could agree upon the not unimportant point as to whether the lymph employed was a protection against small-pox, or whether it might not be simply an agent for the diffusion of small-pox.—Mr. Dodson said he believed Sir T. Watson did use the words quoted in a letter to a medical journal on January 17th, 1880, but in a subsequent letter he said, referring to an important paper by Mr. Ceely, of which he had no previous knowledge, "A careful study of it convinced me that I was in error in respect to the statement with regard to small-pox and cow-pox, I am in duty bound to acknowledge this and to apologise for it." He (Mr. Dodson) could not admit that there was any substantial difference amongst the highest medical authorities on the point as to whether the lymph employed was a protection against small-pox, or whether it might not simply be an agent for its diffusion. As far as he was aware, the great bulk of the authorities were of opinion that to those employed in vaccination it was a protection against small-pox, and not a means of its diffusion. If all measures for preventing or curing diseases in regard to which some difference of opinion amongst doctors might be found were to be postponed until they all agreed, not only vaccination, but all medical treatment, would have to be suspended for probably an indefinite number of centuries.—Mr. Dawson asked if there was any provision in London in the case of an epidemic, such as was now raging, to supply vaccine from animals as was the case in foreign countries.—Mr. Dodson said that notice must be given of the question.

Contagious Diseases Acts.

Mr. Hopwood asked the Secretary of State for the Home Department whether it was the fact that one or more surgeons employed in the compulsory examination of prostitutes under the Contagious Diseases Acts had been made justices of the peace, in order that they might carry out the Acts in a twofold capacity, administering and executing the law; whether he would state by what Minister such gentlemen were recommended to her Majesty for appointment; whether he approved of such a confusion of duties; and whether the individuals in question should not be called upon to make their choice once for all to act either as magistrates or surgeons.—Sir W. Harcourt said he had made inquiries and could not discover that any such appointment had been made.—Mr. Hopwood asked whether a Mr. Parsons had not been appointed and was now acting.—Sir W. Harcourt asked when and by whom that gentleman was appointed.—Mr. Hopwood said he was appointed by the ex-Lord Chancellor.

Contagious Disease in Dublin.

Mr. Cavendish Bentinck asked the Secretary of State for War whether the general commanding her Majesty's forces in Ireland had not recently forwarded a report showing the lamentable state of the garrison in Dublin in connexion with contagious disease, and whether he would have any objection to lay the report on the table of the House? Mr. Childers: "Yes, sir, there is such a report; and although I deprecate its appearing in print, I have no objection to lay it on the table."

The Case of Captain Chatterton.

In answer to a question by Mr. Grantham with reference to this case, the gist of which appeared in our "notes" last week, Lord Hartington said he only noticed the question in the paper this morning, and he must confess he had not had time to investigate fully the various matters it contained. He did not think the military department of India had had time to make their examination. The General Brigade and Divisional Orders to which the hon. gentleman referred had never been received in the India Office, for it was not the practice to send them home from India. He would, however, have the question further examined into with the view of seeing whether it contained anything which did require further reference and inquiry in India, but he could not hold out any hope to the hon. member, considering the number of times this case had been brought before different Secretaries of State, that it would be possible to take further action.

Correspondence.

"Audi alteram partem."

VACCINATION AND REVACCINATION.

To the Editor of THE LANCET.

SIR,—I think that in the present state of the vaccination discussion, the following facts may be of interest to your readers.

It was in the year 1836, or thereabouts, that my former master, Mr. J. B. Estlin, of Bristol (who had always taken a lively interest in the spread of vaccination, and was impressed with the inferior potency of the "vaccine" then in use), hearing of a fresh outbreak of cow-pox at Berkeley went down thither and brought with him supplies of fresh lymph from three sources. 1. The teats and udder of the cow. 2. The hand of one of the milkers infected from No. 1. 3. The arm of a child vaccinated from No. 2. Mr. Estlin and his friends (myself among the number) having got together a number of children, vaccinated them with each of these lymphs, and I very distinctly remember the following to have been the general results. 1. Of those vaccinated direct from the cow only a small proportion "took" the vaccine. 2. Of those vaccinated from the milker a larger proportion "took." 3. Of those vaccinated from the child's arm nearly as many "took" as in an ordinary vaccination of the same number. Again, in those vaccinated either direct from the cow or from the milker the disease produced was much more severe than I had ever seen it. The vesicles had pus (or what looked like it) mingled with the lymph; the areola was very large and angry-looking; and the febrile disturbance considerable. In several instances there was inflammation of the lymphatics, and in one case axillary abscess. After a few "removes," however, the virus seemed to have been toned down, vaccination with this new lymph producing what our elders pronounced to be the original Jennerian cow-pock, which they considered to have greatly deteriorated.

Now, putting aside altogether the question of the fundamental identity of cow-pox and small-pox, I think these facts of interest as clearly showing that a modification takes place in the cow-pox virus by its "cultivation" in the human subject, and that this modification, very marked in its early stages, may tend to render it *too* mild, and thus impair its protective potency. Hence I should suggest to country practitioners to keep their ears open as to any recurrence of genuine cow-pox among cows, and to have recourse to any fresh "stock" that may come in their way, without allowing themselves to be baffled by the difficulties attending its first propagation, or alarmed at its unusual results.

An old friend, Mr. G. T. Clark, who, like myself, began life as a medical man, but early quitted practice for other pursuits, and who has been for twenty-two years chairman of the Merthyr Board of Guardians, has communicated to me the following as *his* experience in that large and populous union:—"Since the Compulsory Vaccination Act has been put into force the reports of our vaccine inspectors are returned weekly and read to the Board, and the division of the union has enabled the vaccinators to reach and keep in view the case of every child vaccinated. The result of these arrangements has surpassed our utmost expectations. Cases of small-pox were wont to be frequent. It is now some years since a case has occurred in the union."

I am, Sir, yours truly,

May, 1881. WILLIAM B. CARPENTER.

EXCISION OF THE HIP-JOINT IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—In your last issue, at page 826, is an abstract of the Report of the Committee of the Clinical Society on Excision of the Hip-joint in Childhood, and in reference to an important point connected with the operation, the following remarks are made, "Only the diseased bone should be removed, and the great trochanter only when diseased, or when there is extensive disease of the pelvis."

About thirty years ago, whilst the fierce controversy regarding this operation was being carried on, the late Sir William (then Mr.) Fergusson and I had the good fortune to be able to trace to her lodging a young patient who had undergone this operation in King's College Hospital some months before. We heard of her death, and fortunately were able to make an examination of the parts. At that time Mr. Fergusson did not always remove the trochanter, but contented himself with excising the diseased head of the bone, and he had adopted the plan in the case in question. The wound had never healed up; there had been a continued discharge, and on denuding the parts after death we found that the section of the femur was quite healthy, but that there was a loose and necrosed bit of bone about the size of a nut in the acetabulum. The escape of this piece of bone had been entirely prevented by the trochanter, which formed a complete covering for the acetabulum. Mr. Fergusson was much impressed by this fact, and from that time he always insisted upon the propriety of removing the trochanter as well as the diseased head of the bone, even in instances where that process was healthy, and where there was not any disease in the acetabulum. Bearing in mind this interesting and instructive examination, and the lesson taught by it and impressed upon me by my late master, I have invariably adopted the plan of removing the trochanter, whether diseased or healthy.

I am, Sir, yours obedient,

Wimpole-street, W., May 24th, 1881. HENRY SMITH.

INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—At the meeting of the Pathological Society held on May 17th, my friend and colleague Dr. Charlewood Turner showed a specimen taken from a case of acute intestinal obstruction, on which I had operated at the London Hospital when the patient was in a very critical condition. During the operation, which was performed under the carbolic spray, and at which I had the advantage of the assistance of my friend and colleague Mr. Reeves, I found that the cause of the obstruction was of a twofold character. Some coils of intestine had passed through a loop formed by the attachment of a diverticulum to the anterior abdominal wall, and in that position the intestine had become twisted on itself. In the report of Dr. Turner's remarks the twist is not mentioned. I disengaged the intestine by drawing it back through the loop, and then untwisted it; but I deemed it better to leave the diverticulum, the length and attachment of which I could not clearly ascertain, as division of it would have considerably complicated a comparatively simple and brief operation. This is my reply to the clinical inquiry of the President of the Pathological Society, who asked if at the time of operation it was evident what the nature of the band was, and whether the surgeon was prepared to cut through it if necessary. Had I been aware that Dr. Turner intended showing the specimen at the Pathological Society on the 17th inst., I should have endeavoured to be present to furnish more conveniently the supplementary information required for the full elucidation of an instructive case, which was satisfactory at least in the coincidence of the results of the post-mortem examination with our interpretation of the cause of obstruction at the time of operation.

I am, Sir, yours &c.,
Finsbury-square, May 20th, 1881. WALTER RIVINGTON.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS AND THE OFFICE OF CORONER.

To the Editor of THE LANCET.

SIR,—As I have felt myself compelled to take the very unusual course of declining to present a petition to Parliament, I will feel much obliged if you will publish the enclosed correspondence. My sole desire is that the profession may have the opportunity of forming their own opinion on the action I have taken, prompted as it has been by a lifelong desire to place the claims of the well-educated physician in the very forefront of intellectual public life in all departments of the State in which his services may be called in requisition. It has ever been my motto, *Ιατρος γαρ ανηρ πολλων ανταξιος αλλων.*

Faithfully yours,
ROBERT D. LYONS.
House of Commons' Library, May 24th, 1881.

King and Queen's College of Physicians in Ireland,
Dublin, May 12th, 1881.

DEAR DR. LYONS,—I am directed by the College to request that you will kindly take charge of the petition of the College relating to the law of coroners in Ireland (which I forward to you by this post), and present it to the House at the earliest opportunity.

I have the honour to be, dear Dr. Lyons,
Yours very faithfully,
J. MAGEE FINNY, M.D., Registrar.
Robert D. Lyons, Esq., M.B., M.P.

House of Commons, May, 1881.

MY DEAR DR. FINNY,—I have received the petition of the College on the Coroner's Bill, and I beg leave to say that with the fullest sense of my duty to the College, and my most anxious desire to comply with its behests in all things, I feel very great difficulty in presenting a petition to the House of Commons which seeks to impose a disability on members of the medical profession in regard to a public office. I fear that this opens up a question of great gravity, and may be but the initiation of further disabilities, which many would be but too ready to impose on a profession not naturally strong in its powers of public protestation. I find that there is a large feeling in the metropolis in favour of medical men as coroners, a recent election having been successful in placing Dr. Thomas as the fourth in succession to Dr. Wakley in the office of coroner for Middlesex. On the committee to secure his election were—Dr. Farquharson, M.P., Chairman, Sir W. Jenner, and other men of note. Dr. Thomas was elected by 2500 to a little over 300, strikingly showing the feeling of the electors. The University of Oxford appoints a medical man as university coroner, and other examples may be readily found. I am myself of opinion that a well educated medical man, such as we hope the licentiate of the future shall always be, is fitted for any station in life, and from ancient times to the present day medical men have filled the highest official stations with great public advantage. The peerage and the great orders of honour have been largely illustrated from the ranks of medicine, and in both the administrative and combatant branches of the services. Names occur at once to my mind of men whom the State has delighted to honour. I would ask you to put my humble duty and most profound respects to the President and Fellows, and may beg them to reconsider the petition with a view to striking out Clause 2, or to relieve me from the deep embarrassment in which I should find myself placed, by asking another member of the House to present the petition if they deem it right to adhere to its present form.

Believe me, dear Dr. Finny, faithfully yours,
R. D. LYONS, F.K.Q.C.P.I.

To the Knights, Burgesses, and Commoners, in Parliament assembled, of the United Kingdom of Great Britain and Ireland, the humble petition of the President and Fellows of the King and Queen's College of Physicians in Ireland, sheweth,—

That a Bill has been introduced into your honourable House, intituled "A Bill to Amend the Law relating to Coroners in Ireland"—ordered to be printed 20th January, 1881. Your petitioners have observed with regret that the Bill proposes to continue the most objectionable features of the existing Coroners' Law in Ireland. Your petitioners are of opinion that the system of appointing coroners by vote of the ratepayers is not calculated to secure men with the requisite judicial qualities and technical knowledge for the efficient discharge of their highly responsible duties; and, as these duties are essentially of a judicial character, your petitioners consider coroners should be appointed on the same grounds, and in a similar manner, as other judicial functionaries. Your petitioners observe that while medical evidence is essential for the efficient conduct of a coroner's inquiry into the cause of death, it by no means follows that there should be a medical judge to try cases where medical evidence may form an essential portion of the case. On the contrary, the medical evidence should be provided by a skilled medical expert, who should be a medical jurist and pathologist; and, in the opinion of your petitioners, every Coroner should have such an officer attached to his Court. To the present system of employing "any legally qualified medical practitioner at or near the place," as provided by Act of Parliament (Vict. 9 & 10 c. 37, s. xxxii.), your petitioners take exception. Medical men engaged in general practice are seldom skilled pathologists or medical jurists, and therefore their evidence on special points is of comparatively little value. Your petitioners are of opinion that a Bill which does not contemplate the removal of the above-mentioned abuses in the existing Coroners' Law must prove unsatisfactory, and they therefore suggest that any measure for the reform of Coroners' Law which may receive the support of Her Majesty's Government should contain the following essential provisions:—1. That all Coroners should be appointed and paid by the Crown, as other judicial functionaries are at present. 2. *That every Coroner should be either a barrister-at-law or on the roll of solicitors.* 3. That every Coroner should have at least two deputies to take his place in case of absence or overwork, and that these deputies should be qualified in like manner as the Coroner. 4. That every Coroner should have a skilled medical expert attached to his court. Such expert should be appointed by the Crown, and should determine in all cases whether a post-mortem examination is or is not necessary, and should act as assessor to the Coroner. 5. That in all cases where a medical practitioner has been in attendance shortly before, at, or immediately after death, he should be examined as a witness, except in cases where he is charged with causing the death. 6. That all other matters of detail as to salary and retiring allowance of Coroners should be regulated on the usual principles followed in paying judicial officials. 7. That the medical expert should be paid partly by salary and partly by fees for each inquest. 8. That all other medical witnesses should be paid fees for attending and giving evidence, in addition to expenses incurred; and that such fees should be not less than three guineas a day. 9. That a proper place should be provided, where practicable, for the performance of post-mortem examinations in connexion with coroners' inquests. Your petitioners humbly pray your honourable House to amend the Bill in conformity with the foregoing suggestions; and your petitioners will ever pray.

Signed and sealed on behalf of the College,
GEORGE JOHNSTON, M.D. Edin., President.
May 12th, 1881. J. MAGEE FINNY, M.D. Dub., Registrar.

PHTHISIS AND HYDROPATHIC ESTABLISHMENTS: A CONTRIBUTION ON THE CAUSATION OF PHTHISIS.

To the Editor of THE LANCET.

SIR,—It is not at all uncommon to find consumption in association with caseous, slowly progressing suppuration of bone. Moreover, this well-observed fact appears to be in accordance with the well-known experiments of Villemin and others, illustrating the production of acute tuberculosis by the inoculation of caseous and non-caseous inflammatory products. But why do we find in practice that such results happen in some cases and not in others? This it is not always easy to explain, but many reasons have been given, such as the varying susceptibility of different constitutions, the accidental proximity of the infective material to the vascular or lymph systems, and the influence of the atmosphere and minute organisms. Those practitioners who are eager to steer their cases of caries of bone away from the shoals of phthisis are apt to look out for tangible assistance; and, believing that the following failure will show very clearly one of the ways how not to do it, I offer it as a contribution on the subject.

In November, 1880, a gentleman, aged twenty-five, consulted me and made the following complaints: a cough for the past ten months; hoarseness for four months; relaxation of bowels—two or three times a day—for six months; and loss of flesh—two stones in eighteen months. He handed me in writing his previous history and treatment, which it will be well to quote: "In January, 1879, I fell on the ice and bruised my face, my right knee and right breast. A month afterwards a swelling formed on the breast, getting larger up to June, when I went to ——— Hydropathic Establishment. There the doctor gave me the following orders. In diet strictly to be sparing in the use of flesh meats, taking such once a day only, and fish or fowl in preference twice or thrice a week; no soup or beef-tea, and eggs sparingly; to be sparing in the use of fat of all kinds, butter, milk, and foods made with milk; milk at supper to be especially avoided, and cornflour moulds preferable to milk puddings. Three meals allowed a day, and half a tumblerful of water to be taken before every meal. No luncheon or supper. Then as to baths. Every morning a rain bath, hot gradually reduced to cold, finishing with a canful of cold water dashed over the head and shoulders. Three times a week I had the ascending douche; this is like sitting on an ordinary W.C. seat, with the seat uncovered, and through a very small pipe, about a foot and a half below, water was projected against the anus. It was like a mild enema and brings on a desire for a motion very quickly. Every afternoon I had a spinal sitz bath—cold, deep—for ten minutes. On the three alternate days I took a Turkish bath, followed by a rain bath and descending douche. In addition certain body bandages worn to produce a 'crisis' created a sore on the abdomen, which discharged for over three weeks. Three days after admission the swelling was lanced, matter and blood escaping freely. With two days' intermission this treatment went on for ten weeks, and when I left on August 24th, 1879, the instructions were to carry out the same as far as possible."

My patient's story now runs on to the cough in Jan. 1880, and the development of laryngeal and intestinal complications. In Nov. 1880, there was softening of the upper part of the left lung, and early mischief in the right apex; there was ulceration of both vocal cords, and of the left margin of the epiglottis; and the signs were present which stamp diarrhœa as of tubercular origin. Over the fifth right rib, three inches from the sternum, was a sinus, almost healed over, communicating with carious disease of the rib. The patient grew steadily worse and died in February, 1881. His general health before the accident was good, he had a good family history, and he denied syphilis. Here, then, are certain clinical facts. A man of average health has a centre of infection accidentally set up. For ten weeks, and while the risks of infection were probably at their height, he was reduced by baths, exhausting both in character and in frequency. Lastly, he was restricted in his use of fats, milk, and nutrient foods, and advised so to continue. The deduction is that the infective material was first accidentally produced, the constitution was then as closely adapted to the bad influence as man could make it, the result being successful inoculation, phthisis, and death. The moral needs no telling.

I am, Sir, your obedient servant,

Ventnor, May, 1881. JAMES M. WILLIAMSON.

DR. KIDD ON THE CASE OF THE EARL OF BEACONSFIELD.

To the Editor of THE LANCET.

SIR,—In accordance with the love of large and liberal views, and the desire "to bring the catholic spirit into medicine, gathering all knowledge to the aid of suffering humanity," expressed by Dr. Kidd in his letter in last Saturday's LANCET, I have no doubt he will kindly favour your readers with a short clinical sketch of Lord Beaconsfield's case while under his care, including the treatment which enabled him to afford "*prompt and perfect relief*" after the two leading physicians of the day had "*failed to relieve the patient.*" The absence, hitherto, in the published reports of anything like a definite opinion of the pathology of his Lordship's case, would, I am sure, render such a sketch as I have suggested of much interest and value to your professional readers.

I am, Sir, very truly yours,

W. UNDERWOOD WHITNEY.

Great College-st., Westminster Abbey, May 23rd, 1881.

MEDICAL INDICES.

To the Editor of THE LANCET.

SIR,—With the growth of scientific periodical literature the question of the formation of indices becomes year by year more important.

You are aware that while the various Jahrbücher, Revues, and Records publish collected abstracts of many important papers, they are necessarily very imperfect, and that the only attempt to deal fully with the subject has been by the publishers of the Index Medicus, edited by Dr. Billings, of the Army Medical Department Library, Washington; but from what I hear there seems to be financial difficulties in the way of carrying on this meritorious publication.

The object of my letter is to ask whether the whole subject of indices is not one for international co-operation, for the promotion of which the assistance of Government may fairly be asked. Such a scheme would not limit itself to medical science, but would embrace all.

It has also occurred to me that our medical weekly papers would greatly facilitate research if they would publish complete indices to their whole series up to date.

I am, Sir, yours truly,

Birmingham, May 16th, 1881. ROBERT SAUNDBY, M.D.

IRELAND.

(*From our own Correspondent.*)

THE annual meeting of the Fellows to receive the report of the Council of the Royal College of Surgeons has been fixed for Saturday, the 4th June, a date more satisfactory to the provincial Fellows than that usually arranged. By holding it on the 4th proximo a large number of the Fellows who come to town to be present at the annual election of President, Vice-President, and Council, which will take place on Monday, the 6th June, will be able to attend without much inconvenience, to receive and discuss the annual report. To the names of Messrs. Bennett, Baker, and Meldon, mentioned last week as candidates for a seat in the Council, may now be added that of Dr. William Roe, lecturer on midwifery in the College of Surgeons. Canvassing for candidates for Council has of late years been exercised so openly, more especially within the walls of the College, that a strong expression of opinion against its continuance was adopted by the Council of the College last year; and it is probable that at the ensuing election arrangements will be made to enable Fellows to fill up their voting papers without being overlooked.

No date for the first matriculation examination has been fixed in the scheme adopted by the Senate of the Royal University of Ireland, and as far as can be learned, it is very improbable that it will take place this year. Before granting the necessary funds the scheme must be discussed in Parliament, and, considering the state of public business, it appears doubtful if much progress will be made this session in the matter. Further efforts are being used to secure the Queen's University in Ireland from being dissolved, as contemplated by the University Education (Ireland) Act of 1879, a result which it is considered by a large number would be an infraction of the vested rights of the graduates of that University, and injurious to the interests of academical education in Ireland. Besides this, Mr. Gladstone would seem, from his recent utterances, not to regard the formation of the new University with very much favour.

The College of Physicians have adopted certain recommendations of a committee appointed to consider the Coroners (Ireland) Bill, now before a committee of the House of Commons, and have requested Dr. Lyons, M.P. for Dublin, to present them to the House. They consider that coroners should be appointed in the same way as other judicial functionaries, their duties being essentially of a judicial character, and that they should be selected and paid by the Crown; that every coroner should have two deputies and also a skilled medical expert attached to his court, the latter official to be paid partly by salary and partly by fees. Further, that the practitioner in attendance shortly before, at, or immediately after death, should be examined as a witness, and receive not less than three guineas a day for his evidence. With most of these suggestions there will probably be little disagreement in the profession, but the recommendation that the coroner should be either a barrister-at-law or on the roll of solicitors is most startling as coming from a College of Physicians. This recommendation of the College has created considerable dissatisfaction, and must be regarded as a very unwise one.

The fifty-third annual meeting of the supporters of the Coombe Lying-in Hospital was held last Tuesday, presided over by the Right Hon. the Lord Mayor of Dublin. During the past year the expenditure exceeded the income by a sum of £252 16*s.*, and the bank account has been overdrawn by £1000. Last year 502 patients were admitted to the wards of the hospital, and 2165 labour cases were attended at their own homes. There were also 117 patients under treatment for diseases peculiar to women, and 6585 patients obtained advice and medicine at the dispensary. The hospital is situated in the midst of a poor, densely populated district, and the charity is one which has strong claims on the public. During the meeting, a letter was received from Dr. G. H. Kidd, enclosing a cheque for £100.

A new preparation, the iodate of quinine, has recently been introduced in Dublin by Dr. Cameron, city analyst; and many practitioners who have prescribed it speak highly of its efficacy in various affections, including neuralgia, chronic rheumatism, secondary syphilis, and some forms of pulmonary congestion. It is a granulated effervescing preparation, each drachm, the ordinary dose, containing two grains of the iodate.

The first of a series of lectures on Health, under the auspices of the Ladies' Sanitary Association, was given this week in the theatre of the Royal Dublin Society. The lecturer was the Registrar-General for Ireland, and the subject selected "The Causes of Disease and Death in Dublin."

Several cases of small-pox have recently been admitted into Queenstown Intercepting Hospital. Of these one has died, and the rest are progressing favourably.

The Lords of the Treasury have sanctioned a loan of £28,000 for the construction of waterworks for Sligo.

The thirty-ninth annual meeting of the Royal Medical Benevolent Fund Society of Ireland will be held at the Royal College of Surgeons on the 6th June, when the chair will be occupied by Mr. Alfred H. McClintock, President of the College.

PARIS.

(*From our own Correspondent.*)

THE Ministerial proposal to create six new chairs for so many Government *protégés* has not been received with favour at the Faculty of Medicine, and four of the would-be professors will be disappointed, at any rate for the present, in their hopes. A new clinical lectureship on Nervous Diseases will be instituted for Professor Charcot, and the second chair of Midwifery has also been accepted, but the four others on Dermatology, Public Sanitation, International Hygiene, and Medical Toxicology were negatived by the Faculty as of more than doubtful utility. This decision will be cordially ratified by the majority of the profession; for setting aside all sentimental interest in the prestige of the Paris school, it cannot but be felt that any public money at the disposal of the Ministry would be better employed in reducing the vexatious tax levied as *patente*, than in the creation of useless chairs, to satisfy the personal aspirations of certain influential practitioners.

Some statistics have already been issued by the new Municipal Laboratory, concerning the extent to which food adulteration is practised in this country. Of twenty samples of milk, seven were good, six passable, and seven bad; of three samples of beer, one only was good; of jams, eight samples out of nine were bad. Three samples of cider were all bad. Of one hundred and twenty-three specimens of wine examined, three were good, eighty-four bad, and the rest passable. The only article examined which was constantly of good quality was pork, four hams which had been sent for inspection being all declared free from trichinæ.

Apropos the ptomaines, M. Armand Gautier gives a new list of vegetable bases which can be distinguished from the cadaveric alkaloids by their chemical reaction to ferricyanide of potassium and a salt of iron. These are, anemonine, cryptopine, hellenine, quinidine, and sabadilline. In the cases of hyoscyamine, emetine, igosurine, veratrine, colchicine, nicotine, and apomorphine, the result of the test is doubtful. Experiments made with a number of toxic substances show that many artificial alkaloids and other bodies have the same behaviour in the presence of these chemicals, as the ptomaines; such, for instance, as naphthylamine, certain phenylic bases, and the pyrridic, hydropyrridic, allylic, and acetonic alkaloids; so that this test, although still of great value, loses much of its certainty.

At the Société Médicale des Hôpitaux, M. Lereboullet related a case of malignant diphtheria, treated successfully by hypodermic injections of pilocarpine. When the treatment was commenced, the little patient (a girl of eleven) was unable to swallow, and the urine, which was passed in very small quantity, was albuminous. Besides the injections, a spray of carbolic acid solution was constantly applied to the fauces, and ice was worn round the neck. Enemata of peptones were administered twice a day, and of carbolic acid once. Frictions of the surface with ether and spirit lotions were also employed. Pilocarpine also deserves a trial for the relief of the pains of locomotor ataxia and other spinal affections giving rise to severe paroxysmal suffering. Several observers are now using it in such cases, and the results, as far as they go, are satisfactory.

Obituary.

JAMES SHERLOCK, M.D., M.R.C.P.

ANOTHER valuable life has been prematurely taken from amongst us. Dr. Sherlock, who for twenty-seven years held the post of Physician to, and Medical Superintendent of, the Worcester City and County Asylum, died on Friday, the 13th inst., at the early age of fifty-three, after an illness of only three days.

For some time past Dr. Sherlock's health had given anxiety to his friends. A tendency to ill-developed gout, accompanied by a somewhat weak circulation, had lately shown itself, a condition generated doubtless by the incessant demands upon his strength, which nearly thirty years of conscientious discharge of the laborious and trying duties of a large asylum had made upon his constitution. Dr. Sherlock was seized with acute congestion of the liver on Tuesday, the 10th. On Thursday the base of the right lung became affected, the congestion extending during the night to the whole of both lungs, which overloaded the weakened heart, and death took place at half-past eleven on the following morning.

Dr. Sherlock was one of several excellent asylum superintendents who had the advantage of a training for the special work under the late Dr. Skae, of the Royal Edinburgh Asylum. After taking his degree at the University there, he became assistant to Dr. Skae, and as soon as he had made himself master of the details of asylum practice he was appointed superintendent of James Murray's Asylum at Perth. When still only twenty-six years of age, through the recommendation of Dr. Skae, supported by that of the then chairman, Mr. Curtler, he was appointed to the more responsible post at Worcester. At that time the inmates of the latter asylum numbered only about 250, whereas now they amount to nearly 800. The development by frequent enlargements to its present size, and the character, second to none in the kingdom, to which the asylum at Powick has attained, are mainly due to the unwearied efforts of Dr. Sherlock to attain for his asylum the highest point of efficiency. But he never suffered the laudable desire to keep down expenses to interfere with the efficiency as to means of cure, or with the comfort of unfortunate patients under his care. Consequently the loss of so valuable an officer is most keenly felt by the committee of management, who at all times have placed the utmost confidence in their superintendent; for whilst maintaining, as it is right they should do, a vigilant supervision of the work at the asylum, they have always most generously supported their chief medical officer throughout an unbroken connexion of twenty-seven years.

Dr. Sherlock leaves a widow (a connexion of Dr. Skae's) and six children to mourn his premature departure.

The funeral, which took place on Tuesday, the 17th, was attended by crowds of friends, amongst whom were several members of his committee and many of his professional brethren in Worcester and Malvern, by whom he was loved as a brother.

HUGH JAMESON, F.R.C.S. ENG.

DEPUTY INSPECTOR-GENERAL JAMESON was a distinguished member of the Naval Medical Service, who had seen in his youth much active service on the West Coast of Africa in the suppression of the slave trade, and was in 1840 surgeon of H.M.S. *Castor* at the battle of St. Jean d'Acre, where that ship suffered more than any other in the engagement. He afterwards served in the flag-ships on the Cape of Good Hope and Portsmouth stations, and subsequently was attached to the Naval hospital at Chatham and to Woolwich Dockyard. He retired from the service in 1864, and had since resided at Upper Norwood, where he died on the 16th inst. from paralysis and cardiac weakness. Highly educated and well informed, skilful in his profession, to which he had been trained at St. George's and Middlesex Hospitals by some of the most eminent surgeons of their day, Mr. Jameson enjoyed the respect and esteem of all who knew him. As for many years he held prominent naval appointments, his friends in the service are very numerous, who will regret in him the loss of an honourable, amiable, and accomplished gentleman. Mr. Jameson had three war service medals, and was elected an honorary Fellow of the Royal College of Surgeons in 1844 in compliment to his high character and professional reputation. His membership dates as far back as 1825, and we believe he was in his seventy-seventh year at the time of his decease.

THOS. BIRKHEAD OLDFIELD, M.R.C.S. ENG., L.S.A.

THE death of this much-esteemed and talented medical man took place at Heckmondwike on April 29th, at the age of sixty-two, from pyelitis. He had been a great sufferer for some seven years, and was only occasionally able to attend to practice. For five months previous to his decease he had been confined to bed. Born at Dewsbury Moor in 1818, he, after leaving school, was apprenticed to Mr. Senior, surgeon in Batley. He studied his profession at Leeds and Westminster Hospital, and with great assiduity and success. After a short term of practice at Wilsden, near Bradford, he settled at Heckmondwike, and for thirty-three years pursued his profession—to him a field in which his active mind took delight. He was a writer of no mean powers, on both professional and other subjects. In THE LANCET papers have appeared from his pen on "Placenta Prævia," "Hypertrophy of the Kidney," &c. The Yorkshire newspapers have been stored with articles from his pen on local antiquities, naturalist rambles, &c. Among these, "Heckmondwike, Past and Present," and "Heckmondwike Seventy Years Ago," are the chief. The deceased was buried on May 2nd, a large public funeral being organised by the Local Board to manifest their respect for their late officer of health. Mr. Oldfield was a widower, and leaves a family of four—one son and three daughters.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 18th inst.:—

Alexander, Frederick William, Hatton-garden.
Chard, R. A. Selway, Upton Lovell, Wilts.
Coutts, John Alfred, Aldridge-road.
Currie, Oswald James, Blackheath.
Dixon, George Frederick, Market Harborough.
Jones, William Wansborough, Macclesfield.
Owen, John Morgan, Fishguard, Pembrokeshire.
Rigby, John, L.S.A., Preston.
Rowley, Charles, Barnsley.
Shore, Herbert George, Stoke, Staffordshire.
Tripp, Charles L. H., Tiverton, Devon.
Wood, Louis Edmund, Marlborough, Wilts.

The following gentlemen were admitted Members of the College on the 19th inst.:—

Anderton, James Edwin, Blackheath.
Boswell, John Irvine, Guildford-place.
Buxton, Joseph Wilmot, Harrington-street.
Cranstone, William Lefevre, L.S.A., Hemel Hempstead.
Evans, Thomas G. C., Seaton, Devon.
Heyman, Frank Gibbins, L.R.C.P. Ed., Bristol.
Laurent, O. A. Eugene, Mauritius.
Mudge, Thomas, Hayle, Cornwall.
Medley, Harold T. D., Kensington-gardens-square.
Slater, William, Taunton, Somerset.
Tew, James Scott, L.S.A., Stourbridge, Worcestershire.
Udale, Joseph James, Finsbury-park.

Of the 95 candidates who were examined during last week, 42 passed to the satisfaction of the Court and obtained their diplomas; 7 passed in Surgery, and when qualified in Medicine will be admitted Members; the other 46, having failed to reach the required standard, were referred for six months' further professional study. Four candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical qualification recognised by the College, were also admitted Members.

The following gentlemen passed the First Part of the Professional Examination for the Fellowship at meetings of the Board of Examiners on the 21st, 23rd, 24th, and 25th inst.:—

W. S. A. Griffith, A. Dingley, Alfred J. Anderson, E. R. Williams, Edmund W. Roughton, and Frederick J. Paley, St. Bartholomew's Hospital; G. S. Watson and M. H. Bulteel, St. George's Hospital; W. Willis, Glasgow, Edinburgh, and Middlesex Hospital; Joseph Collier and Alexander Wilson, Owens College, Manchester; A. Q. Silcock, University College; Ernest E. Maddox, Edinburgh; Walter E. Wynter, Middlesex Hospital; Sidney Worthington and Wheelton Hind, Guy's Hospital; Charles A. Ballance, St. Thomas's Hospital, Henry W. Pigeon, Cambridge and Guy's Hospital; John C. Davies, London Hospital; John Y. Bostock, Cambridge; Herbert H. Ashdown, Edinburgh; D'Arcy A. Power, Oxon and St. Bartholomew's Hospital; William H. Horrocks, Liverpool and University College; Charles A. Morris, Cambridge; J. Donald, Charing-cross Hospital; Ernest Hudson, University College; Charles H. Wise, Queen's College, Galway, and Westminster Hospital; Walter T. Brooks, King's College; Edward Harrison, Cambridge; Louis A. Dunn, Guy's Hospital; David L. Jones, Charing-cross Hospital; and Joseph L. Hewer, St. Bartholomew's Hospital.

UNIVERSITY OF CAMBRIDGE.—The following have passed the Second Part of the Third Examination for the M.B. Degree:—

FIRST CLASS.

Coxwell, B.A., Christ's.
Lapage, M.A., Magdalen.
Mason, B.A., Pembroke.
Tooth, M.A., St. John's.

SECOND CLASS.

Birdwood, B.A., St. Peter's.
Standert, M.A., Corpus.
Wedmore, B.A., St. John's.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their Final Examination during the recent sittings of the Examiners, and were admitted Licentiates in Dental Surgery:—

Thos. Gaddes, Carlisle; Edw. Innes Ayton, Edinburgh; Maximilian Frank Simson, Lee, Kent; Hugh Fraser, Largs, Ayrshire; Henry Wyles, Leeds; Ernest Burt, Weymouth.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their Final Examination during the April sittings of the Examiners, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin.:—

James Booth Clarkson, Lancaster; James Daniel Ross, Co. Cork; William John Chichele Nourse, Isle of Wight; Robert Webster, Australia; William Boulter Broadribb Perrin, Somersetshire; James Johnstone, Dumfriesshire; Charles Swanston, Australia; David Carruthers, Dumfriesshire; James Arnott Hunter, Newcastle, Ontario; John Paulin, Peel, Isle of Man; Frank Fraser, Portsmouth; Robert Roberts, Chester; George Daunt, Co. Cork; Thomas Henry, Co. Tyrone; John Philip Sullivan, Dublin; James Hilditch Bradshaw, Lancaster; John Dugdale Astley, East Langden, Dover; George William Macartney, Colombo, Ceylon; Francis James Power, Maidstone; Francis Harper Treherne, London; David William Johnston, Whitehaven; Richard Clegg, Burnley; John Gainfort, Wexford; George Latham, Derby; William Abraham Dartwell, Rochester; Titus Holden Harwood, Burnley; Henry Dobson Osborne, Londonderry; David Duncan Main, Kirkmichael; James Murdoch Cameron, Edinburgh; George Henry Ainley, Todmorden; Charles Edward Watson, Hertfordshire; Edwin Brownlow, Ravendale, Lincoln; John Henry Dean, Sunderland; Frederick Francis German, Staffordshire; Thomas Hanson Smith, Keighley; William Huey, Adelaide, South Australia; Edmund James Armstrong Rogers, Grafton, Ontario, Canada; David William Noble, Co. Leitrim; James Satterthwaite, Lancashire; Charles Edward Lay, Suffolk; Isaac Kiddle, Surrey; Owen Frederick Seymour Evans, New South Wales; Eugene Joseph Geary, Cork; Isaac Holmes, Liverpool; Alexander Salvador Sabina Fernandes, India; Charles De Wolfe Heard, Prince Edward Island; Richard Æneas Delaney, Co. Mayo; Geoffrey M'Carthy, Co. Kerry; George Thomas Webbe, Poona; René Tubin Clément, Cape of Good Hope; Cornelius Maloney, Co. Limerick; John Murray, Alyth.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on May 19th:—

Butler, Thomas Edward, Cape of Good Hope.
Cockell, Edward Seaton, Amhurst-road, Hackney.
Craddock, Sidney Ernest, Upper Woburn-place.

The following gentleman also on the same day passed the Primary Professional Examination:—

Brewster, William, St. Bartholomew's Hospital.

HER MAJESTY has directed that 100lb. of cast-off linen be forwarded for the use of the Victoria Hospital for Children, Queen's-road, Chelsea.

AT the next general meeting of the Society of Public Analysts, to be held at Burlington House on June 1st, Mr. Wigner will introduce the subject of the Scale for the Valuation of Impurities in Drinking Waters, which has been in use by some of the members of the Society.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual meeting of this Society was held in the rooms of the Royal Medical and Chirurgical Society on May 18th. The President, Sir George Burrows, took the chair punctually at 5 P.M. After the election of officers for 1881-2, the report of the Court of Directors of the proceedings of the Society during 1880 was read by the secretary, from which it appeared that a sum of £2942 had been distributed during the past year among 60 widows, 15 orphans, and 3 recipients from the Copeland Fund. The expenses of the year were £177 11*s.* 3*d.* The total receipts available for payments of grants and expenses had been £3132 17*s.* 5*d.*; the grants and expenses had been £3119 12*s.* 3*d.* During the year one widow had died and two had become entitled to grants, two orphans had become ineligible for further grants, and three had been elected. Eight members had died and six had resigned, and only three new members had been elected, leaving a total of 375 members in the books at the end of the year. Dr. Semple, Dr. Self, and Dr. Augustus Brown, Dr. Cumberbatch, Mr. Spencer Watson, and Mr. Vasey were elected directors in the place of the six senior who retired. The customary votes of thanks having been passed, it was resolved that the Court of Directors should be requested to consider the desirability of sending a circular to all medical men residing within the area included within the former and present limits of the Society.

UNWHOLESOME FEEDING-BOTTLES.—Some feeding-bottles having a fetid odour were lately brought by Dr. du Mesnil from a *crèche* to the Paris Municipal Laboratory for examination. M. Fauvel found that the milk remaining in all smelt badly, was acid and half-coagulated; the globules were deformed, and numerous very lively bacteria, along with some vibriones, were present. On cutting open the caoutchouc tube throughout its length, coagulated milk with small organisms was met with; but a still more important fact was the presence in the nipple of a mass of vegetation of cryptogamic nature. Sown in whey, this developed considerably in a few days. A visitation of all the *crèches* was arranged by the police and medical authorities, and the following was the result:—Of 31 feeding-bottles examined in 10 *crèches*, 28 contained, in the nipple, the caoutchouc tube, and in some cases in the glass bottle, vegetations of the kind indicated, as well as bacteria, &c. Several that had been washed carefully, and were considered ready for use, still contained these cryptogams. Two feeding-bottles in a very bad state were found to contain pus and blood corpuscles; the children who had used them had injuries in the cavity of the mouth. It is thus probable that saliva enters the feeding-bottle, and its ferments are added to those of the milk. The acidity of the milk is attributed by M. Fauvel to the bacteria present. The influence of this condition of things in the development of intestinal affections, of which so many infants become the victims, seems to call for serious investigation.—*The Times.*

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the lates*

ADAMS, M. A., F.C.S., has been reappointed Public Analyst for the Borough of Hythe.

BENHAM, F. L., M.R.C.S.E., M.B., B.S., has been appointed Assistant Medical Officer to the New Infirmary, St. Marylebone, at a salary of £130 per annum, with furnished apartments, rations, and washing.

CARTER, R. B., F.R.C.S.E., has been appointed Ophthalmic Surgeon to the Bolingbroke House Hospital for Paying Patients, Wandsworth-common.

CLARK, T., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Dunster District of the Williton Union.

FAIRLEY, Mr. T., has been reappointed Public Analyst for the Liberty of Ripon.

GUNN, R. M., M.A., M.B., C.M., M.R.C.S.E., has been appointed Ophthalmic Surgeon to the North-West London Free Dispensary for Children.

HADDEN, W. B., M.D., M.R.C.S.E., has been appointed Physician to the St. George's and St. James's Dispensary, vice M. H. Lackersteen, M.D., resigned.

HALL, S., M.B., M.R.C.P., has been appointed Assistant-Physician to the Metropolitan Free Hospital.

LUNN, J. R., M.R.C.S.E., L.R.C.P., has been appointed Medical Officer to the New Infirmary, St. Marylebone, at a salary of £450 per annum, with unfurnished house, coals, gas, and washing.

MICKLE, D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Peckhill District of the Thirsk Union.

MORGAN, W. L., M.A., M.R.C.S.E., has been appointed Surgeon to the Radcliffe Infirmary, Oxford.

NANCE, Mr. H. C., has been appointed House-Surgeon to the Whitehaven and West Cumberland Infirmary and Fever Hospital, vice Hoyle, resigned.

OLIVER, J., M.B., C.M., has been appointed House-Surgeon to the Durham County Hospital.

RICHARDSON, R. T., M.R.C.S.E., L.S.A.L., has been appointed Assistant Medical Officer to the Leeds Union Infirmary, vice Mr. H. C. Oakley, resigned.

RICHARDSON, T. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Fourth District of the Norwich Union.

SUTTON, Mr. T., has been reappointed Public Analyst for the County of Norfolk.

WALMESLEY, F. H., M.D., has been appointed Senior Assistant Medical Officer to the Metropolitan Asylum, Leavesden, vice C. A. Mercier, M.B., F.R.C.S., resigned.

WHITEHEAD, H. R., F.R.C.S.E., has been appointed Assistant-Surgeon to the Royal Westminster Ophthalmic Hospital.

Births, Marriages, and Deaths.

BIRTHS.

CUNNINGHAM.—On the 17th inst., at Blacket-place, Newington, Edinburgh, the wife of Deputy Surgeon-General Cunningham, of a son.

EDMUNDS.—On the 21st inst., at Cwmbran House, near Newport, Mon., the wife of Richard Edmunds, M.R.C.S.E., L.R.C.P., of a daughter.

FENN.—On the 19th inst., at Richmond, Surrey, the wife of Edward L. Fenn, Esq., M.D., of a son.

GALLOWAY.—On the 10th inst., at Epping, the wife of Arthur Wilton Galloway, M.R.C.S.E., L.R.C.P., of a son.

HARDWICK.—On the 19th inst., at Pillar House, Needham Market, Suffolk, the wife of Fredk. S. Hardwick, M.D., of a son.

JENKINS.—On the 12th inst., at Liskeard, the wife of J. H. Jenkins, M.R.C.S.E., L.R.C.P.Ed., of a son.

VIVIAN.—On the 22nd inst., at Chase Side, Southgate, N., the wife of R. T. Vivian, M.R.C.S.E., L.R.C.P.E., of a son.

MARRIAGES.

ALLEN—TURNER.—On the 19th inst., at the Parish Church of St. James, Grimsby, by the Rev. J. P. Young, M.A., Vicar, Thos. W. J. Allen, L.R.C.P.L., M.R.C.S.E., to Jennie, youngest daughter of the late George Byron Turner, Esq. No cards.

BLANEY—LAFONE.—On the 17th inst., at SS. Mary and George Church, Cockington, Torquay, by the Rev. W. Law, M.A., assisted by the Rev. Henry Fairley, M.A., of All Saints, Daventry, and the Rev. H. L. Bellhouse, M.A. (cousin of the bride), James Blaney, M.R.C.S.E., of Penryn, Cornwall, to Mercy Annie Constance, daughter of the late S. F. Lafone, of Monte Video.

FARNELL—COLGATE.—On the 24th inst., at St. Saviour's, Eastbourne, by the Rev. J. H. Cheadle, M.A., Minor Canon of Westminster, assisted by the Rev. T. W. Mylne, Curate of St. Saviour's, Henry Dawson Farnell, M.R.C.S.E., of The Goffs, Eastbourne, to Mary, daughter of Robert Colgate, F.R.C.S., of Hempstead House, Eastbourne.

FISHER—POLLARD.—On the 21st inst., at the Pro-Cathedral, Demerara, Frank Charles Fisher, of the Government Medical Service, to Mary Eliza Rosalie, youngest daughter of the late W. B. Pollard, Esq., Auditor-General of British Guiana.

WYATT—SHEPHERD.—On the 18th inst., at St. Augustine's, Highbury, William Thomas Wyatt, M.A., M.B., of Stamford-hill (son of Sir William Henry Wyatt), to Edith Anne, fourth daughter of the late Edw. Shepherd, Esq., of Aberdeen-park, Highbury, Magistrate for the County of Middlesex.

DEATHS.

BROWNE.—On the 22nd ult., at Ebor Lodge, Albion-road, Stoke Newington, Henry Browne, L.R.C.P. & L.S.A.L., aged 36.

CHARLETON.—At Gloucester, of heart disease, G. W. Charleton, M.D., F.R.C.S.E.

FRASER.—On the 3rd ult., at Brockville, Ontario, Allan Hugh Fraser, M.D., aged 52.

LYLE.—On the 24th inst., at 102, Rye-hill, Newcastle-on-Tyne, Robert Lyle, M.D.

PEILE.—On the 7th inst., on board the s.s. *Agamemnon*, in the Suez Canal, off Ismailia, Bransby Cooper Peile, M.R.C.S.E., L.S.A.L., of Shepherd's-bush (son of the late Thomas Hanson Peile, Esq., and grandson of the late William Babington, M.D., F.R.S.), in his 55th year.

ROPER.—On the 23rd inst., at Exeter, Charles H. Roper, M.R.C.S.E., L.S.A.L., aged 53.

WHITAKER.—On the 19th inst., at North Walsham, James Sealy Whitaker, L.S.A.L., M.R.C.S.E., eldest son of the late James Samms Whitaker, M.R.C.S.E., F.L.S., aged 29.

WHITLEY.—On the 20th inst., at Bedlington Vicarage, George Whitley, M.D., aged 65.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, May 30.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ A.M. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

St. Mark's Hospital.—Operations, 2 P.M.; on Tuesday, 9 A.M.

Society for the Encouragement of Arts, Manufactures, and Commerce. — Cantor Lectures: Mr. R. Brudenell Carter, "On Colour Blindness and its Influence upon various Industries."

Tuesday, May 31.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 3 P.M.

Royal Institution.—3 P.M. Professor Dewar, "On Non-Metallic Elements."

Wednesday, June 1.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ P.M.

King's College Hospital. — Operations, 2 P.M., and on Saturday at 1 P.M.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 P.M.

University College Hospital. — Operations, 2 P.M., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children. — Operations 2½ P.M.

Epidemiological Society.—8 P.M. Annual General Meeting:—Election of Office-Bearers. Annual Report of the Council.—Mr. George Fleming, "On the Transmissibility of Diphtheria from Animals to Mankind."

Obstetrical Society of London.—8 P.M. Specimens will be shown by Dr. Wiltshire, Dr. Brunton, Dr. Godson, and others.—Dr. J. Hickinbotham, "On Notes on a Case of Placenta Prævia complicated by a large Myoma."—Dr. Mansell Moullin, "On a Case of General Œdema without Anasarca."—Dr. Barnes, "On a Note on the so-called Lithopædion."

Thursday, June 2.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—1½ P.M. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 P.M.

Central London Ophthalmic Hospital. — Operations, 2 P.M., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2½ P.M.

Royal Institution.—3 P.M. Professor Tyndall, "On Magnetism."

Friday, June 3.

St. George's Hospital.—Ophthalmic Operations, 1½ P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 2 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

Royal Institution.—8 P.M. Professor W. G. Adams, "On Magnetic Disturbance, Auroræ, and Earth Currents."

Saturday, June 4.

Royal Free Hospital.—Operations, 2 P.M.

Royal Institution.—3 P.M. Professor C. E. Turner, "On Russian Literature: Gogol."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE half-yearly Primary or Anatomical and Physiological Examination for the Fellowship of the College was commenced on the 20th instant, when the following questions on Physiology were submitted to the ninety-eight candidates—viz., seven seniors, twelve juniors, and four who had not passed any examination. The candidates were required to answer at least three of the four questions in the time allowed—viz., from 11 A.M. to 2 P.M.:—

1. Describe the minute structure of the two outer layers of the retina. What are their functions? Describe the effects of light upon them in the living eye.
2. Contrast the tension of the oxygen and carbon dioxide contained in venous and arterial blood respectively with the partial pressure of those gases in the pulmonary alveoli. Compare the gas-interchange which takes place normally with that which occurs in suffocation.
3. Enumerate the different kinds of proteid substances found in the human body. State where they are found, and give their distinctive characters.
4. Describe the formation of a blood-clot. Upon what does it depend? Mention the circumstances under which the blood may clot within the vessels, and describe the stages of the process. How may the coagulation of shed blood be prevented?

The following were the questions on Anatomy, from 3 to 6 P.M., and three out of the four to be answered in that time:—

1. Describe the arches of the foot, and the ligaments and muscles by which they are maintained.
2. Describe the dissection necessary to expose the left vertebral artery from its origin to its entrance into the skull.
3. Describe the spinal column as a whole:—First, in reference to its curves, and the manner in which the several vertebræ are modified in shape in association with these curves; secondly, in reference to the movements which take place in its different parts, and the means by which these movements are effected and regulated.
4. The subject being in the supine position, describe the dissection by which you would expose the whole of the obturator externus muscle and its tendon.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—Will you allow me to ask the influence of any of your readers who may be in a position to assist on behalf of Ethel Breeze, a twin daughter of the late R. Goodwin Breeze, M.R.C.S., who is a candidate for election on June 10th into the Royal Asylum of St. Anne's Society. Mr. Breeze was a former student of University College, London, and practised for some years at East Finchley, where he died after a short illness in September, 1880, leaving a widow and ten children in very reduced circumstances. The case is one which has been investigated not only by the committee of the St. Anne's Society, but also by the committee of the Medical Benevolent College, who had recently a presentation to St. Anne's to bestow, but unfortunately had a more urgent case before them. The urgency of the case of Ethel Breeze has since that time been increased by the fact that the mother has lost an imbecile inmate from whom a large proportion of her income was derived, and I venture, therefore, to ask my medical brethren for any influence they may be able to exert on her behalf.

I am, Sir, yours obediently,

Cavendish-square, May 23rd, 1881. CHRISTOPHER HEATH.

P.S.—Since the above letter was written a friend of the family has undertaken to purchase the admission of the other twin provided Ethel be elected.

ROYAL MEDICAL BENEVOLENT COLLEGE.

AN old correspondent who annually draws attention in our pages to the facts so well described in the last number of THE LANCET by Dr. Timothy Richardson, in confirming all he has there stated, adds that out of the fourteen candidates for the pensionerships in the above institution, only four had been subscribers; and out of the forty candidates for foundation scholarships, the parents of only five had been subscribers. Like many of his friends, he always gives his votes to those who have been subscribers. On the present occasion he certainly would not support the house-list.

DESQUAMATION AFTER DRUGS AND AFTER SCARLATINA.

To the Editor of THE LANCET.

SIR,—In your number of April 23rd I noticed a letter signed "Vigilans," which has reference to desquamation of the skin resulting from diseased conditions other than measles, scarlet fever, &c. I have a case under my care at present which may perhaps be thought interesting as bearing upon this question. A lady aged seventy-three, whilst nursing her brother (a medical man), fell ill with what I considered to be rheumatic fever. Several joints were affected, profuse acid perspiration, and long-continued high pyrexia accompanied the malady. The temperature was for a long time unaffected by the remedies—salicine, quinine, &c.—which were used, and remained even after the swelling in the joints had subsided as high as 101° at noon for some days. After convalescence was established, and the fever had abated, I was surprised to find that my patient was "peeling," as she termed it, "from head to foot." The desquamation was in most places branny, and from the soles of the feet and palms of the hand larger portions, some the size of a shilling, came away. She had had scarlet fever when a child, and during the present illness had no throat symptoms, nor was there any rash. Her tongue throughout the whole time was like raw beef. I need hardly say that no drugs of the nature of turpentine were used, so that that theory of desquamation was of no value here.

I may mention that after an acute attack of croupous pneumonia, which I had about ten years ago, I scaled all over, and can well remember the large desquamatory patches coming off my hands and feet. It behoves all members of the profession to examine more closely into the nature of this process, so that in future its clinical importance may be justly estimated.—I remain, Sir, yours faithfully,

Canonbury-lane, N., May 18th, 1881. A. GEORGE BATEMAN.

To the Editor of THE LANCET.

SIR,—Your correspondent, "Vigilans," quarantined his patient on very slight grounds. With, as "Vigilans" says, a slow pulse, normal temperature, and no other history of scarlatina beyond desquamation of the hands, it was unnecessary. "Vigilans" does not tell us whether the desquamation was palmar or dorsal, or whether he noticed the feet and other parts of the body. I quite fail to see that "marked desquamation in large flakes of the skin of the hands so strongly suggests a scarlatinous poison."

There are many border cases in which there is a doubtful rash, which may or may not be followed by it. In a household of four children, three had well-marked rötheln, and no desquamation; the fourth child had the same general symptoms as the others, but the rash was confined to the legs, and showed itself in immense purpuric patches, which alone desquamated. Again, of three children in another house, the first had well marked diphtheria, no desquamation; the second, ten days after the first, had true scarlatina and desquamation; the third, four days after the second, had simple tonsillitis, no rash or desquamation. I have observed them carefully for seven weeks since the first one was attacked, and am certain that the first and third were entirely free from it.

I find that desquamation is a frequent sequela of disease. It occurs in many cases of continued pyrexia from whatever cause, but frequently after acute pneumonia and continued fevers. Locally it takes place after gout, erysipelas, some forms of erythema, and after the application of cataplasms. The hands of a patient compelled to take rest desquamate, and it is a common thing in newly-born children. Given other symptoms it may confirm a diagnosis of scarlatina, but alone it most assuredly is not diagnostic.

I infer from observations that desquamation is due to continued pyrexia, and that any disease, local or general, septic or otherwise, which is accompanied by superficial capillary congestion, may, if not quickly relieved by diaphoresis, be followed by desquamation.

I am, Sir, yours faithfully,

A. M. ROBERTS, L.K. & Q.C.P.I.

Buckhurst-hill, April 26th, 1881.

To the Editor of THE LANCET.

SIR,—The interest in the discussion on desquamation after scarlet fever in your columns does not appear to have yet ceased, as evidenced by the interesting letter of "Vigilans" and your own leading article in the same week. "Vigilans" asks for the experience of others as to the occurrence of desquamation after the administration of certain drugs.

A few weeks ago I saw a young man suffering from a profuse erythematous eruption from taking copaiba, and this was followed by the most copious desquamation from head to foot. In the late discussion have not two points been lost sight of?—first, that the desquamation is the result of the erythematous eruption; and, secondly, that we have no sufficient reason for concluding that the desquamating epidermis continues to be the bearer of infective particles, however long the proces may continue, or that it may not be disinfected before it separates?

That the desquamation is the consequence of the erythema irrespective of the cause of the latter appears from its following erythema resulting from other causes, and also from the desquamation being proportionate (*cœteris paribus*) to the intensity of the erythema, and not to that of the other results of the scarlet fever. I have heard and read of desquamation following scarlet fever when there has been no eruption but in a large experience have never seen such a thing to my knowledge and its occurrence under those circumstances is not in accordance with the notably direct proportion they bear to each other when an eruption has existed. A very considerable eruption I have often found escape the notice of the parents of the patient.

With regard to the second point, I may observe that I have so often seen children whose cuticles were still desquamating playing freely with others that I have learned not to forbid it, provided three weeks have elapsed from the onset of the fever, that all other symptoms of it have wholly disappeared, and that methodical inunction with oil and carbolic acid and bathing have been practised.—Your obedient servant,

Hackney, April 23rd, 1881. EDWARD G. GILBERT.

Mr. Loftus Lambert need not be prematurely alarmed on the subject.

A Newsroom Reader.—THE LANCET of July 17th, 1880, contains an article on the subject by the author named. Refer also to a paper read at the Clinical Society, and reported in THE LANCET, Dec. 4th, 1880.

FOREIGN PRACTITIONERS IN FRANCE.

F.R.C.S. would have to submit his diplomas to the Minister of Public Instruction, together with the certificates of course of study. If satisfied, the minister would then authorise his being admitted to five final examinations. See "Hardwicke on Medical Education and Practice in all parts of the World" (Churchills).

SIMPLE METHOD FOR REDUCTION OF DISLOCATION OF SHOULDER-JOINT.

To the Editor of THE LANCET.

SIR,—In recent numbers of THE LANCET I have observed descriptions of numerous mechanical contrivances for the treatment of dislocation of the shoulder-joint, and am thus led to give my own experience in treating such cases.

While admitting the theoretical as well as the mechanical grounds on which the various writers base the merits of their individual contrivances, I cannot help thinking that for the most part they are superfluous and unnecessary in all but very exceptional cases. In a considerable experience in this department of minor surgery, both in hospital and private practice, I have never known the following method of treatment to fail—a method so simple as almost to demand an apology for publishing its details, but one to which I have never seen any reference in the ordinary text-books. It may be called the method of reduction by unaided manipulation, and in no important respects does it differ from the similar means taken for the treatment of dislocation of the hip-joint, while the results are equally gratifying, and the triumph of skill and science over main force is equally apparent. Supposing the left limb to be dislocated, the surgeon standing on the affected side of the patient grasps the limb at the elbow-joint with his right hand, and places the thumb of his left hand on the misplaced head of the humerus. Abducting the limb from the side, and making a fair amount of extension, he now calls away the patient's attention from himself so as to relax the muscular system in some measure, and, taking advantage of this relaxation, he rotates the limb externally, aiding the reduction by, at the same time, pressing with his left thumb on the misplaced head of the bone. The only difference when the right is the affected side is that the operator's hands have to be transposed.

In the last ten cases of dislocation of the shoulder-joint that have come under my care the condition was rectified at the first attempt under the manipulation I have indicated; in eight of the cases without the use of any anæsthetic. In the remaining two, one was in the person of a very muscular man, while in the other the condition had existed for fifteen days, and in neither of these cases could I accomplish the reduction until the patients' muscular systems had been relaxed by chloroform, though I have never found it necessary to push the anæsthetic past this stage; but even in the case in which the dislocation had been neglected for a fortnight I found that manipulation was quite sufficient.

I do not claim any originality in commending this simple method to the profession, but I would say that its simplicity ought to commend itself to everyone, while as to its practical utility in the great majority of cases I think I have a right to speak positively. It is a mistake to suppose that a large amount of muscular energy requires to be expended by the operator in accomplishing the reduction of the dislocation in this way, for, as I said before, it is skill, not force, that will accomplish the desired end; and personally I cannot claim to be possessed of herculean muscularity. The time-honoured procedure of making traction on the limb with the foot in the axilla forming the fulcrum, will no doubt, from its very orthodoxy, always have plenty of supporters, but at best the position which the operator has to adopt is anything but a dignified one, while the method I now indicate and invariably adopt is not nearly so trying or painful to the unfortunate patient, either mentally or physically. I may also add that I have reduced a dislocation of the shoulder by the manipulation method, without any anæsthetic, on the second day, after the foot-in-axilla method had been vainly tried on two occasions under chloroform.—I am, Sir, yours, &c.,

Liverpool, April, 1881. S. RUTHERFORD MACPHAIL, M.B. Ed.

"UNQUALIFIED ASSISTANTS."

WE have received a large number of letters on this subject, raised by "Veritas" in our issue of May 14th. We cannot print a tithe of these communications, but give extracts from some of them.

Mr. Charles F. Rideal, of Thetford, writes:—"It cannot be denied that spirit and self-respect are much wanted in the medical profession, as, indeed, it is in all professions and occupations of the present day, but at the same time such a letter as the one 'Veritas' has contributed to your columns does not in the slightest degree tend to modify the existent evil, but rather aggravates it by the attack upon a class which does not merit his insinuations. I fully agree with him that medical reform has a wide range, but I ask him if he thinks the denunciation of 'unqualified assistants' assists him in any way to narrow its limits or to demonstrate its inner life. In all deference to him, I will undertake to say that out of the twenty medical men who grieve 'Veritas' by employing the ten 'unqualified assistants,' not one of them has granted a certificate of death without having seen the patient; no, the medical practitioner of the day is too careful for that. If this is not so, and it is within the cognisance of 'Veritas,' why does he not, in justice to himself and the profession at large, have the Act of 'law's defiance' sifted through to light, and thereby 'practically' carry out that which he professes to desire—i.e., medical reform? Where will 'Veritas' draw the line as to the term unqualified? This term varies from the 'green youth' leaving school to the man reading for his Final; the latter may be an individual who has obtained 'degrees;' he may have distinguished himself in literature, chemistry, pharmacy, or many other subjects; but purely for the love of the profession he is following may have cast all his previous distinctions aside. 'Veritas' must not forget that all these are included under the heading of 'unqualified.' Owing to the stringent examination required by the Pharmaceutical Society for the qualification of chemists, there is every reason to hope that those who are 'promoted' are in point of 'practical' experience far more advanced in medicine than are the many who literally cannot mix their own physic, but who hold the diplomas of our medical licensing bodies, and are just the very men who are suitable to be drafted into the rank and file of the medical profession, if only for their experience. Let 'Veritas' take the trouble of inquiring from them their experiences of 'unqualified assistants,' and I feel assured that he will hear to the effect that the unqualified man is generally a hard-working, intelligent fellow, who is desirous of advancing himself in every way, and that he is steady, and satisfies his employer's patients."

M.B. Univ. Dub., L.R.C.S.I., writes:—"In your issue of last Saturday 'Veritas' wisely remarks, we need medical reform on the above subject, and nothing short of the total abolition of unqualified assistants ought to satisfy the public and the profession. If you will allow me space to relate my experience, which is the experience of hundreds of thoroughly qualified men, you will, I think, admit I have given a clear proof of the fact that the profession is overcrowded by *unqualified assistants*. Notwithstanding the high degrees I possess (degrees which cost nearly £450 and five years' hard study to obtain), I was two months before I got an assistancy, and then I had to be content with £100 a year and furnished rooms. After remaining two years with my principal, who was invalided, he recovered sufficiently to be enabled to dispense with my services, employing some kind of a dispenser, &c., giving me, however, a most excellent testimonial. For three months, through the medium of THE LANCET and agents, I endeavoured to obtain another assistancy, but failed, except indeed I consider the offer of £80 yearly, out-door a fair remuneration for my qualifications and attainments. I think this matter of unqualified assistants is one requiring the strenuous efforts of the eminent men in the profession to put down; and I maintain they ought to use those efforts on behalf of their poorer and younger professional brethren."

O. U. I. remarks:—"In any legislation for the total abolition of the calling of the unqualified assistant, much consideration and discrimination must be needed, inasmuch as any sudden and arbitrary measure with that object would have the effect of depriving a great many men of their only means of subsistence, and of throwing a large number of families helpless upon the world. 'Veritas' ought to suggest some scheme for meeting such cases of exigence when he propounds as his notion of reform 'that the abolition of unqualified assistants is imperatively demanded in the interests of the public and the profession.' There are scores of young men at the present time pursuing their studies at the various hospitals, who would hardly be able to do so could they not employ a portion of their time as unqualified assistants, in return for board and lodging; and there are hundreds of medical men, now in high repute in the profession, and good position in society, who have raised themselves from the unqualified ranks solely by their own indomitable industry, steadiness, and perseverance. Is it entirely desirable indiscriminately to exclude all such meritorious persons, and to admit to the profession only those who may happen to have a few hundreds of pounds to spare? The second subject touched upon by 'Veritas' is one not in any way affecting assistants of any class, but principals; and I freely admit that the recovery of professional fees by instalments through the medium of a collector must seem a somewhat undignified mode of procedure to those unaccustomed to it. I speak from considerable personal experience when I assert that in many, if not most of the large manufacturing districts, a medical man practising among the operative and labouring classes must either consent to have his outstanding accounts 'collected' or go without three-fourths of the income derivable from such sources. The statement that 'there is no trade conducted on such principles,' does not hold good everywhere. I have seen the same person collecting for a medical man and for tradesmen on the same Saturday afternoon, and receive money for each from the same 'client.'"

PUPILAGE.

An Old Pupil, in a letter too long for insertion, argues strongly against the system of even a short pupilage, either before the commencement of his medical studies, or in the middle of them. He thinks any work the pupil might be called to would be of the nature of unprofitable drudgery, and that he would learn, not the science of medicine, but the art of pleasing and ready prescribing. Even pupilage at the end of the curriculum he thinks would not be more beneficial. "When we consider that a practitioner who has been engaged in professional work away from educational centres for ten years is old in the profession, it is hardly likely that a young man fresh from the latest scientific training can learn much or have much in common with such a practitioner." Our correspondent does scant justice here to the experienced practitioner. He is not likely to be so foolish as to undervalue the knowledge acquired through recent methods by a pupil at the hospital, and from a succession of such pupils as a system of pupilage would imply would be kept *au courant* with advancing science, besides having a clinical experience different altogether from that which a student has gone through in hospital work. Our correspondent admits that the dispensaries in educational centres afford ample opportunities for instructing young men in the practice of their profession. The subject of pupilage is coming up again, and though there will never be a reversion to pupilage in its old form, there is an extensive consensus of opinion in favour of a short pupilage at a more or less advanced period of medical study.

MEDICAL LEGISLATION IN NEW BRUNSWICK.

THE medical profession in New Brunswick is (says the *Canada Lancet*) to be congratulated on having succeeded in getting a Medical Bill through the Legislature this session, which will stop for the future the free trade in medicine which has heretofore existed in this province. A matriculation examination and a four years' course are among the requirements for future registration.

W. T. P. should consult the article on Books in the Students' Number of THE LANCET, published in September last.

Mr. T. H. Moorhead.—Probably any instrument-maker would undertake to supply the respirator.

Lieut.-Colonel Walker should consult the Medical Directory. We cannot recommend particular physicians or surgeons.

Odd Fellow.—We cannot assist our correspondent.

Tricked.—We regret that the tone of our correspondent's letter is so objectionable and some of the statements and references so far from correct that we cannot give it a place in our columns.

"THE BLOOD OF SAINT JANUARIUS."

To the Editor of THE LANCET.

SIR,—Since the marvellous oxygenation and liquefaction of the hermetically sealed blood of Saint Januarius are again reported to have recently taken place at Naples before the Cardinal Archbishop and an august assemblage of the Roman Catholic faithful, I should like to know if any of your readers can inform me whether or not this reported bi-annual miracle has ever been submitted to the ordeal of unbiased scientific inquiry and rational physiological examination.

I am, Sir, yours obediently,
Park-place, Leeds, May 16th, 1881. A. CLARENCE FOSTER.

A NEW TITLE FOR UNQUALIFIED PRACTITIONERS IN THE COUNTY OF DURHAM.

A correspondent, *M.B.*, states that in some of the colliery districts in Durham several men are practising and signing death certificates, using the title M.S., which would at first sight imply master in surgery, but in the case of these gentlemen means simply medical student! This appears incredible. It should be enough to direct public attention to such a proceeding to stop it.

AMERICAN WOMEN DOCTORS.

FROM a pecuniary point of view the choice of a medical career by certain ladies in America would appear not to have been a happy one. The results of an inquiry by the Dean of the Woman's Medical College in Pennsylvania show that three-fourths of the number (189) of graduates of that college who responded to appeals for information on the point are not earning more than three thousand dollars a year each, while three only have gained an independence by their practice.

Mr. Henry Bingham.—We believe it is customary for the bodies examining for diplomas in sanitary science to recommend the works to be studied. Write to the proper officer in Cambridge, and obtain the suggestions as to the studies for the certificate of that university, or to the registrar of the body selected.

Mr. W. Barr.—There is nothing special about the operation, which is one that is performed by ophthalmic surgeons in suitable cases.

THE TREATMENT OF PSORIASIS BY TURPENTINE.

To the Editor of THE LANCET.

SIR,—The treatment of psoriasis by turpentine, as stated by Dr. Crocker in this week's LANCET, is a valuable addition to our therapeutics in this often obstinate cutaneous disease, but requires more extensive trial. Your correspondent seems to think that its odour is its chief objection, but this can be easily remedied by the use of an equal part of the essential oil of lemons, which in itself is chemically identical with that of turpentine. The essential oil has the effect of destroying the terebinthinate odour without impairing its efficacy.

I am, Sir, yours truly,
Mildmay-park, N., May 10th, 1881. JAMES WILLIAMSON, M.D.

THE NATIONAL VACCINE ESTABLISHMENT AND ITS LYMPH.

To the Editor of THE LANCET.

SIR,—After reading the correspondence in THE LANCET of May 21st about the bad quality of the lymph obtained from the National Vaccine Establishment, I find, on looking over my register, the following note opposite some unsuccessful cases, which cases I had relied on for future supply—viz., on March 26th, 1880:—"Unsuccessful; lymph obtained from National Vaccine Establishment; bad as usual." This note in the register went before the guardians of our union and the Government inspector. I may add I have not since applied for lymph from the National Vaccine Establishment.—I am, Sir, yours faithfully,
Bloxham, Oxon, May 23rd, 1881. J. COLEGRAVE.

To the Editor of THE LANCET.

SIR,—During the past fourteen years I have at different times had both points and tubes of vaccine lymph from the National Vaccine Establishment, and, in justice to this institution, think it only fair to state I have never yet failed with the lymph supplied by them. Roughly speaking, I should say I have been furnished with lymph from this establishment at least twenty times.

I am, Sir, yours faithfully,
Cheetham, Manchester, May 23rd, 1881. J. WESTMORLAND.

To the Editor of THE LANCET.

SIR,—I am sorry to say I can fully endorse the complaint made by "A Public Vaccinator" with regard to the lymph from the National Vaccine Establishment. I have recently had two supplies, neither of which had the slightest effect.—I am, Sir, yours, &c.,
April 18th, 1881. ANOTHER PUBLIC VACCINATOR OF 40 YEARS' STANDING.

To the Editor of THE LANCET.

SIR,—In reply to the question of your correspondent, "A Public Vaccinator," I can say that I have generally found the lymph supplied by the National Vaccine Establishment useless—that is to say, I much more frequently fail than succeed in obtaining vesicles from it, however freely it may be used. I cannot help thinking that this lymph is largely diluted, and thus the National Vaccine Establishment becomes but another sham.

I am, Sir, yours faithfully,
May 17th, 1881. A GENERAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—In answer to the query of "A Public Vaccinator," I may say that twelve cases of primary vaccination in the East Hertford district entirely failed when I used the lymph supplied by the National Vaccine Establishment. When I used the lymph supplied me by a friend, and taken from his own cases, success followed at once.

I am, Sir, yours, &c.,
May, 1881. QUALIFIED ASSISTANT CERTIFIED TO VACCINATE.

UNQUALIFIED ASSISTANTS.

A Country G.P. justifies the employment of unqualified practitioners under strict supervision, by qualified men, and thinks them preferable often to young men who have just passed their examinations.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. G. Berry, Edinburgh; Dr. R. Foss, Stockton; Mr. Christopher Heath, London; Mr. J. R. Wallace, Bengal; Mr. Barr, Ontario; Dr. Gilbart Smith, London; Mr. Whitney, London; Mr. Cullimore, London; Mr. Rowlandson, Durham; Mr. Jas. Allen, Bollington; Messrs. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Clinical Lecture
ON
CASES OF ANOMALOUS RHEUMATIC FEVER.

BY C. HANDFIELD JONES, M.B. CANTAB., F.R.S.,
PHYSICIAN TO ST. MARY'S HOSPITAL.

(Concluded from p. 857.)

CASE 2. *Articular rheumatism, probably pericarditis; anasarca; heart's sounds very weak; pulse for a time very irregular; much tremor of hands, delirium, grave bronchitis; recurrence of rheumatism in hands; heart's sounds again distinct; recovery.*—E. C——, aged thirty-five, labourer, married; admitted Dec. 29th, 1880. He had been unwell about seven weeks; up to that time always had good general health. Works from 8 A.M. to 1 P.M. at a public house. For the first two weeks he felt very much out of sorts, then had violent pains in all his joints for about a week, "which made him nearly raving mad." About a month ago his feet, legs, and belly began to swell, and about the same time his breathing began to get bad, but he does not seem to have had great dyspnœa; he was always able to talk fairly well. No cough, no expectoration. At present has no pain anywhere, but a feeling ot general oppression; his "heart beats like two hammers." Has been in bed at home about five weeks; was unable to lie on either side; could only lie on his back. The lips are pallid, and the face especially. Legs pit slightly at the ankles and a little above. Urine acid, thick with lithates, contains no albumen; quantity less than it was two months ago. Resonance in both fronts not quite satisfactory; air, however, enters well in right front; in the third left space the breath sound is defective, but without any distinct râle. Back tolerably but not fully resonant; breathing defective in left lung, especially at lower two-thirds, the inspiration being short and harsh. In right back the air enters tolerably well in upper half; but in the lower the entry of air is defective, and muco-crepitant râles are heard at the base. Skin of præcordia has been severely blistered. Heart's impulse weak, diffused, distinctly perceptible to the finger at the epigastrium; faintly seen at right nipple-line, but not felt. Dulness area extends up to about level of third space, as far as the right edge of sternum, and to left for half an inch beyond right nipple-line. Heart's sounds at mid-sternum are weak and distant, and very much so at vertical nipple-line in left fifth space; no murmurs. Pulse about 108, and very weak, intermission of its beats cannot well be ascertained, as the tendons twitch very much. Lower belly dull on both sides, but not at hypogastrium. Liver dulness extends from fourth space to a little below level of navel. Broth diet, beef-tea, milk. Bicarbonate of soda, one drachm; water, two ounces; effervescing citric acid, half a drachm, to be taken three times a day.—31st: Says he did not sleep for more than half an hour, is restless, something "bewilders him"; no cough at all; heart does not hammer as it did; appetite fair; tongue moist, but thickly coated, brownish-yellow in middle; bowels open four times in night after medicine, and twice this morning; both hands are excessively tremulous. Pulse irregular—96 to 112. Right radial described by clerk as wriggling with an undulatory movement, assuming an S-shape. One observer detected a high pitched systolic musical murmur at left of mid-sternum. Ordered bromide of potassium, ten grains; chloral, ten grains; tincture of opium, ten minims; water, one ounce, at bedtime. Tincture of digitalis, ten minims; carbonate of ammonia, four grains; infusion of cascarilla, one ounce; three times a day.

Jan. 1st, 1881: Slept fairly well; complains most of his ribs being sore. Bowels opened each time he had a dose of the effervescing mixture; stools very loose. It has not been given more than once or twice a day since the 31st, and is now omitted altogether. Takes food well. Tongue moist, with some yellow dryish fur. Belly measures over navel thirty-five inches and three-quarters. Both pulses very irregular as to rhythm and size of beat. Respiration 32, even, quiet; rhythm of heart irregular; dulness area as before. Tracing unequal; secondary rises very high; hyperdicrotism marked in some beats, absent in others. Heart sounds are markedly weak, but less distant; much sonorous râle in both fronts and backs; air enters very imperfectly, especially at lower backs; no dulness. He sits up well in bed. To take six ounces of port wine.—3rd: Last two nights has had: camphor, one grain; extract of hyoscyamus, five grains, in two pills. Has slept a good deal, but has been and still is now rambling and talking loudly. Pulse 120, fairly regular. Breath short; has to lie high; expectorates more mucus, a little red in one part, blackish in another. Respiration 46; lower ribs collapse during inspiration; very weak entry of air in all left back and in all right. To take decoction of senega, one ounce; oxymel of squills, one drachm; ipecacuanha wine, ten minims, every three hours.—4th: Is now and has been the whole night through constantly talking; once got out of bed; is often quite delirious; yet he is evidently now half rational, or soon becomes so. He shows me himself his expectoration; says that he has not had a wink of sleep all night, and that he has been talking about home and business matters. Says also that his back aches, and his side aches, and that he aches all over. Hands and forearms so tremulous I could not take a tracing. Pulse 120, regular, weak; face pale; takes food well. Entry of air in both backs weak, and crepitations are heard everywhere.—5th: Says he feels much better to-day. Slept a good deal in night with one grain of opium twice. Pulse 110, of fair force; expectoration very scanty; right back dull at lower fourth; left not so much; air enters left lung pretty freely, except at lower third, where a good deal of crepitation is heard; in right back air does not enter so well, and crepitations are heard everywhere; respiration 36; tongue coated and dry; bowels not open; enjoys food; pupils of good size; still talks and rambles a great deal.—7th: Bowels freely open; has had two good nights; is much more quiet; talks much less; sputa of deep orange tint; air enters lungs better, but still defectively, especially at right posterior base, where there is dulness; crepitations heard extensively in both backs. Pulse 110, weak; lies down well. Has one grain of opium every night; one grain of calomel to-night; bacon, egg.—8th: A little rambling in sleep, but nothing like what it was; legs still anasarcous, but less so. Pulse 130; heart's sounds still very weak; tongue cleaner; backs resonant except lower right; air is heard at upper backs entering tolerably well, but the lower one goes the worse the entry gets; much râle is heard at lower thirds in both, most in right; inspiratory and expiratory dry râle in both fronts; third left space rather dull; second resonant; hands steadier; his fingers appear distorted, much as in chronic rheumatism, but he says this has only come on since he has been ill; urine in good quantity, red, clear; no cardiac murmur. Iodine liniment to præcordia; half a grain of calomel and half a grain of opium three times a day; omit mixture.—11th: Yesterday had pretty copious vomiting twice, none since; last night good; feels very weak; gums at edges getting red and tumid. Pulse 108, of good volume, compressible, regular; heart's sounds weak, but distinct, second especially; urine deposits lithates copiously; is in good quantity. Takes food very well, enjoyed roast meat to-day. Lungs in much the same state; right radial curves and elongates at each beat; tongue moist, cleaner.—13th: Seems better; no dyspnœa; lies down well. Pulse 113, regular. Scarce any expectoration. Respiration 30. Heart sounds more distinct. Legs much less œdematous. Breathing much freer in upper backs, numerous crepitations in lower. Urine clear, of medium colour, alkaline. Calomel omitted. Tincture of squills, twenty minims; tincture of digitalis, ten minims; acetate of ammonia mixture, one ounce; three times a day.—15th: Pulse 110, regular, sharp, of fair force. Sleeps and eats well; wants to get up. No expectoration. Weak entry of air, with half moist crepitations in both backs; a deep inspiration does not improve breathing much; respiration 25. Ordinary diet.—20th: Yesterday weather severe, pulse excited, 117; apex beat felt at vertical nipple-line, fifth space. Saccharated carbonate of iron, one scruple daily.—22nd: At xiphoid and apex sounds are of a cantering rhythm, no murmur, no apex beat or impulse felt anywhere.—26th: Pulse very irregular two days ago; a beat was frequently too weak to reach radial. Pulse still very unequal and irregular. Anasarca gone from lower limbs some time ago. Tracing not so irregular as pulse appears. Sounds of heart pretty distinct at vertical nipple-line, fifth space; first rather weak. Ordered four grains of carbonate of ammonia, and one ounce of infusion of cascarilla, three times a day.

Feb. 2nd: Rheumatism recurred in both hands and left shoulder yesterday, but nowhere else. Pulse regular, jerky, 110. Wrists and shoulder blistered; ordered three doses of salicylate.—7th: Pulse quite regular; temperature nearly normal. Is doing well. A whining sound of cardiac rhythm is heard at left edge of the sternum during all the respiratory period, except about end of expiration. Sounds of heart more distinct, first of a murmurish quality at the apex, but not in the left side.—10th: Tracing tall, sharp-peaked; dicrotism late. He is up and dressed, and seems going on well, but his temperature is not yet normal. Good resonance in all left back; rather weak breathing at lower part; scarce any râles. Right lung in nearly the same state.—17th: Sounds of heart much more distinct; has had a small blister at horizontal nipple-line, on account of some uneasiness in that situation. Repeat it. The whining bruit continues, but is not constant; does not accompany the natural sounds. —21st: Pulse 100, standing; respiration 20. He then went down a long flight of stairs and up again; pulse immediately after 120; respiration 18. He feels very well, except a little soreness at the left chest.—24th: Going out. Heart sounds very plainly heard through all his clothes. Taking citrate of iron and quinine, ten grains.

March 3rd: Came to hospital looking pale and not so well. Heart sounds were well heard, but not quite pure; there was no murmur with them, but some of the whining sound. Dulness area extended from left edge of sternum to about vertical nipple-line. Third left space resonant. Complains of soreness in the left chest.

April 11th: Came to the hospital; was much better; taking strychnia and pernitrate of iron.

CASE 3. *Rheumatic fever (second attack); failure of salicylate; mitral systolic murmur; morbilloid eruption; epistaxis; hyperpyrexia; cool packs; iced baths; delirium; death.*—A D——, aged nineteen, porter, admitted Sept. 30th, 1878. He had rheumatic fever eight years previously, was laid up all the winter. Three weeks ago he had symptoms threatening another attack, shiverings, and much perspiration; these passed off. On Sept. 29th he was seized in the afternoon with pains in limbs and stiffness. In the morning he was so much worse that he could not dress, and was admitted to hospital in the afternoon. He cannot assign any cause for the attack. An uncle is the only relative subject to rheumatism. One ounce of salicylate of soda mixture every hour for six times.

Oct. 1st: Is a fair, robust-looking youth; skin hot and moist; has sweated profusely all night; tongue rather furred; great pain in both knees and wrists, which are swollen and very tender; heart's apex beats in fifth space in vertical nipple-line; a systolic bruit heard at apex and in carotids; vessels of neck pulsate much. Pulse 120, jerky, soft, empty between beats, especially when hand is raised; urine clear, sp. gr. 1018, no albumen. Salicylate mixture repeated, but temperature rose at night to 103·5°.—2nd: Symptoms not improved; skin very hot and moist. Pulse 106; systolic bruit at base of heart and in carotids followed by sharp second sound. Salicylate repeated.—3rd: Night very restless; he could not sleep; had no delirium; great pain in left knee and right hip, and in both shoulders; heart's apex beats outside vertical nipple-line; loud blowing systolic murmur at apex, also at base and in neck, where there is great impulse; epistaxis occurred at noon to about two drachms.—4th: Sweating very profusely; reaction of sweat neutral; urine is markedly acid; pain is very much less; had not much sleep in night; kept waking up in a fright and feeling giddy; tracing sharp-peaked, with a small shoulder in fall; dicrotic notch on basal line; extensive morbilloid rash on chest and abdomen; began early this morning to take thirty grains of acetate of potassium, twenty grains of bicarbonate of potash, and one drachm of tincture of oranges, in an ounce of water, every three hours.—5th: Says he is much worse; seems very weak and distressed; has had epistaxis to some ounces this morning; is subject to epistaxis; pulse very soft, 120; rash more developed on trunk; it consists chiefly of dull red patches, with little points of commencing sudamina. To have six ounces of port and two ounces of brandy.—7th: Was very ill all yesterday; five grains of quinine were given every two hours after 10 A.M. until evening; had about three hours sleep after a large mustard and linseed-meal poultice to chest; to-day is very restless; tongue coated in middle; pulse of good force, 112; perspiring much less; urine on 6th very acid, sweat neutral; at present skin pungently hot; third left space rather dull, second resonant; sounds of heart very weak, hardly any first sound at mid-sternum; bowels open three times this morning; is very restless now (4 P.M.), face pale, and aspect distressed. Temperature 105·4°. Has just been sick after a dose of quinine; respiration this morning 56; takes food fairly; not much articular affection. A cool pack was administered about 6 P.M. for an hour.—8th: Looks better to-day; had some sleep after first pack; a second to-day about 10 A.M. for two hours; legs and feet feel stiff and numb, has noise in his ears and deafness; is taking nourishment well; no delirium; pulse 115, large and of good force. An iced bath was given at 6.30 P.M. The temperature before was over 105° (probably); the water was at 80°; it was found difficult to reduce its temperature, though a large amount of ice was put in. At 6.45 P.M. the patient's temperature was 104·8°; at 7 P.M., 103·4°; at 7.15 P.M., 101·4°; he was then removed to bed, and at 7.25 P.M. the temperature was 98·6°. It rose again, however, quickly; at 9.45 P.M. it was 103°, and later 104·6°.—9th: He was quiet during the night, but somewhat delirious; had not much sleep; appearance better; less pallid than it was; expectorates some muco-pus; pain in joints less; can raise a cup to his mouth; seems to want sleep; tongue cleaner, moist; bowels open three times in twenty-four hours; takes nourishment well; pulse 108, of good force and volume. Between 4 and 5 P.M. he had another iced bath. The temperature fell very rapidly; in twenty minutes it fell from 104·2° to 97·4°. He was then taken out; his extremities were cold. Fifteen grains of Dover's powder and an ounce of acetate of ammonia mixture were given after the bath. He was very restless and delirious during the night. The quinine mixture was resumed.—10th: Is very much worse, extremities are cold and bluish, lips and face leaden; is very restless, continually changing his position; respiration deep and sighing, 46 per minute; pulse weak, 132; skin generally of a dusky hue; died at 12.30 in the afternoon.

All in rectum. Pack at 5.45 P.M.

Post-mortem.—Rigor mortis and hypostasis well marked. A small abscess over the sternal end of the left clavicle. About three ounces of blood-stained serum in each pleura. Right lung congested posteriorly; areas of collapse scattered through the same part, disappearing on inflation. The posterior parts present the early stage of brown induration. Weight of right lung 26 oz., of left 21 oz. Left lung in same condition as right, but in a much less degree. Bronchi filled with frothy mucus; their mucous membrane congested. Pulmonary artery full of dark blood. Pleuræ free from adhesions. The pericardium contained about an ounce of turbid serum. Some flakes of lymph over auricle and roots of great vessels. The heart weighed 22 oz., and contained 16 oz. of clot.; it was a well-marked "cor bovinum." Cardiac veins distended; arteries normal. Muscular substance on left side ¾ in. thick, pale and soft; right side ⅜ in. thick. Left auricle filled with soft, black coagulum; cavity dilated. Mitral valve showed old thickening, and subendocardial capillary hæmorrhages at attached border; orifice 5¾ in.; ventricle extremely dilated (left), filled with pale and dark clot, the former recent; aortic valves thickened at lines of contact and free borders, incompetent; orifice 3¼ in. Right auricle gorged with mixed coagulum and dilated; valves healthy. Tricuspid orifice 5 in.; insufficiency less marked than mitral. Pulmonary artery normal; orifice 3½ in. Vena cava superior full of dark blood. A patch of atheroma at commencement of aorta. Liver weighed 65 oz.; soft, fatty; centres of lobules congested; old infarcts in middle of right lobe. Spleen weighed 7 oz., soft. Kidneys 7½ oz. each; capsules peel off readily; pyramids pale and very firm.

Remarks.—All these cases were undoubtedly instances of rheumatic fever, though the phenomena they exhibited were by no means identical. This is a first point to note. "Varium et mutabile semper fœmina," says the poet. The physician may apply the epithet to disease. Not that we are to overstrain the statement, and think of disease merely as the individual sufferer presents it to us, overlooking or unheeding all that there may be common to numberless instances. But we must be prepared to meet with great variations, especially if we ply our craft under widely differing circumstances. In the first two cases the disorder receded and quitted the joints for a considerable time, during which internal organs were severely affected, and then returned for a short time to its original site as the malady declined. In Case 3 there was also marked recession of the articular symptoms when the general condition became worse, but the fatal close prevented their recurrence. Look, therefore, suspiciously on the disappearance of articular affection in rheumatic fever, unless it be attended with improvement in other respects. Pericarditis with effusion occurred in Cases 1 and 2, but the effusion was not copious. In Case 2 weakness of the heart's sounds and irregularity of the pulse were marked features. Had the physical signs indicated very large effusion, the pressure thus made on the walls of the heart would have been a sufficient cause for these phenomena, but as this was not the case it seems to me most probable that myocarditis existed. This may have either directly impaired the contractility of the heart's muscular tissue, or, as Dr. Walshe suggests (p. 260), might have enfeebled the action of the organ by influencing (inhibitorily) its nerves. In Case 1 the cardiac dulness was at one time more extensive than it ever was in Case 2, but the heart's sounds were never so weakened, nor the pulse so irregular. The anasarca of the lower limbs in Case 2, according to the evidence, was certainly of cardiac origin, and so affords additional proof of the enfeebled state of the heart. In Cases 1 and 2 delirium was a rather prominent phenomenon, especially during the earlier part of their stay in the hospital. It was tolerably acute, but not violent, and not much trouble was experienced in keeping the patients in bed. If you refer to some cases recorded in my work at pp. 169-171 you will see how very much the quality of delirium in retrocedent rheumatic fever may differ in different instances, and how much the treatment may have to be modified in consequence. The fits of restlessness and thirst which occurred in Case 1 may be regarded as of the nature of delirium. I take much the same view of the tremor of the hands and arms in Case 2, which for some time was so remarkable. The same disordered action of the cells of the intellectual centre which conditionated delirium might well in the motor centres give rise to an analogous derangement. In one familiar instance the two disorders coincide, and we have delirium tremens. Both Cases 1 and 2 had pulmonary catarrh to a serious extent, which for some time enhanced the peril considerably, especially in the latter, as the weather at the time was severely cold. The minute bronchi, if not the alveoli, were involved, and the patients might easily have succumbed from œdema of the lung. This catarrh was associated in Case 1 with an analogous intestinal disorder producing diarrhœa, and in both sites I believe resulted from the operation of the rheumatic virus, or influence, whatever that may be. Another interesting phenomenon, perhaps allied to the preceding, was the morbilloid eruption which was so marked in Cases 1 and 2. Trousseau designates such eruptions as "exanthèmes sudoraux," and thinks that they are chiefly produced by heat external or internal. Sometimes they resemble scarlatinal eruption more than that of measles, and may even be mistaken for the rash of typhus. They may occur in influenzal catarrh as well as in rheumatism, and may be very evident when pulse and temperature are normal. I have known the rashes create great and quite unnecessary alarm.

Hyperpyrexia was a prominent symptom in Cases 1 and 3, while in Case 2 it was contrastingly absent, the temperature only reaching 104°, and the average of the first fifteen days at night being only 101·4°, whereas in Case 1 the average of the first ten days (P.M.) was 103·3° and in Case 3 104·1°. We must admit, if we believe that there is a heat-regulating centre—as I assuredly do,—that this ganglion was very much more affected in the two latter cases than in the former. Just as the intellectual centres or the motor centres suffered from the morbid cause, so I conceive did the temperature-ruling centre. In many conditions of this kind the weakest part, that which has least stability, or power, or resistance, which is most vulnerable, suffers most, and the symptoms, the evident phenomena, are shaped accordingly. To check the hyperpyrexia cold baths were employed, ten of which were administered in Case 1 from Dec. 28th, 10 P.M., to Jan. 1st, 12 P.M. Their general effect was decidedly beneficial, though it often was very brief, the temperature quickly regaining its former height. Several of the later baths, especially the last, were of short duration, as they were not well borne; the last was followed by too much prostration to make a repetition desirable, and sponging was substituted. The subjoined table exhibits pretty clearly the effects of the baths on the temperature.

After the tenth bath the temperature was only once above 103° for twenty-four hours. On January 3rd (twenty-six hours after the last bath) it reached 104·8° at 2 A.M., and was only two-tenths lower at 4 A.M.; it then fell, and did not reach 104° again for twenty-four hours. After 4 A.M. Jan. 4th it sank, and remained below 104° and mostly below 103° for 116 hours; then marked 104° at 2, 4, and 6 A.M. of the 9th, again fell and remained at or but little above the normal for eighteen hours. At midnight of the 9th it ran up to 105°, and in spite of sponging did not fall materially for ten hours, marking 104·8°, 102·6°, 105°, 104°, and 104·6° at two-hour intervals. This, however, was the last gust of the storm, if we except one reading of 104° on Jan. 18th at 4 P.M., and one of 103·2° on Feb. 6th at 2 A.M. These brief recurrences of fever during an apyretic period appear to me very interesting, and can scarcely be accounted for except on the view that the heat-regulating centre at these times suffered a transitory paresis. Similar occurrences are met with in various morbid states. After Jan. 20th the bihoral observations were discontinued, and only five, four, or three taken in each twenty-four hours. During all this period, extending to March 17th, the temperature was normal, or nearly so. In Case 3 the baths were employed too late; they should have been commenced on the evening of the 5th, when the temperature reached 105°, and should have been repeated whenever it rose above 103°. The packs were insufficient for the wants of the patient.

The other remedies which we employed with the view of reducing fever—viz., salicylate and quinine—had no good result. The former produced much diarrhœa, and the latter on the last occasion when it was given in pretty full dose caused a rigor, with vomiting and purging. It is true that the doses of quinine were much less than those recommended by some high authorities—Jurgensen for instance; but such experience as I have had of the antipyretic action of quinine in acute non-malarious disease has not been favourable. It has lowered the temperature for a short time, but has otherwise seemed rather injurious. Dr. G. Smith, however, has seen much better results.[1]

Besides controlling pyrexia our efforts were mainly directed to maintain the force of the heart, to support the general strength, and to procure sleep. In carrying out these aims digitalis and opium were of real efficacy. Perhaps, however, the favourable issue of the malady was determined chiefly by the good behaviour of the stomach, which stood its ground bravely when most other organs were more or less disordered. I am often tempted to modify the apophthegm, *Φυσεως αντιπραττουσης κενεα παντα*, by substituting *Γαστερος* for the first word. You will surely find it a part of wisdom to make much of the stomach, and sedulously to avoid giving it offence. In Case 2 digitalis and opium and the expectorants served us well, and so, also, I think, did small doses of calomel three times a day. In Case 3 I am much disposed to think opium should have been used more freely. Judiciously employed, it certainly sustains failing nerve-power. The bedsore in Case 1, which threatened at one time to perforate the spinal canal, was dealt with successfully by keeping the lad lying on his face, and by applying carbolic lotion under tenax.

---

ON HOSPITALS:

THEIR MANAGEMENT, CONSTRUCTION, AND ARRANGEMENTS IN RELATION TO THE SUCCESSFUL TREATMENT OF DISEASE, WITH REMARKS ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS.

By FREDERIC J. MOUAT, M.D., F.R.C.S.,

FORMERLY PROFESSOR OF MEDICINE, CLINICAL MEDICINE, AND MEDICAL JURISPRUDENCE IN THE MEDICAL COLLEGE OF CALCUTTA, AND FIRST PHYSICIAN OF THE HOSPITAL ATTACHED TO THE COLLEGE; DEPUTY INSPECTOR-GENERAL OF HOSPITALS (RETIRED), ETC.

GENERAL INTRODUCTION.

SINCE the institutions devoted to the relief of suffering from disease and accidents have ceased to possess an exclusively ecclesiastical character, and become what they now are, and long have been, part and parcel of the general practice of charity and benevolence, in their purest forms, hospitals, with special reference to the successful treatment of those admitted within their walls, have scarcely kept pace in their construction and management, with the advance of civilisation in other branches of social economy. The present conditions of life in all civilised communities impose a strain upon mind and body by day and by night which is extremely difficult to bear, without serious risk of premature decay and death. The ever-increasing dangers to life and limb from the continuous and progressive multiplication of mechanical contrivances to supplement and supplant manual labour, and to annihilate time and space, have imported into Surgery fresh forms of accidents and injuries, and new pathological states resulting therefrom, which tax the highest resources of the science and art of the surgeon, to contend with and counteract. The gravitation of rural populations to urban centres, the result of new conditions of society, has caused the aggregation of human beings upon areas insufficient to maintain them in health and strength, without the aid of complex artificial contrivances. These conditions, with the insanitary surroundings inseparable from them, especially among the poor and improvident, coupled with the vices which are largely the outcome of undue pressure of population upon space and the means of subsistence, have become important factors in changing the form and character of many diseases, more especially those of the inflammatory and zymotic classes. This state again demands the employment of the most advanced means which scientific progress has placed at the command of the physician, to deal with successfully. All the above conditions, with a multitude of collateral circumstances intimately connected with them, invest hospitals with even greater interest and importance now, than they have ever previously possessed. Not only are they "Nature's schools where pupils are taught her ways in diseases and casualties, and the effects of the application of the means of relief," but they are emphatically the only places in which all the phases and varieties of sickness, whether of new or of old types, can be studied in a strictly scientific manner. The administration of the active principles of curative substances when separated from the inert or injurious matters with which they are combined in their natural state; the proper employment of anæsthetic and antiseptic agents; the skilled use of all new physical and mechanical contrivances for the detection, treatment, and removal of disease and its consequences, in circumstances where they can be subjected to the strictest observation and control; and, above all, the pursuit of pathological inquiry in the manner absolutely necessary for the advancement of science, are among the most important uses of hospitals.

The present, again, is an exceptionally appropriate time for the consideration of the question in all its bearings. An International Congress will shortly be held in this great metropolis, and probably collect a larger assemblage of medical men than has ever before been gathered together in London, from all parts of the world. Those to whom our institutions are at present unknown, and many to whom they are familiar, will doubtless visit them and contrast our methods of managing matters, with the prevailing practice in their own countries. It is much, therefore, to be regretted that in the questionable multiplication of sections and embarrassing accumulation of questions for discussion, most of them having no international bearings, room has not been found for that of the construction and management of hospitals, and a uniform general system of record of sickness and mortality for the hospitals of all countries. Great doubts, apparently on good grounds, exist among ourselves as to the advantages and disadvantages of large hospitals as compared with small; as to the real causes of the persistent unhealthiness of many of those institutions, both new and old, whether dependent on structural or other conditions; and as to the best means of securing all the conditions necessary to minimise the risk to life, of those who seek admission or are taken to them. There is by no means universal consensus on this and many similar questions, connected with hospitals. It would, therefore, have been invaluable to obtain upon them the views of the eminent practical workers in kindred institutions in every part of the world, after personal examination of all that we have to show them. Some nations have advanced beyond us in the matter, as I shall endeavour to show anon; and I still hope, in spite of the regrettable omission which I hold to have been committed, that their representatives will, on their return to their several homes, place their impressions on record in a form that will be valuable to us as warnings or examples.

The primary function of hospitals is the successful treatment of diseases and accidents, in the strictest relation to the interests and advantages of the sick and stricken individually. To this all other relations, scientific and administrative, must be absolutely subordinated, in spite of the widespread popular belief to the contrary, particularly as respects clinical hospitals, or hospitals forming part of medical schools. What, then, are the cardinal conditions to be observed in the construction, management, and distribution of hospitals to fit them for their special purposes in all the important relations in which they stand to the public, and to the profession most immediately concerned in their efficiency? It was truly said by one of our most eminent surgeons, Sir William Blizard, nearly a century since, that "the value of medical science in every walk of life, independently of its application in preventing and curing disease, should be seriously considered. All men are indebted to the discoverers and cultivators of natural truths for some share of their useful knowledge, and of the felicity they enjoy. Many, therefore, are the objects, interesting to society, that present themselves in contemplating the professional concerns of a hospital, and, as in commercial and other affairs of life, they will be best understood by men who have most devoted their time and attention to the subject. Everything liberal may be expected where charity is the governing principle of action, and where the good done bears proportion to the degree of knowledge exercised. Purity of motive, sincerity of attention in the surgeons, will not then be doubted. It may not, however, be improper to observe that their credit and interest are involved in all the proceedings of a hospital; for its prosperity is their elevation, its depression their loss and regret."

To consider, then, this important question correctly it seems to me to be desirable to group hospitals roughly into certain classes, and then to discuss in as much detail as may be necessary to their right understanding, the general attributes which are common to all, and those which are more or less restricted to the special purposes of each group, the successful treatment of disease being the cardinal condition, or *raison d'être*, of every such institution.

The simplest arrangement of all hospitals actually in existence is the following:—

1. Clinical hospitals, or hospitals attached to or forming parts of medical schools.
2. General hospitals, or those in which all classes of cases,

medical and surgical, are treated, with or without detached wards for infectious diseases, and parturition. In this group, I think, should be placed the great separate workhouse infirmaries, for reasons which will be mentioned when they come under review.

3. Special hospitals, such as fever and small-pox hospitals, lying-in hospitals, ophthalmic, skin, orthopædic, and other institutions devoted to specific purposes, usually indicated by their names.
4. Cottage hospitals.
5. Convalescent hospitals.

Each of the above groups, again, needs to be considered with reference both to institutions now in existence, and to the hospitals of the future. From them I have excluded dispensaries, free or provident, and all institutions which have no beds for taking in patients. These, with the out-patient departments of all hospitals, which might, I think, with advantage in many cases be separated from them, are most important complements of our hospital system, and, with the home treatment of such cases as are adapted for it, render it complete in organisation. But the latter scarcely fall within the scope or purpose of my contention.

The first step in the whole inquiry is to determine as far as possible what constitutes a healthy hospital, for this is universal in its application. In one of his classical reports, Mr. Simon has defined a healthy hospital to be "a hospital which does not *by any fault of its own* aggravate ever so little the recovery of persons who are properly its inmates, and this, the only right sense of the absolute word, governs the words comparative applications; so that when we compare them together with regard to their 'healthiness,' and call one of them the 'unhealthier' hospital, our meaning is that in this hospital, by means of some faults of its own, disease cannot be treated as successfully as in the other hospital; and the fault of its own, through which an 'unhealthy' hospital fails to attain the best results for its medical and surgical treatment, is of two kinds—either it is an *inherent fault*, as of site and construction; or else it is a *fault of keeping*, as dirtiness, or overcrowding, or neglect of ventilation."[1] Various attempts have been made to solve the question of the healthiness of hospitals as compared with each other, by contrasting the results chiefly of surgical practice, by an appeal to statistics. This doubtless is the true means of forming a correct judgment on all such questions as can be solved by the application of the numerical method. When figures are really exponents of facts, and are collected with mathematical accuracy, they "formulate the past, render the present fruitful, and prepare the future." But the terms of all comparisons, to be exact, must be identical, as dissimilar things cannot be compared in the strict sense of the word. Vital phenomena are so complex in their nature, whether in health or disease, and are influenced by so many collateral conditions, all of which require to be stated with minute care and accuracy, that the basis of a correct statistical comparison of the results of the practice of different hospitals, does not at present exist. Nowhere are the records of hospitals so kept as to afford more than a rough approximation to the truth, which has no pretension to scientific accuracy. In each and all of them some important factors are omitted, and in none that I am acquainted with, are any statistics of therapeutics or particular plans of treatment properly kept. That these latter exert an important influence in determining the results of medical and surgical treatment in hospitals, independent of all internal faults of their own, who can doubt who has watched and noted the changes in doctrine and practice of the present century, from the heroic bloodletting and *nimia cura medici* of its early part to the medicine expectante, homœopathy, hydropathy, and the important antiseptic surgery of our own times?

It is sufficient for my present purpose to state that, although we have no sound comparative data to guide us to a strictly logical conclusion, we have an abundance of testimony from figures which are of considerable value in themselves, in relation to many medical and surgical questions of great importance. Taken by themselves, they show that when varying proportions of mortality occur from the same classes of surgical procedure in similar cases, in the same or different localities, or where the death-rates from fever, inflammation, the process of parturition, and other general causes range to an extent indicative of greatly increased risks to life in some circumstances as contrasted with others, they point to the existence of something wrong. This *something wrong* demands the strictest investigation, and this is the real position in which the question now is. What, then, are the different factors which require to be taken into account in estimating the general conditions of healthiness in the sense used by Mr. Simon, or the reverse, of every hospital intended for the reception of the sick or disabled? As usual in all human affairs, the agencies to be considered are moral and material. The former refer to those employed in the control, direction, and management of hospitals; the latter relate to structural and other conditions which we know, or believe, to contribute to placing such institutions in the best possible state to fulfil their special purposes. It is manifest, and to this general rule hospitals form no exception, that the best and most perfect instruments may fail in careless or incompetent hands, whilst good work may be done with imperfect instruments by the more skilled and careful.

The question of the government and staff of hospitals is thus scarcely second in importance, to the principles which should be observed in their construction and arrangements.

For convenience of treatment I shall consider the whole subject under the following heads:—

1. The control and management of hospitals.
2. The construction and arrangements of hospitals, with descriptions of the most typical examples of recent hospitals.
3. The consideration of the several groups of hospitals.
4. The organisation of medical relief in the metropolis. In connexion with this will be published, on the 16th of July, a Map of Medical London, showing the exact position of every hospital of every class in it at the present time.

Lastly, the general conclusions to be deduced from the above.

(To be continued.)

ETIOLOGY AND CLINICAL BEARINGS OF THE GERM THEORY OF DISEASE.

BY DR. GEORGE HARLEY, F.R.S.

The Editor calls attention to the following:—

Note by the Author.—"Reformed speling: This paper is printed without encumbering its words with redundant, and consequently useles, duplicated consonants."

It must be understood that THE LANCET does not adopt the method, but simply complies with the request of Dr. Harley.

SINCE one may now venture to say, without much dread of contradiction, that science is begining rapidly to become the director of the general practitioner, as wel as the handmaiden of the consultant, and that in exact proportion as she apears in the sick-room does routine practice and empirical rule-of-thumb prescribing vanish, no apology need be ofered for my bringing under the notice of the profesion a few new facts which tend to elucidate the germ theory of disease. For it seems as if we were already hovering on the very brink of at least finding a truly philosophical explanation to what has hitherto been considered the totaly unacountable apearance of sporadic cases of contagious and infectious diseases, as wel as an equaly philosophic solution to the cause of the waves of epidemic afections which ever and anon sweep over and diseminate, in diferent forms, and at diferent times, diferent portions of the earth's surface during varying and hitherto inscrutable periods of time, and, after completely disapearing from a locality, reapearing in it again after longer or shorter intervals, and that, too, generaly in the same form, and oftentimes even under almost identicaly similar circumstances.

Moreover, I believe when the germ theory is properly and completely worked out, that it wil not only yield a philosophic clue to the suden outbreaks and equaly rapid cesation of epidemics, and the ocasional apearance of fatal sporadic examples of disease, but explain the *rationale* of the longer or shorter periods of incubation which folow upon the heels of infection and contagion, the causes of periodicity in the malarial group of afections, and lastly, the inexplicable phenomenon of the long intervals of quiescence in particular localities between the termination of one epidemic and the outbreak of another, which is so characteristic of virulent plague and Asiatic cholera, without necesitating the adoption of either the untenable theory of spontaneous generation or the equaly unsatisfactory one of the redevelopment of germs *de novo et ab initio.* Since the days of Spallanzani the spontaneous generation theory has been resuscitated on an average once in every twenty-five years. Twice within my own medical day have I seen the spontaneous generation theory revived, and on each ocasion it has found a suficient number of enthusiastic suporters to obtain for it an evanescent notoriety; but ultimately it has gradualy withered, decayed, and disapeared; again, no doubt, to be resuscitated—in some slightly modified form—by enthusiasts in suxeeding generations. If the germ theory of disease is to hold its ground at al it must sufice for the solution of the four folowing distinct pathological problems:—

---

[1] Sixth Report of the Medical Officer of the Privy Council, 1864. Pp. 39, 40.

(*a*) The cause of a distinct period of incubation folowing upon contagion and infection.

(*b*) The cause of paroxysmal and periodic malarial derangements.

(*c*) The cause of the suden outbreaks, and sometimes equaly suden cesation of epidemics.

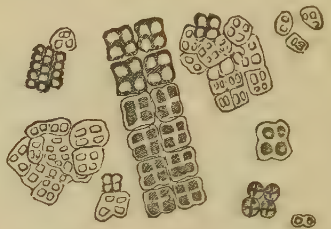
(*d*) The cause of long intervals of quiescence being noticeable between the termination of one virulent epidemic and the outbreak of another, equal in character and in virulence.

Such being the problems requiring to be satisfactorily solved by the suporters of the germ theory, I shal now ad my quota to the general stock of our as yet but very imperfect knowledge of the pathological action of germs in the animal economy, and do the best in my power in the short space I have here at my comand to aid their solution. Even should I suxeed in doing nothing more than giving my readers some new ideas for thought, I shal consider that I have not wasted their valuable time; for it may perchance hapen that the new ideas here sugested may lead to the unraveling of some of the knoty points abundantly scatered about in this as yet unworked-out field of pathological observation and speculation. In fact, I say this the more confidently from my believing that the main lode of the mine has not yet been struck upon; that merely pioneer shafts have been sunk, which, however, having already yielded rich samples of valuable ore, make one feel sanguine of raising profitable returns when once the main lode of the mine has been actualy reached.

Those who have taken suficient interest in the germ theory of disease to read al that has been recently writen upon the subject must be perfectly conscious that it has already not only aduced facts which have given an entirely new complexion to our ideas regarding the etiology of epidemics of both temperate and tropical zones, but even of the pathology of boils, absceses, erysipelas, gonorhœa, and chancre. So that it may safely be prophesied that as our knowledge of the life-history of epizootic and miasmatic poison germs becomes more extended our ideas of the nature of al diseases, without exception, wil materialy change. This I am sanguine enough to believe must of necesity be the case, for even within the last five years a clue has been aparently found in the writings of Pasteur, Lister, Billroth, Ewart, Buchner, Watson Cheyne, Ogston, Koch, Wolff, Klebs, Neisser, Obermeier, Recklinghausen, Bastian, Tyndall, Rindfleisch, Stromeyer, Letzerich, Birch-Hirschfeld, Waldeyer, Carter, Bell, Ballard, Greenfield, Sanderson, Taylor, Riess, Coze, Feltz, Frisch, Vogt, and Israel, to some of what have heretofore been considered the most obscure parts in the history of contagious and infectious diseases. These writers have in different ways shown, from direct observations made on the human subject, how typhoid fever can be distributed by contaminated water; how scarlet fever can be propagated by the milkman's can; how woolsorters' disease can be comunicated from a sack of horsehair, brought al the way, it may be, from the stepes of Russia. Nay, more, Obermeier has shown that a germ named "spirilum" is invariably present in the blood of patients sufering from relapsing fever (*Centralblt. Med. Wissensch.*, 1873, p. 145). Manson has shown that elephantiasis is due to the presence of a filaria in the bloodvesels. Lewis and Bancroft have stated that chyluria and lymph-scrotum depend on the existence of the same parasite in the lymphatics, and it has been long known that the eating of bread made of spured rye (a disease of the plant produced by a fungus) gives rise to fever and local inflamations ending in mortification of the parts so afected, be they the toes, the fingers, or the point of the nose.

It has equaly for at least more than a quarter of a century been known that a chronic form of gastritis, acompanied by frothy vomiting, is entirely due to the presence of a microscopic organism caled the sarcina ventriculi, which exerts its pathological powers by producing violent fermentation in the contents of the stomach, in which it multiplies to a suficient extent to give to the ejected maters a green apearance. One of the most careful experimenters of the present day again—Mons. Pasteur[1]—has clearly shown that he can give anthrax, Siberian catle-plague, to sheep by watering their food with disease germs. He has also equaly clearly demonstrated that "chicken-cholera" can be propagated by inoculating fowls with bacteroid disease germs. Again, the experiments of Dr. Vandyke Carter on the artificial introduction of the spirilum parasite into the subcutaneous tisues of animals, monkeys, &c., show that not only are marked febrile symptoms—after a period of incubation—the result; but anatomical lesions in some respects resembling those met with in contagious jaundice—namely, "congestion of the mucous membrane of the stomach with minute petechiæ about the midle of the viscus, while both the liver and the spleen are congested" (Medical and Chirurgical Society's Transactions, vol. lxiii., p. 140). Here from spirili we have not only, as Dr. Carter remarks, a congested liver, but blood extravasation, exactly analogous to what ocurs in the preliminary stage of the black vomit and tary ejections, not alone met with in contagious jaundice, but in acute atrophy of the liver, as wel as in the malarial jaundice of the tropics;[2] while splenic fever has equaly been shown, by experiments on animals, to be the product of a germ caled bacilus anthracis. Talamon says (in a comunication he made to the Société Anatomique de Paris, 1880-1) that by inoculating a specific bacilic form of organism into the mucous membrane of the mouth of animals (rabits, guinea-pigs, &c.) he obtained the formation of a false membrane, and an œdematous condition of the submucous conective tisue exactly analogous to what ocurs in diphtheria in the human being, and that the false membrane thus artificialy produced contained similar bacilar organisms to what ocur in true diphtheria. Aded to this the folowing paragraph in the *British Medical Journal* of Nov. 6th, 1880, also tends to throw light on the etiology of malarial as wel as of contagious jaundice.

FIG. 1.



"Dr. Lauchlan Aitken of Rome writes to us:—'The proof of the existence of a specific malarial germ has just received important confirmation. At the Italian Medical Congres held in September at Genoa, Dr. Marchiafava, asistant to the Profesor of Pathological Anatomy at Rome, anounced that he had found the bacilus malariæ in the blood of three patients during the cold stage of the malarial fever from which they sufered. Since that time twenty-four cases have been examined, with the result, in every instance, of showing the presence of the bacilus in the blood during the period of invasion, while the spores alone could be seen when the fever was at its height. The same careful observer, as long ago as last autumn, had found the rods and spores of the bacilus in the lymph, blood, spleen, and medulary cavities of bones at the post-mortem examinations of three persons who had died from pernicious fever, but no one had hitherto suxeeded in demonstrating the presence of the bacilus in the blood of living patients, owing to the specimens examined having been always taken during the hot stage of the fever. Profesor Perroncito of Turin (one of the leading mycologists of Italy) has repeated Dr. Marchiafava's observations in the Hospital of Vercelli, in Piedmont, which anualy receives about four thousand cases of malarial fever, though not of a pernicious type, from the surounding district, which is covered with ricefields. The result is that he, too, has found the bacilus, ocasionaly in large quantity, in the blood, during the cold stage of al the cases examined, and sometimes also in the last hours of the intermitent period. I saw, to-day, at the Santo Spirito Hospital, a specimen of blood within five minutes from the time when it had been taken, with al due precautions, from a patient just entering on the cold stage, which contained two or three bacili in al respects identical with those exhibited at Cambridge, got, it may be recolected, by the cultivation of some mud from near Selinunte, a very malarial port in Sicily. Observations are now to be made, both at Rome and Vercelli, acording to a comon programe drawn up by Profesor Tommasi Crudeli, of the blood of the spleen drawn of by aspiration through a hypodermic syringe during the last hours of the intermitent period, and also of the perspiration and urine during the stage of resolution. Profesor Tommasi Crudeli hopes that British practitioners, who have many oportunities, both in India and the Colonies, wil make similar researches, but cautions them that a good ilumination is esential, and that it is useles to work with les than a one-eighth-inch object-glas.' "

[1] Vide Compt. Rend., and Chemical News, 1880, 1881.

[2] The reason why, here and elsewhere, special reference is made in this paper to hepatic afections arises from the fact that it was originaly writen in the form of a chapter on the Etiology of Epidemic Jaundice in a new work entitled, Liver Diseases with and without Jaundice, which I purpose isuing in a few months, and it is only on acount of its containing much original mater, throwing considerable light on the germ theory of disease in general, that it is now being laid before the profesion in the pages of THE LANCET

With these preliminary remarks I shal now proceed to give a brief sumary of my views regarding this stil imperfectly understood question. In 1858-9, when the germ theory was begining to ocupy the atention of pathologists, and it was said that diphtheria was due to the fungus caled oidium albicans, growing in and upon the mucous membrane of the fauces, it ocured to me to test the mater experimentaly (see THE LANCET for Jan. and Feb. 1859) and while doing so I was led to make a series of physiological experiments with the expres view of ascertaining the folowing points :—

(*a*) If healthy vegetable microscopic fungi and their spores when introduced directly into the circulation of healthy living animals produce deleterious pathological results.

(*b*) If they do, to try to ascertain whether or no their pathological results were due to the mere mechanical presence of the fungi and their spores in the tisues and circulation, or to their posesing a special toxic action upon the animal system—acting, in fact, like true poisons; a poison being, as I define it, a substance which in minute quantity poseses the power of producing artificial disease, either alone, or artificial disease and death, by its action upon the nerves and other tisues of an otherwise healthy animal; poisons being either mineral, vegetable, or animal, and acting in one of two ways, either as dead chemical substances, or as living organisms—so-caled germ-parasites—which produce artificial disease in, and the death of, the animal they infest by virtue of their development and multiplication in its bloodvesels, lymphatics, and tisues.

(*c*) If, again, it were ascertained that living germs produce disease and death by specific toxic action, aparently in the same way as dead poisons do, to try to discover whether or no each individual species of germ posesed a deleterious specific something proper to its own organisation, or had merely axidentaly acquired poisonous properties from the soil in which it grew, and the materials upon which it chanced to have fed.

(*d*) If the severity of the pathological results folowing upon the introduction of living animal and vegetable organisms is in proportion to the abnormality of their source more than to their organisation.

(*e*) If animal germs are as deleterious to animal life as vegetable ones are.

(*f*) If the introduction of germ-spawn would be suficient to induce the same chain of pathological results as the introduction into the body of mature germs themselves.

(*g*) If physiological animal poisons, such as snake venom, act in the same way as pathological animal germs do.

These being the questions I set before myself for solution, and being already aware, from results I had previously obtained from the injection of putrid fluids, such as blood and milk, into the circulation of healthy animals, that the deleterious efects of decomposing animal mater are like those produced by mineral poisons as materialy influenced by quantity as by quality, before atempting to draw any conclusions, I determined to regulate as corectly as posible the quantity of materials employed in each experiment, as wel as the extent of surface with which they were brought in contact. This was al the more necesary for me to do from my entertaining the belief that al the manifestations of healthy animal and vegetable life observable by us are, as I said in the debate which folowed the reading of Dr. Marcet's paper on Respiration at High Altitudes, at the Royal Society in February, 1881, nothing else than the chemico-physical results of the active progresive oxygenation of organic compounds; while I am further of opinion that al the varying forms of decomposition and putrefaction of animal and vegetable mater, though the result of a retrograde proces of oxygenation of organic mater, is acompanied by, and indispensably conected with, the development and multiplication of living organic and organised germs.

Moreover, believing as I do that there are both animal and vegetable disease micro-organisms—colectively named germs,—and perhaps even a third species ocupying the debatable land between the animal and vegetable kingdoms, al of which live and breathe[3] just as big animals and plants do, I selected for my experiments the folowing materials :—

a. Vegetable ferment germs, from German yeast. *b.* Vegetable fungi and fungi spores, from the surface of decomposing wheaten flour paste. *c.* Vegetable oidium albicans, from decomposing healthy gastric juice. *d.* Vegetable fungi and spores of fungi cultivated in an aqueous solution of decomposing muscle. *e.* Vegetable green fungi and spores of fungi grown on the scum of putrefying snake's intestines.—*f.* Animal ferment germs, Brownian granules, vibriones, &c., from putrid normal gastric juice. *g.* Animal ferment germs, Brownian granules, vibriones, &c., from macerating diseased bones. *h.* Animal heterogeneous micro-organisms, from foul-smeling disecting-room macerating-trough. *i.* Animal germ-spawn, obtained separated from mature organisms by filtration through thick white filter-paper. *j*, and lastly. Physiological animal poisons from cobras and puf-aders.

The experiments were conducted in the folowing wise, and, in order to enhance the comparative value of their results as near as posible, under precisely the same conditions. The animals used were adult healthy dogs and rats, and always operated upon at the same period of digestion. The materials employed were always suspended in distiled water, and slowly injected into either the jugular or femoral veins, or under the skin of the animal's back. The fungi taken from putrid solutions were carefuly washed with distiled water on a filter before being used. Some trifling variations made in the mode of experimenting wil be specialy aluded to in each report of the special experiment.

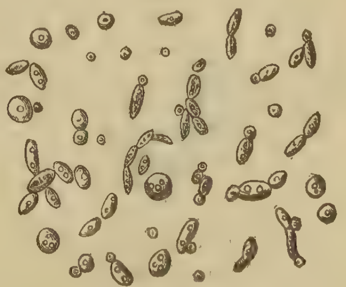
The order in which the experiments were conducted—both as regards the vegetable and animal micro-organisms—was first to take the normal, then the abnormal, begining with those suposed to be the most benign, ending with what was regarded as the most virulent.

Every experiment was repeated twice, and if the results obtained were not in both cases identical, it was repeated until I was satisfied that the result was trustworthy. I shal now give examples of each experiment, the results of which, if carefully read, speak for themselves.

Efects of Vegetable Germs Artificialy Introduced into the Bodies of Healthy Animals.

(A) Mixed with an ounce of distiled water a quantity of friable German yeast paste, Sacharomyces cerevisiæ, which, under the microscope, showed large spores of an average diameter of $\frac{1}{400}$ m.m., besides numerous Brownian granules in active movement, together with a few elongated cels,

FIG. 2.



Yeast plant.

---

[3] Hatton (Chemical Society's Journal, p. 247, May, 1881) found that bacteria absorb oxygen from the atmosphere, and give back carbonic acid just as large animals do, and the hoter the weather and the sunier the day the more active are their respiratory proceses.

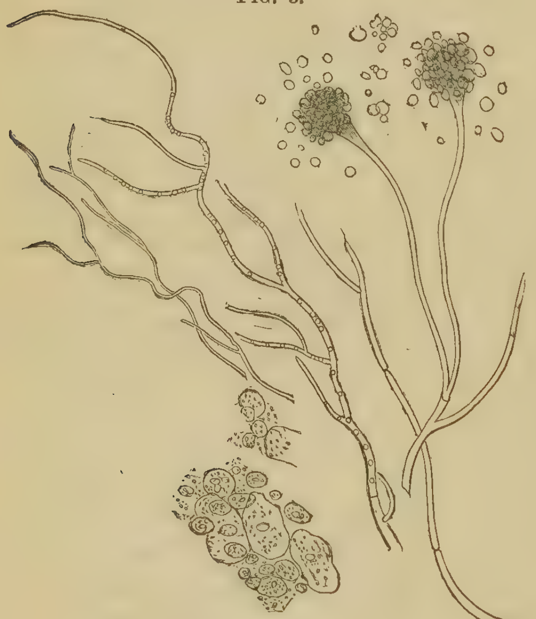
partly with granular contents, partly with one, two, and sometimes three distinct nuclei in them. Many of the spherical spores posesed also one and sometimes two nuclei. After brisk agitation, on standing for a minute or two, the distiled water stil retained in suspension enough of the yeast to give to it an opalescent milky apearance. This mixture was then slowly injected into the left jugular vein of a healthy dog. The result was absolutely *nil.* For neither imediately after the injection nor for seven days subsequently did the animal manifest one single pathological sign or symptom. As the animal refused either to die or become il on the eighth day it was kiled, and a careful post-mortem examination made.

The tisues when examined after death al apeared healthy. Its blood ran into beautiful normal rols, and looked in every respect perfectly normal. Not a fungus filament nor a fungus spore was to be seen in it, which proved that they had been destroyed in, and eliminated from, the circulation. But what destroyed them, or whether their elimination took place by the kidneys, lungs, or skin, there was no evidence to show.

(B) The next point was to ascertain if other kinds of fungi and fungi spores were equaly harmles as yeast ferment when introduced into the circulation of a healthy animal; and with the view of ascertaining this point the folowing experiment was made. A quantity of the green flowering fungus which grows so luxuriantly on old wheaten flour paste was colected, and wel washed with distiled water; after which as much of it was aded to a fresh quantity of distiled water as it could suspend for a few minutes, after brisk agitation with a glas rod, and an ounce of the mixture slowly injected into the right femoral vein of a healthy, ful-sized English terier dog. No imediate efects were observed; but on the folowing morning it looked drowsy and listles. This efect soon, however, pased of, for it was, to al apearance, perfectly wel the next morning, and so remained.

(C) Being satisfied that these kinds of microscopic fungi, grown in decomposing vegetable soil, produced no deleterious efects on healthy animals, I proceeded a step further, and tried to ascertain if the same kinds of fungi grown in decomposing animal soil were equaly inocuous to animal life.

Fig. 3.



Oidium albicans.

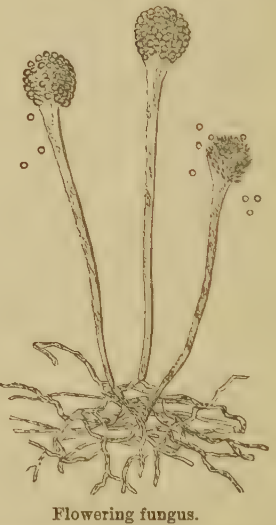
A quantity of oidium albicans, which I had artificialy reared in normal gastric juice, obtained from a dog's stomach through a fistulous opening, after being washed was aded to, and suspended in distiled water in the maner already described; but as it was rather lumpy it was strained through a muslin cloth before being injected, and to make sure that both filaments and spores went through the cloth a drop of it was examined under the microscope. Finding that the strained water was loaded both with spores and filaments, an ounce of it was slowly injected into the jugular vein of a healthy, nearly ful-grown, mongrel pointer dog. It produced no imediate efect, but on the folowing day the animal semed out of sorts. It began to get beter on the next, and three days after the injection was made it had perfectly recovered.

Having now, as I thought, learned suficient of the efects of injecting into the circulation of healthy animals what might be caled non-deleterious vegetable fungi and fungi spores, it was deemed advisable to advance at once a step further, from the simple to the complex, and consequently I

(D) proceeded to inject into the right femoral vein of a healthy dog the same quantity (as near as could be guesed) of the filaments and spores of an oidium albicans fungus, after having wel washed it with distiled water, artificialy cultivated in a putrid solution of human diseased muscle. Next day the animal apeared out of sorts, and continued so for several days, but by the end of a fortnight it was perfectly wel. Here be it observed more decided toxic efects were produced than in the preceding case. This I believe was due to the fungus employed having been grown in a more deleterious kind of putrid animal fluid, and its probably having imbibed some of the liquid's putrescent ingredients. On pushing this mode of experimenting a stage further, the folowing stil more marked toxic symptoms were obtained:

(E) I took a quantity of microscopic green fungi in ful bloom from the scum on the surface of water in a dish containing the putrefying intestines of a cobra (the animal that kiled his keeper at the Zoological Gardens), and to make sure, as far as was posible, that none of the animal germs in the scum were left adhering to the external surface of the fungi, washed them in seven diferent quantities of pure distiled water; then aded them to a fresh quantity of distiled water, which on brisk agitation became of quite a green color, and a puf-bal-like odor. An ounce of this saturated water was now injected into the right jugular vein of the same terier dog as was employed in experiment (B), which apeared to be in buoyant health. This was done on a Saturday, and when the dog's kenel was next visited on Monday morning, which was not for forty-four hours, it was found not only dead, but quite stif, with rigor mortis, and its tongue hanging out of its mouth. The left side of the heart was contracted upon a smal, but not firm blood-clot, in which there was no separation of red from white coagulum visible. The thoracic organs apeared to be more than usualy ful of blood, and the thymus gland was decidedly congested. The trachea and the epiglotis also had their vesels congested, and in half a dozen diferent places there were smal mustard-seed-sized extravasations of blood in their mucous membranes. In the duodenum, again, there were equaly signs of extravasation, and about five inches from the pylorus four ulcerations,

Fig. 4.



Flowering fungus.

---

[4] These figures of fungi are taken from the 2nd Edition of my "Histological Demonstrations" (Longman and Co.), in the Morbid Anatomy part of which wil be found figured several other kinds of the fungi and algæ which attack the human body.

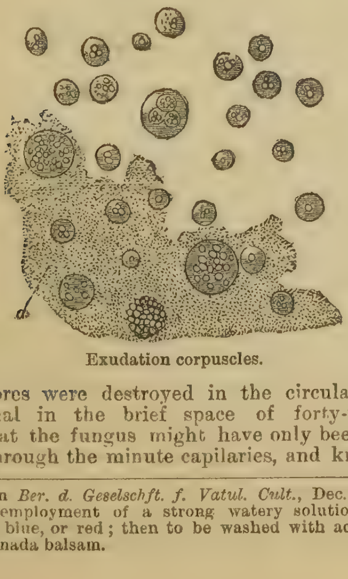
in a row, of the size of threepenny and fourpenny pieces, looking in some respects like abrasions. Blood extravasations are, as is wel known, comon in al putrid fevers. Dr. Greenfield, in a lecture on Anthrax published in THE LANCET in the early part of 1881, states that he noticed similar echymotic or hæmorhagic conditions in the carcases of catle which had become infected with anthrax from drinking infected water, and that the echymoses were invariably found to be due to thrombosis of the vesels by means of the germs caled "bacili," the bacili being frequently also found in the capilaries of the lungs and spleen. While in the internal anthrax known as woolsorters' disease Dr. Greenfield noticed a similar state of maters as I discovered to exist in some of my dogs operated upon—namely, that there were echymoses and hæmorhages along the course of the trachea. He even in some cases found extensive hæmorhages in the bronchial glands, and in al bacili were detected. The thymus gland in my experiment was decidedly inflamed.

The blood of this dog was found coagulated both in the heart and large vesels, and when examined with the microscope nothing was noticed abnormal about it, except that the wals of the red corpuscles on the adition of water broke down with unusual speed, and alowed the escape of their contents. Bacteria and bacili, being unknown organisms in those days, were of course unlooked for, but had any germs been visible without special preparation, it is probable they would not have escaped detection. However, the fact of none having been seen by me does not prove that none were present; for germs may be present in abundance in blood, and yet escape observation even when looked for, unles a special means is adopted to render them visible. Thus Koch tels us that in the blood of a mouse which he poisoned by injecting under its skin putrefying blood, he could detect no organisms by the ordinary means of microscopic investigation; whereas after using aniline dye[5] with a good ilumination he found lots of bacili, even within the white corpuscles.

With regard to the condition of the blood in this dog, it may be mentioned that in the first place, before the injection was made, half an ounce of blood was withdrawn from the jugular vein, and to it was aded some of the same fungi and sporules as were injected. After being wel mixed together, the mixture of blood and fungi was put on one side, in order to observe what would ocur in it, and to compare the result with blood which had been impregnated with the fungi and sporules in the living circulation of the animal.

On the blood that had the fungus aded to it after its removal from the body being examined, abundance of both fungus filaments and fungus spores was found in it, whereas, strange to say, not a single fungus filament, and only a very few fungus spores, could be detected in the blood taken from the dog after death; which proved not only that the spores did not develop, but even that the fungus filaments and the spores were destroyed in the circulation of the living animal in the brief space of forty-four hours. Thinking that the fungus might have only been arested in its pasage through the minute capilaries, and knowing that if so the easiest plan to detect fungi filaments and spores in the capilaries would be in those of the lungs, diferent portions of the lung-tisue were carefuly examined under the microscope by myself and several of my pupils, but not a vestige of fungus filament or fungus spore was anywhere to be met with. Nevertheles, the blood had been very materialy afected by the introduction of the fungus into the living circulation, for it was found by a carefuly-conducted experiment in my gas laboratory at University Colege that it had lost its power of becoming scarlet on being oxygenated by exposure to atmospheric air. It even only slowly oxygenated when put into a receiver with pure oxygen. In the second place, it contained an imense number of white blood-corpuscles. In the third place, it contained a number of large, pale, *nucleated* cels, identical in morphological character with what are known to morbid anatomists as exudation corpuscles, which showed beautiful nuclei on the adition of acetic acid.

FIG. 5.



Exudation corpuscles.

This experiment, on being repeated, did not yield such striking results. Yet, as it was in every other respect identical, I came to the conclusion that the soil the fungus grows in, and the food it lives upon, has a material influence on its constitution and properties, for I consider that the gentle and repeated washings to which the fungi had been subjected were suficient to remove from their surface al the toxic animal micro-organisms of the fluid in which they grew; certainly, at least, not to leave behind adhering to the filaments and spores suficient of them to have produced death in a healthy animal within forty hours after their introduction into the body,—the adoption of which idea, the belief in the later theory would, of course, necesitate.

From the results of these experiments on vegetable organisms the folowing conclusions were drawn:—

(*a*) That certain kinds of vegetable germs are not deleterious — even when introduced into the circulation — to animal life.

(*b*) That certain kinds of vegetable spores can neither develop nor survive in the circulating blood of a healthy animal.

(*c*) A fungus which may have no toxic properties when grown in one soil, may acquire toxic properties suficient to be deleterious to animal life when grown in another.

(*d*) Certain kinds of fungus spores and filaments, when they produce pathological changes in the animal body, do so by virtue of their inducing chemical changes in the blood, and not merely by mechanicaly interfering with the vital proceses.

(*e*) That the healthy animal organism poseses the power of destroying and eliminating certain kinds of living microscopic spores and filaments of fungi from the circulation.

Some of these conclusions have in a measure been curiously borne out by the results of subsequent experiments made by Continental observers on the inoculation of animals with tubercle. Tuberculous inoculation produced tuberculous deposits, but the inoculation of calves' brains, and other equaly benign animal substances, produced nothing but trivial temporary local iritation, the foreign materials introduced being rapidly eliminated from the healthy organism. While my opinion regarding the fungi receiving poisonous properties from the soil in which they grow is confirmed by Dr. George Thin having found (Royal Society's Proceedings, March 3rd, 1881) that bacteria germs take up from the maters among which they grow even the minute solid particles through their wals.

Having finished, for the time being, with vegetable organisms, I next turned my atention to the discovery of the efects that might arise from the injecting of minute animal organisms into the circulation of healthy animals, which subject shal be considered in the next chapter.

BRISTOL ROYAL INFIRMARY.—A most successful appeal has recently been made in Bristol in aid of an old debt on the Bristol Royal Infirmary, of £10,200. The movement was commenced by a promise of £1000 by Mr. Dod of that city, on condition that the remaining £9200 was raised within three months. Mr. Charles D. Cave, the president, immediately set to work, and a public meeting was convened at the Guildhall, Bristol, on April 29th, presided over by the Mayor. Grave doubts were entertained as to the possibility of raising so large a sum within the specified time; but, by the energy and influence of Mr. Cave, in less than one month from the day of the meeting £9437 was obtained, thus securing Mr. Dod's offer with upwards of £200 to spare.

---

[5] Weigert, in *Ber. d. Geselschft. f. Vatul. Cult.*, Dec. 10th, 1878, recomends the employment of a strong watery solution of aniline-methyl, violet, blue, or red; then to be washed with acetic acid, and mounted in Canada balsam.

VACCINATION AND COW-POX INOCULATION.

By THOMAS NEWHAM, M.D.

THERE cannot be a fitter time for writing on the above subject than the present. Our old enemy, small-pox, is gaining ground in London, and occasionally spreading his arms so as to embrace our retired country districts. To us, who look to the statistics of the disease in our great towns with unfailing interest, the subject creates food for much thought. Is the spread of the disorder due to want of vaccination, imperfect vaccination, or imperfect isolation? The want of vaccination, or rather absence of vaccination, must necessarily prevail most in crowded cities. The opportunities for evasion of the law are much greater, and are resorted to by a class very much under the pernicious influence of the anti-vaccinationists. People migrate from street to street, and even into the country, with children utterly unprotected by vaccination. The increased facilities for migration, and the almost impossible task of perfect supervision, are thus great factors in absence of vaccination. It is easy to see that as these unprotected persons grow up they are simply so many firebrands for the spread of disease.

Of imperfect vaccination as a cause of the increase of small-pox I wish to speak with diffidence, and only from my own observation. To assert that this is a fertile source of the spread of small-pox is only to propound a truism. There are many reasons for such imperfection: obstinacy of parents, abstraction of lymph from the punctures by suction or other means, mistakes as to the age of lymph inserted, weakening the lymph by over-straining the source of supply, and the acceptance of vesicles which are neither true nor sufficient in their protective character. Every vaccinator must have seen instances of the crass stupidity of parents in endeavouring to remove the lymph from the arm. Suction by the mouth, poulticing with smashed turnips or carrots, and other devices, have been openly advised by anti-vaccinationists. The effect has been to seriously interfere with the formation and development of the vesicles, and to render them inoperative. The other causes of the non-efficiency of vaccination are dependent on the operator, arising from no wilful carelessness on his part, but very often by stress of circumstances. Take, for instance, the mistakes in the age of lymph. Children are inspected on the eighth day. There may be very fine vesicles full of lymph. The child may be healthy and strong. Other children are waiting to be vaccinated and the parents desirous to have this particular matter. The operator consents to their wishes with the result of a production of a crop of equally fine vesicles the next week. But there is "the little rift within the lute" denoted by too much areola, and too much lymph. Apparently effective, the vaccination is extremely limited in its protectiveness. The over-straining the source of supply may be due to over-demand and stress of circumstances. It cannot be too clearly understood that a great deal of the lymph standing in beads upon the vesicle is totally useless, and that the best cases must not be drawn upon to excess. That all these causes are at work, if not actually assisting in the spread of small-pox, yet forming only a weak barrier against its ravages, is amply proved by inspection in after years. During a long series of years I have had frequent opportunities of studying the effects of primary vaccination. It has occurred to me on several occasions of threatened spread of small-pox to be called upon for an opinion as to the advisability of revaccination. I have seen many instances where the marks showed very imperfect primary results. Very recently I have had unusual facilities for inspecting such results. The marks have been most varied in character. Some arms have presented only one mark—others, two and three. In some there have been only slight indication of puncture; while in others there have been large cicatrices—smooth, white, non-foveolated, unprotective. The whole of the inspections were of persons of adult age. I revaccinated the majority of the inspected persons with the result of producing in all the true Jennerian vesicle. In all the cases there was the usual malaise, the feverishness and the gradual and true rising of the pock indicative of perfect vaccination. I look upon this instance as fully supporting my theory, that one of the great aids to the diffusion of small-pox is imperfect vaccination. Whatever may be said by the opponents of the operation, one indubitable fact remains—that vaccination engenders confidence in the public mind, and great security is felt in its beneficent influence. It is our duty, therefore, to see that such confidence is not misplaced; and it is also our duty to insist upon revaccination whenever there is a chance or a fear of infection from small-pox. The readers of THE LANCET are quite conversant with the imperfections of all kinds of isolation. Communications of every sort are kept up with the outer world. If you attempt separation on a small scale, and impose stringent regulations, they are recklessly broken. Are we, then, to make no attempt in this direction? We are bound to do our best, but we shall never succeed in our efforts without revaccination. I have on several occasions stopped an epidemic of small-pox by establishing a cordon of vaccinated persons round the infected patient. However wise our precautions may be, revaccination is the only one absolutely reliable.

The remarks I shall have to make upon cow-pox inoculation are called forth by the letter of Dr. Battye in THE LANCET of April 9th. Dr. Battye says: "I hitherto understood that one who had had natural cow-pox was insusceptible to vaccine lymph from the human subject." The data upon which we have to form our opinion of the protective powers of natural cow-pox are extremely limited. In conjunction with, and separately from the late Mr. Ceely, I have examined numerous cases of so-called cow-pox in the cow and in the human subject. The investigations and writings of my late friend will always remain a monument of patient labour and scientific research, and, while I could never hope to imitate him, I did, at least, catch some of his enthusiasm. Mr. Ceely often declared to me that cases of natural cow-pox were extremely rare. He had often been sent for to see cases of supposed cow-pox, but had been disappointed at finding them spurious. My limited experience confirms his. Out of fifty or sixty investigations, I have only seen one true case, from which I vaccinated two children with perfect results. This was proved by their complete insusceptibility to subsequent vaccination from the human subject. So far, then, Dr. Battye's ideas are correct. Cows, however, are subject to eruptions upon the teats possessing many similar points to natural cow-pox. There is a supposed vesicle which is a bulla. This dries up and leaves a crust. The contained fluid is contagious. It affects the hands and arms of the milkers. The eruption and the attendant symptoms are violently inflammatory, with frequent axillary abscess. But it is not cow-pox, and used to be a frequent cause of over-confidence in the persons affected. I have vaccinated one or two cases of this sort from a child's arm, immediately after the eruption from the cow had declined, with the result of producing perfect vaccine vesicles. These facts go to prove that all accounts of natural cow-pox must be received with caution, and the more so as even the eruption which I have attempted to describe, not to mention the real disease, is rapidly dying out altogether in the vale of Aylesbury as well as in my own milk-producing district.

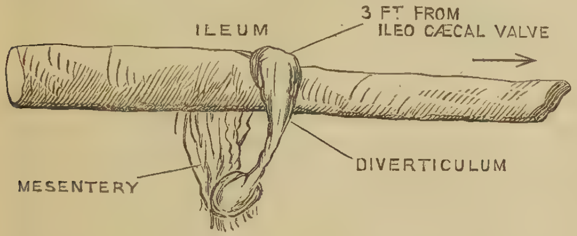
Winslow.

FATAL CASE OF INTESTINAL OBSTRUCTION FROM A DIVERTICULUM.

By J. SINCLAIR HOLDEN, M.D.

J. B——, aged thirty, a groom, had all his life suffered from irregularity of bowels, but was otherwise healthy. Lately he had an attack of diarrhœa, which stopped suddenly, and was immediately followed by vomiting and sharp colicky pains. In spite of treatment this continued, and in a few days the vomited matter was stercoraceous. On the fifth day I saw him in consultation with his medical attendant, Mr. Jones of Long Melford. There was scarcely any tympanites. In the region of the ileo-cæcal valve there was dulness, with gurgling and pain on pressure; the colon and lower bowel were empty, the temperature was normal, and the pulse 84. The vomiting continued, but was chiefly drink or food that was taken. The obstruction was evidently either at the valve or just above it, but as there were no inflammatory symptoms, we gave him five grains of calomel. This acted freely, and removed the pain and dulness from the right inguinal region, so that we had some hope that the obstruction had yielded; however the vomiting persisted, and the man died rather suddenly on the ninth day.

At a post-mortem examination made the following day, on tracing the ileum from the valve upwards, at a distance of about three feet, there was found a diverticulum about four inches long, extending from the upper surface of the ileum to the mesentery below, to which its end was attached.



Under the bridge thus formed there had passed a loop of ileum, a foot and a half long, almost black from intense congestion. The strangulation was incomplete, but as the congestion extended some distance higher, probably more gut had been involved during the man's illness.

The diverticulum was evidently congenital. The tube, where it sprang from the ileum, had an aperture of an inch; it then got narrow, and dilated into a cul-de-sac as large as a cherry. This was the only part adhering to the mesentery, to which it seemed naturally and firmly attached. The ileum abruptly narrowed from where the diverticulum branched off.[1]

I observe that a specimen of a similar diverticulum arising from exactly the same part of the ileum was shown at the Glasgow Pathological Society in May, 1875. Is this a coincidence, or do diverticula occur oftenest in this locality? If so, perhaps comparative anatomy could throw some light on the subject.

I shall be pleased to send the specimen to anyone who is specially interested in these peculiar appendages.

Sudbury, Suffolk.

INTERESTING SURGICAL CASES.

By J. D. T. RECKITT, L.R.C.P., L.R.C.S. EDIN., &c.,

LATELY HOUSE-SURGEON TO THE NEWARK HOSPITAL.

FRACTURE OF SKULL; EFFUSION OF CEREBRO-SPINAL FLUID BENEATH THE SCALP; ASPIRATION; RECOVERY.

ON Sept. 6th, 1880, J. W——, aged two years and a half, was knocked down by a passing cart, the wheel striking against his head. The child was insensible for several hours. Mr. Greenwood saw it at home, and ordered cold lotions and quiet. Two or three days after the mother noticed some squinting, and a swelling of the scalp as large as a hen's egg over the right parietal and temporal bones. Child partially conscious, but unable to walk or speak. The following week Mr. Greenwood let me see the case with him, and we could then make out a fracture of the parietal at its junction with the squamous portion of the temporal bone. It was decided to aspirate the tumour, which I accordingly did with the smallest needle, and drew off an ounce and a half of a light-yellow clear fluid. A pad of lint was applied, and firm pressure by a bandage, and this pressure kept up for a week, at the end of which time the swelling had disappeared and the squint too, but the loss of power over the legs remained. After the fluid had been drawn off the fractured part could be distinctly felt, and there was a hole at the squamo-parietal suture large enough to admit the tip of the index-finger.

Remarks.—From the existence of the squint prior to tapping the tumour, it might be inferred that we had to deal with a case of traumatic meningocele, the protrusion of the meninges through the separated bones and effusion of cerebro-spinal fluid within causing pressure upon the whole encephalon, and so producing the squint; at any rate, the fact remains that the squint disappeared with the fluid, which on careful testing was found to contain only a very slight amount of albumen. Two months after the accident paraplegia remained, and it is therefore certain the spine was run over or otherwise injured.

LITHOTOMY IN A CHILD AGED TWO YEARS AND EIGHT MONTHS.

William W——, aged two years and eight months, came under the care of my brother, Mr. Edward B. Reckitt, of Boston, Lincolnshire, on Feb. 4th, 1881, and through whose kindness I operated. The patient had shown the symptoms of calculus vesicæ for about sixteen months. He had lately emaciated very much, and the calls to micturate were very frequent and the suffering great. No blood ever voided with urine, but the prepuce was much elongated and reddened; no family history of stone.

Feb. 5th.—Under chloroform the bladder was sounded and stone detected.

6th.—Again under chloroform the left lateral operation was performed, and owing to the escape of urine on introducing the staff there was some little difficulty in getting a hold of the stone with the forceps, but with the scoop it was easily removed, and found as large as a chestnut and to be composed of lithic acid with an outer coating of phosphates. The child did well without any bad symptom, the wound at the end of a fortnight being healed.

Remarks.—That so large a stone should be found in the bladder of one so young surprised us. It is likely to have been formed congenitally.

Skegness.

CASE OF CÆSAREAN SECTION.

By JOHN H. GALTON, M.D. LOND.

M. L——, aged thirty-four, has had six children, all healthy labours. In 1873 was in Soho-square Hospital with misplacement of womb; was a widow for four years; married again in 1876; no pain or uterine discharge except leucorrhœa till after her second marriage. Soon after this, discharge, occasionally offensive and sometimes tinged with blood, came on, and for the last year she has had dull heavy pain, chiefly in the left side and back, sometimes darting down the thighs. She last menstruated on March 13th. On coition lately she has had bleeding. Labour-pains came on at 6 P.M. on Sept. 27th.

I saw her for the first time at 9 P.M. on that day. On examination I found the vaginal portion of the cervix absent, and the os surrounded by a hard nodulated mass of tissue with ulcerated surface, and bleeding slightly on pressure. There was no uterine pain during my stay, and, thinking that real labour had not commenced, I gave a dose of opium, hoping to defer interference till full term. At 11 A.M. on Sept. 28th I found that labour-pains had gone on regularly during the night, and were now at intervals of five minutes, with firm prolonged uterine contraction during the pain. The os was quite unchanged, and would not admit the tip of the finger. The uterus was enlarged to midway between the umbilicus and the ensiform cartilage, and the placental souffle was audible on the left side.

On consultation with my partner, Mr. Sidney Turner, it was decided to perform Cæsarean section, which was done at 11 A.M. with his assistance and that of Mr. Plimmer. The patient having been placed under the influence of chloroform an incision four inches long was made in the abdominal wall, in the linea alba, commencing half an inch below the umbilicus. The wall being very thin, the first puncture penetrated it and the uterine wall, and was followed by a gush of bloody fluid from the uterus, which spurted out strongly in a stream the size of a goosequill. This was stopped by finger pressure, and the rest of the incision continued down to the subperitoneal fat. The peritoneum was then divided throughout the length of the incision, on the fingers, and the uterus exposed. On enlarging the puncture already made it was found that the portion of the placenta lay immediately beneath the incision. The placenta was stripped off the uterus by the fingers, and the incision in the uterine wall prolonged downwards on a director. The head of the fœtus was first extracted, and the body and placenta easily followed. The fœtus was female, aged about six months and a half, born alive, but soon died. A portion of omentum and one coil of bowel at the upper part of the wound gave some trouble, but were kept back by moist warm flannel, and escape of liquor amnii and blood into the abdominal cavity prevented by firm pressure with the hand upon each side of the abdominal wall. About the average hæmorrhage of an ordinary confinement followed the extraction, and the uterus was cleared of clots three times by the hand. When the blood had ceased to well up from the uterine incision the edges of it appeared well in apposition, and the uterus was firmly contracted. It was decided to place no sutures in the uterine wall. Four silver-wire sutures were applied at intervals of an inch throughout the entire thickness of the abdominal wall, including the peritoneum, strips of strapping encircling the abdomen were placed between them, and a double pad of lint with a firm flannel bandage placed over the whole. One grain of opium was given, to be continued every four hours. At 11.30 P.M. the pulse was 130, feeble. Ordered milk in teaspoonful quantity, and ice to suck. At 4 30 P.M. pulse 108; temperature 101·6°; coughs occasionally with a little scream of pain. Exudation from wound slight. There is discharge of blood per vaginam. At 9.30 P.M. pulse 94; temperature 101·2°. Drew off a pint of urine with flexible catheter. Urine quite clear; no pain followed the emptying of the bladder. Abdomen very tympanitic, and distended above the bandage.

---

[1] During the treatment of the case the operation of gastrotomy was considered, but deferred, owing to the relief of the bowels. The probabilities are that if performed the narrow part of the diverticulum would have been mistaken for an adhesive band, which it resembled, and at once divided, so releasing the strangulated bowels; but instead of the result being a successful operation, fatal peritonitis would have been the sequence, from having opened a communication into the bowel through the severed diverticulum tube.

Sept. 29th: Has not slept. At 5 A.M. very restless, moaning; after that could take nothing. At 11 A.M. vomited curdled milk; asking for water; urine thick, about half a pint drawn off. Pulse 140; temperature 101°. Discontinued milk and took a teaspoonful of Brand's essence of beef every hour, with ice at 5 P.M. Pulse 120; temperature 101°. Still vomiting. At 10 P.M. pulse 110; temperature 101°. Urine not so thick as in the morning. Ordered one drachm of brandy every three hours, milk, and lime-water.—Sept. 30th: Vomited all night till 5 A.M., then vomiting ceased; at 5.30 A.M. had severe shivering. At 12.30 A.M. had profuse diarrhœa; at 11 A.M. pulse 118; temperature 98·4°; very little urine, thick and offensive. At 4 P.M. pulse 116; temperature 98·4°. At 10 P.M. pulse 121; temperature 100·4°; pulse feeble, but regular; vomiting continues, only kept down by brandy-and-water. Ordered one drachm of brandy every two hours; asks eagerly for ale; allowed to take a wineglassful.—Oct. 1st: At 9 A.M. pulseless; temperature 101°; says that she is suffering no pain. Died shortly afterwards.

Necropsy twenty-six hours after death.—The abdomen was much distended at the upper part; decomposition had commenced. The edges of the abdominal wound were adherent, except at the skin edge, and this was united at only one of the sutures. The intestines were largely distended and universally injected with greasy surface; no adhesions. One part of the omentum especially was in a sloughy state. A large quantity of bloody serum occupied the pelvis and abdominal cavity. The uterus was completely down in the pelvic cavity. There was not any attempt at adhesion of the edges of the wound. Its internal surface was ragged in the front, fundus, and left side, and through part of the ragged surface the line of incision passed. There were no clots or other contents. The os presented a nodulated, broken-down mass, through which the finger passed easily, and the cervix was thickened and infiltrated. Decomposition was too far advanced to admit of microscopical examination of the mass.

Remarks.—I have thought this case worthy of publication as from unsuccessful cases we may learn more than from more fortunate ones. By performing the operation we could only hope to save a few months of painful life, but we avoided the reproach of undelivered labour with a chance of prolonged life, and even in the unfortunate event gave a less painful mode of death. As to the use of antiseptics, we could have gained little by them in this case, as we had already a fetid ulcerating surface at the os, which we were bound to keep open, and could not treat by injection for fear of causing uterine distension and disturbing the healing of the uterine wound. The important question of uterine sutures is, so far as this case goes, answered decidedly in their favour. In a case in which the uterus acted as this did sutures of carbolised gut would certainly be useful, but the plan recommended by Dr. Barnes of applying the sutures through the uterine and abdominal walls is certainly contra-indicated.

ST. GEORGE'S HOSPITAL.

TWO CASES OF CATARACT.

(Under the care of Mr. BRUDENELL CARTER.)

FOR the following notes we are indebted to Mr. W. Adams Frost, F.R.C.S., assistant ophthalmic surgeon.

The following cases of cataract occurring in young adults present some unusual and interesting points.

CASE 1.—Caroline A——, aged seventeen, stated that she had good sight until fourteen days before admission.

On admission there was a uniform milky white opacity of the right lens, no reflex from fundus. The pupil was active, and there was good perception of light. In the left eye the opacity was less dense, and not uniform, the opaque portions being scattered throughout the lens, and having a woolly appearance, and being separated by comparatively clear lens substance. There was good reflex from fundus, but no details were visible. The right lens was removed by suction, no irritation followed the operation, and the pupil was quite clear. Three weeks after the first operation the left lens had become completely opaque, and was also removed by suction. Result, with correction, $V. = \frac{20}{50}$, and 1 Jaeger at 8 inches puzzled out in each eye. This patient had been attending the gynæcological department for some months for amenorrhœa. There was no history of any other illness.

CASE 2.—Clara K——, aged twenty-three, a Frenchwoman who had quite recently come to England and entered a religious institution. She was in an extremely depressed condition, and was said to suffer from headaches, but no history of any definite illness was obtained. The patient spoke no English, and a detailed history was therefore difficult to obtain, but both the patient and her friends stated positively that her sight was perfectly good three weeks previously.

When admitted there was general haziness of both lenses, with striæ of greater density. $V. = \frac{20}{70}$. The patient was anæmic, of sallow complexion, and complained of headache and nausea. Both capsules were freely lacerated, and the lenses broken up with two needles. The pupils were kept well dilated with atropine, and a week later there was no irritation. The patient's general condition, however, had not improved, and her depression had increased. The soft matter was now removed by suction in both eyes; a very small quantity, however, remained behind in the right eye. A good deal of irritation followed the operation, and in the right eye there was much pain and ciliary congestion; the pupil became blocked with lymph and soft lens matter. On the sixth day after the suction operation, Mr. Carter being unable to attend the hospital for a few days, Mr. Frost attempted an iridectomy, but, owing to the rotten condition of the iris, which was pushed forwards, no definite portion could be removed. Some of the contents of the anterior chamber were removed by suction, but the greater part was too thick to flow through the cannula. The congestion remained undiminished, the cornea became infiltrated with pus, and the globe shrank. In the left eye a considerable amount of irritation followed the suction operation; this subsided, leaving a pupil closed by lymph. The annual cleaning of the hospital necessitated the patient's removal from ward to ward, and as it was, under these circumstances, impossible to obtain nurses who could understand her, and her mental depression was very great, she was discharged, and further measures on the left eye were postponed. She was afterwards admitted into another hospital for an iridectomy with division of the layer of lymph in the left eye.

Remarks by MR. FROST.—These two cases are remarkable for the rapidity with which the cataracts progressed. In a matter of this kind, of course a patient's statement must be accepted with caution, but in the first case the consistent manner in which the patient and her friends gave the date of the onset leads me to believe in its accuracy, and in the second the good vision of the patient three weeks before her admission was proved. Lately I have seen several cases in young adults—females—in which flocculent-looking opacities in the lens have come on rapidly without any apparent changes in the choroid and vitreous; in most of them there was some disordered menstruation, but the number of cases is insufficient to determine whether this is accidental or not. I have, however, never seen a case in which the whole lens became opaque in so short a time. The second case is important as showing what disastrous results may follow a suction operation. Mr. Carter tells me that many years ago he lost an eye after this operation, and believing that he had discovered the cause in septic infection by the suction curette, he has since always disinfected the instrument immediately before use. This precaution was taken in this case, and the untoward result is probably to be attributed to the general condition of the patient. Unable to see and surrounded by strangers, with whom she was unable to exchange ideas, she sank into a moping and despondent condition, from which she could with difficulty be roused to take nourishment. The rapid onset of the cataracts points, no doubt, to malnutrition and low reparative power; but the happy result of the preceding case shows that this alone is insufficient to account for the course the case took. Possibly, if it had been possible to converse freely with the patient, some cause would have been discovered for her extremely depressed condition, which was at the time attributed to her loss of sight. The removal of lens matter by suction is an operation which is very frequently performed, but the above and the two cases recorded by Mr. Carter ("Diseases of the Eye," 1875, p. 365) are the only ones in which I am aware of any untoward results having followed when the operation has been properly performed.

NORTH STAFFORDSHIRE INFIRMARY.

THREE CASES OF EXCISION OF THE TONGUE, WITH REMARKS ON THE VARIOUS MODES OF REMOVING THE TONGUE.

(Under the care of Mr. WILLIAM DUNNETT SPANTON.)

THE best method of removing the tongue is still an open question, and appears a fair subject for discussion.

CASE 1.—Betsy D——, married, aged forty, residing in the country, was admitted in December, 1875. She was in a delicate state of health, had never been very strong, having had a family of eleven children quickly; the last child born ten months previously, and she had suckled the child most of the time. She was also suffering from more or less menorrhagia. She stated that about two months before she had first noticed a spot on the left side of the tongue like a blister. It was hard, and for many months gave no pain or trouble. At the end of a year an ulcer formed, which soon began to spread and cause pain. On examining the tongue the left side was found to be involved by a large excavated ulcer the size of a date, with hardened edges and bleeding on the slightest touch. In the right half was a nodule the size of a horse-bean, hard and tender. No enlargement of glands, speech much impaired, and there was a copious flow of muddy offensive saliva. No history of syphilis. She was under treatment for some time before admission, and was advised six months before to have the tongue removed, but some domestic circumstances caused the operation to be postponed until Dec. 23rd. Chloroform was then administered, and the patient was placed in the semi-recumbent posture, the mouth was kept open by a screw gag, a stout ligature passed through the tip of the tongue. The mucous membrane of the floor of the mouth was freely divided round the lower jaw with scissors, the genio-hyoglossus and hyoglossal muscles cut through, and separated more completely by the finger. A needle having previously been placed through the base of the tongue, the chain of an écraseur was passed round the base of the tongue as low down as possible, and behind the needle. The chain was made to cut through slowly, and apart from the bleeding caused by the division of the muscles there was no hæmorrhage. The surrounding tissues, after removal, were found soft and healthy feeling. The patient bore the operation well, after which she was enjoined not to attempt to speak. A very simple milk diet was ordered, and the mouth to be frequently washed out with a lotion of iodate of calcium (one grain to one ounce). On the following day she could swallow comfortably. There had been no hæmorrhage, and she had slept well. Pulse 80; temperature 98·6° F. On the 27th she was progressing well; the surface of the root of the tongue was beginning to suppurate; deglutition was easy and painless. Temperature 98° F. On Jan. 1st, 1876, four days after the operation, the wound looked healthy, but granulating with slight suppuration; profuse flow of saliva; no fetor. General health much improved, and the patient anxious to be up. From that time improvement was steadily progressive; she gained flesh, and when she returned home a month afterwards was in better health and far more comfortable than she had been for eighteen months before. She could speak rather more plainly than before the operation; the copious flow of saliva continued, but was free from any peculiar offensiveness. She attended from time to time, and kept very well until she had the misfortune to become pregnant again. This was the signal for a fresh inroad of disease in the submaxillary and cervical glands, from which, soon after she had given birth to her twelfth child, she died, about eighteen months after the operation.

CASE 2.—George W——, aged fifty, living at Hanley, was admitted in December, 1878. The family history was good. He had been a smoker, but not for some years. A brownish spot on the tongue was first observed nine months previously. This gradually increased and began to ulcerate three months afterwards. On admission the right half of the tongue was covered with a foul ulcer, surrounded by infiltrated tissue, which extended towards the left side beyond the middle line. It was hard and very painful, so much so that the patient had eaten no solid food for more than three months. The submaxillary glands were slightly enlarged and tender. There was profuse offensive salivary discharge. On December 12th, at the patient's urgent request, the tongue was removed under the influence of chloroform, in the same manner as in the case above described. There was no hæmorrhage except the bleeding caused by division of the floor of the mouth, which was very trifling.

On the 14th he was free from pain, and was able to sleep naturally for the first time for many weeks. On the 22nd the slough had separated and solid food was taken, and next day he left the infirmary, the surface of the wound looking healthy; glands still enlarged but not painful.

This patient was seen from time to time at his own home, and he continued comfortable until March, 1879, when the disease extended to the fauces, and the glands of the neck became extensively implicated, and at the end of May he died, about five months after operation. Although in this case the respite was not a long one, the patient repeatedly stated that he was thankful for the operation, so great was the relief he obtained. It was infinitely more tolerable even at the last to have a swollen neck and throat rather than a loathsome mass filling up his mouth.

CASE 3.—Edward H——, aged thirty-four, living at Mow Cop, was admitted on September 12th, 1879. The family history was good. He had been a smoker many years. There was no distinct history of syphilis, though he had thirteen years before had a slight sore, which healed quickly and was never followed by any secondary symptoms. He first noticed a hard nodule in the right side of the tongue three months before admission. This soon ulcerated and caused great pain. The tongue on admission was found ulcerated over the right side for the greater part of its extent, with a hardened base; and there was a hardened nodule on the left side of the tongue. The discharge was profuse and offensive. The glands of the neck were slightly enlarged and painful. A decayed tooth was removed, and a mixture was ordered to be taken three times a day containing fifteen grains of iodide of potassium with a drachm of the solution of perchloride of mercury in decoction of yellow bark. The mouth to be washed out frequently with a lotion of chlorate of potash.

On September 27th, this treatment having produced no beneficial effect, the tongue was removed. The operation was commenced by an incision made to the extent of about two inches and a half from the right angle of the mouth across the cheek, reaching to the edge of the masseter muscle. This procedure facilitated the subsequent steps of the operation, which were the same as in the two previous cases. The cheek wound was secured by two harelip pins and a figure-of-eight suture. There was no hæmorrhage beyond the usual small amount from the mucous membrane of the mouth at the time, but about four hours afterwards active hæmorrhage set in, causing the patient to lose about ten ounces of blood before it could be controlled. By reopening the cheek-wound the bleeding vessel was readily secured and ligatured, and there was no recurrence. The great use of the cheek-opening was then appreciated, for it would have been almost impossible to have secured the vessel without it.

On the 28th he had slept well and felt comfortable. The wound in the cheek which had been left open was reunited. The mouth was syringed out frequently with chlorate of potash lotion.

On Oct. 3rd the cheek wound was quite healed. The slough in mouth was separating. He had no pain, and took beef-tea and milk food freely.

On the 9th he spoke without pain; the slough had separated. The glands were smaller and painless.

On the 17th he returned home with the surface healed; glands were still slightly enlarged, and there was free discharge of saliva, but quite inoffensive.

On Nov. 23rd he was quite well; all swelling and pain gone.

Remarks by Mr. SPANTON.—These cases afford a fair illustration of the mode of treatment which I desire to advocate. But before entering into that question, a few remarks on the desirability of any operation at all in cases of this description may not be out of place. I have found among many surgeons a prejudice against any surgical interference. They will tell you that your patient is sure to die before long if you do operate, and under such painful conditions life is hardly worth prolonging. But what are the facts? Take an ordinary instance of cancer of the tongue, allowed to run its natural course uninfluenced by operation, and you will find in the decisive words of Mr. Erichsen ("Science and Art of Surgery," vol. ii., p. 427) that "nothing can exceed the misery of the patient's death, brought about as it is by pain, hæmorrhage, and starvation." And how long does such a frightful condition of misery last? It has been found, from a large number of statistics quoted in Mr. Clarke's work ("Diseases of the Tongue," p. 140), that the average duration of the disease, operated on or not, is fifty-seven weeks; the shortest, recorded at the Middlesex Hospital, being fourteen weeks, the longest extending over six years. With this distinction, however, that of those cases not operated on the average duration is only forty-two weeks, while that in which an operation has been resorted to is eighty-six weeks, the longest of these reaching to six years. Sir James Paget mentions an instance of longer immunity after operation.

In the first case I have related it is interesting to observe how pregnancy and suckling seemed to hasten the inroad of the disease, as is almost invariably the case; although theoretically one would have imagined that on the principle of starving the diseased parts, such conditions ought to have an opposite effect. It is, however, a matter of everyday observation to find pregnancy and its sequences especially powerful for evil in any devitalising disease. Having digressed so far, I come back to the question of treatment. If statistics prove anything, they assuredly go to show that in this affection a patient left alone has to look forward to possibly forty-two weeks of the most abject misery and suffering, which only those who have seen it can fairly appreciate; while on the other hand, if a complete operation be performed, our patient may fairly count on obtaining for some months at least immunity from suffering, and a life of comparative comfort. If recurrence of the disease should occur, it is usually in the glands or internal organs, and death takes place under infinitely less distressing conditions than would otherwise have been the case.

The gratitude expressed by those persons who have been relieved of the painful affection is a sufficient testimony, I think, to the desirability of removal. And inasmuch as we have to deal with a malignant, albeit localised disease, the obvious course is to remove it as speedily as possible; or, in the words of the late Mr. De Morgan, "to operate early" and "to operate thoroughly." Partial operations on the tongue, like imperfect operations for cancer elsewhere, have been almost uniformly unsatisfactory. Having decided on the removal of the organ, various methods offer themselves. My own conviction is that in this, as in most surgical procedures, the simplest measures are the best; and I cannot yet understand why it should be necessary to perform a complicated operation such as I will presently describe, when a far simpler one will answer the purpose equally well.

It would be interesting, if it were possible, to compare the results of the various procedures which have been adopted. That some are attended with a high rate of mortality I am quite convinced, and to this circumstance, in great measure, we may, I think, attribute the reluctance which many surgeons entertain in advising their patients to submit to excision.

The chief plans may be divided into four groups—

1. Removal through the mouth.
2. By an opening below the chin.
3. By dividing the lower jaw.
4. By combining tracheotomy with the third method.

We will take the last of these first. It was first practised in Germany, and has been advocated recently by Mr. Arthur Barker in a paper in THE LANCET, August 16th and 23rd, 1879. Mr. Barker there states that he has been struck by the number of deaths occurring after operations on the tongue from "septic pneumonia, with, in some instances, gangrene and abscess of the lung." This he attributes to the inhalation by the patient of the "*acrid fumes given off from a quantity of putrid material in the mouth, day after day, and night after night.*" (The italics are mine.) "Irritated at first," he says, "they become, under a continuance of the supply of the poison, intensely inflamed, and rapidly run through the several stages of pneumonia and gangrene." This opinion is supported by statistics quoted from Dr. Schläpfer, who has collected fifty cases recorded in various journals, with an entire mortality of 22 per cent., of which 12 per cent. were ascribed to various forms of septic lung mischief; also by some statistics of University College Hospital, which show that of twenty-one cases operated on for epithelioma of the tongue eight died, of whom five succumbed from lung complications, a rate of mortality of 23·8 per cent. from that cause alone.

Upon premisses such as these Mr. Barker has come to the conclusion that to obviate this very high (and I should hope unusual) death-rate, the rational method is to arrange the operative procedures in such a way that all chances of septic poisoning shall be excluded. And this is how he accomplishes it, as described in his own words:—"A Trendelenburg's cannula was inserted and inflated, and subsequently the tongue was removed, after division of the lip, jaw, and soft parts, down nearly to the hyoid bone. It was removed in two transverse sweeps of the knife, cutting half of the organ at a time, to allow of each lingual artery being ligatured separately. The next day the nostrils were plugged with cotton-wool, and the mouth closed and covered with a well-fitting pad. A silver drainage-tube was also adjusted in the floor of the mouth, over the end of which a rubber tube was fitted to carry off all discharge from the mouth into a basin of Condy's fluid at the bedside. He was then obliged to breathe by the tracheal opening, and by it alone. This was kept up for several days, until the stump of the tongue, &c., was comparatively clean. Later he was allowed to breathe by the nose alone (the mouth being kept still strictly closed and padded), and the tracheal wound was allowed to close. Finally, the pad was removed from the mouth." There was on two occasions some oozing, requiring the application of perchloride of iron, and there was a rise of temperature to 103°. This was considered to depend on an alveolar abscess, and relieved by extraction of some loose teeth. Convalescence was rendered tedious by exfoliation of two pieces of bone. In one case the drainage-tube was retained thirteen days.

Now, I should like to ask why at the time the patient had in his mouth a putrefying malignant sore, with poisonous breath and discharge, no pneumonic or septic symptoms occurred? And, further, why such symptoms should be looked for from a granulating surface, such as we usually have after removal of the tongue? Can anyone for a moment suppose that a fresh cut surface, and presumably a healthy one, could "exhale" such "irritating" or "acrid fumes" as would provoke pneumonia? I venture to assert that such a proposition is absurd. If "septic pneumonia" occurred, surely it would be in the way in which it usually arises after operation—i.e. from direct absorption of some morbid material into the blood. But why should such a condition be possible? Suppose the air of the ward to be in a proper condition, and you disinfect the wound in the mouth as it ought to be disinfected, and as in the cases I have recorded it was, what possibility can there be of any "acrid fumes," or even of any putrid material which could by any means lead to blood-poisoning, or lung-poisoning either?

It seems to me that in the operation Mr. Barker has proposed he has adopted, to begin with, a practice which has, I think, been properly designated "a relic of a barbarous state of surgery" ("On a Painless Method of Excising the whole Tongue," by Richard Barwell, F.R.C.S., THE LANCET, 1879, p. 549), and he has in addition to this further complicated it by opening the trachea, so that the patient incurs great risks, altogether foreign to the operation (in the shape of acute pneumonia, &c.); and also by adding to these an unnecessary meddling and paingiving method of carrying out the daily details of treatment. What better drainage-tube can you have than the open mouth? Drainage-tubes are not always models of perfection, according to Mr. Savory; and suppose an obstructed one in such a case as this, and what will happen? The patient will of course have to retain the very material which most of us are anxious to get away, and become very certainly poisoned. There is some truth in the assertion with regard to the offensive discharge no doubt; but this is, I believe, to be attributed not to the cut surface of the tongue, but to the needless compound fracture of jaw. There I think lies the secret. Let the bone alone, and adopting Mr. Barker's theory, you will need no such cumbrous and dangerous complications as tracheotomy and its multifarious accompaniments.

This brings me to consider the next method, No. 3. The plan of dividing the lower lip and symphysis menti devised by Sédillot, and improved upon by Syme, has been almost exclusively followed by the Scotch surgeons, and to this day a large number of operators adhere to it. The words of Mr. Barwell already quoted sufficiently express its character, though there may no doubt be some cases in which it may be required. In the majority of instances, however, it would appear as unwise as it is unnecessary to divide bone with all its attendant risks, when the object can be attained equally well without. The rate of mortality attending it is high, as we might expect, and the wound of bone must be held accountable I think, for many of the cases of septic lung mischief which are reported.

In Group 2, which I need not describe, we find many advocates, notably the late Mr. Nunneley, who was content with a small opening, through which he passed the écraseur, chain or wire; and although I cannot discover any statistics of his cases, they are said to have been mostly successful. Other surgeons have followed the same method in a more or less modified fashion. Mr. Barwell claims for his modification of it (*loc. cit.*) that it is painless, as he takes care in the earlier stages of it to divide the lingual-gustatory nerves. But I fail to perceive how the preliminary incision under the chin, and the passing through of threads and wire of the écraseur into the back of the mouth, can be effected without pain, and for the rest the same claim will apply to other methods in which the lingual-gustatory nerves are divided, be the preliminary proceedings what they may.

Now, we come to the first method I named, that of excising through the mouth with or without a buccal incision. Various ways of effecting this have been practised. The knife is, as Mr. Fairlie Clarke says, "the surest and the most expeditious," but he wisely refrains from adding, the safest. It necessitates abstention from an anæsthetic, and under any circumstances is liable to be attended with dangerous hæmorrhage. (It is, of course, understood that I am not now referring to partial operations on the tongue, in which probably the knife is the most useful.) Of the galvano-cautery I have had no experience. It is said to be very good and safe, although I have lately heard of a case operated on by this method which was followed by sharp hæmorrhage, necessitating ligature of the vessels. The old plan of ligature is now almost discarded, except for disease of the anterior portion; and it seems to me the sooner it is wholly discarded the better. It is painful, it is particularly disagreeable to the patient, and almost tempts septic mischief. Then there is the écraseur, for which we are indebted to Chassaignac. With this useful instrument the organ may be safely removed with little risk of hæmorrhage, and without difficulty. In the cases recorded I have described the manner in which I used it, and it need not be repeated here. I cannot conceive anything more simple or more satisfactory. There are, however, one or two points to which I desire to call attention. In my second case I experienced some difficulty owing to the large size of the patient's tongue. It seemed, when grasped by the écraseur, to fill the mouth, and interfere with breathing. At the same time it rendered difficult any attempt to feel or to see how the chain was working. As the result shows, this did not interfere with the success of the operation, but it led me to determine in my next case to lay open the cheek. We all know how very readily any cheek wound heals, so that there was nothing to deter one on that score. I found, as I had anticipated, that laying open the cheek enabled me to see the working of the chain during the whole time, gave room for passing in the fixing pins quite easily, and for the escape of any bleeding, &c.; and more than that, allowed free room for the patient to breathe. The operation was rendered very much easier for the operator, and I think safer for the patient. The proceeding is one I strongly recommend. The principal points are to divide the structures of the floor of the mouth freely, so as to be able to draw the tongue well forward without force; to work the écraseur chain from the front so as to divide the base as evenly as possible; to work the instrument slowly, and to administer an anæsthetic. With regard to after-treatment, it was very simple in the cases recorded. Frequent syringing or washing of the mouth with some antiseptic or disinfectant; frequent administration of milk and beef-tea, and keeping the mouth open as much as possible, but not permitting the patient to attempt to speak for a few days. In no case was there any symptom of irritation (the highest temperature was 99° F.), or the slightest approach to septic mischief, and the patients were in each instance up and about in a very few days. Would any of the other methods of treatment have yielded equally good results?

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Ununited Fracture of the Olecranon treated by Suture of the Bones.—Chromidrosis.—Stretching of Facial Nerve for Spasmodic Tic.—Excision of Breast in Intractable Eczema of the Nipple.

THE last meeting of this Society for the session was held on May 27th, J. Lister, Esq., F.R.S., President, in the chair.

Mr. MACCORMAC read notes of a case of Ununited Fracture of the Olecranon Process, in which Bony Union was obtained by Sutures of the Bones. The patient (who was exhibited) was a piano-tuner, twenty-six years of age, who four months before coming to St. Thomas's Hospital had fallen upon the right elbow, and sustained a fracture of the olecranon. When admitted the limb was wasted, especially the triceps; there was no power of active extension; the line of fracture ran across the base of the olecranon, the detached portion being separated by two inches, and fixed to the back of the humerus, the condyles of which could be felt in the gap, no uniting medium being perceptible. On Jan. 6th Mr. MacCormac made a vertical incision three inches long, exposing the fractured bone and the articulation. There was no trace of uniting material, the fractured surfaces were covered with smooth fibrous tissue, and adhesions existed between the detached process and the condyles, and also between the end of the humerus and ulna. These adhesions were dissected out, and the periosteum being reflected, a thin layer of bone was cut off with a chisel, and by means of two wire sutures through holes drilled in the bone the surfaces were brought into close apposition. The wires were twisted and cut off so as to project at the centre of the wound, which was afterwards closed with catgut sutures. The operation was performed antiseptically, the joint being washed out with carbolic solution (1 in 30) before closing the wound. The first dressing was made on the fifth day, when the wound was found to be united, except where the bone-sutures emerged, and these were removed in twenty-one days. In forty days the patient left the hospital with very good active movement at the elbow-joint, and apparently firm bony union at the seat of fracture. From first to last he had no pain or inconvenience. The wound healed without a drop of pus; the temperature occasionally rose to 99·8°; it was otherwise normal throughout. He has now perfect power of active extension. The arm cannot be made absolutely straight, but he is able to follow his trade as well as before.—Mr. LISTER believed he was the first to perform an operation of a similar nature many years ago in Edinburgh. The patient was an engineer in the prime of life, who had sustained a fracture of the olecranon. Mr. Lister exposed the ends of the fragments by a longitudinal incision; and after paring away the surfaces, drilled the fragments and tied them together by strong silver wire, using a single suture, which was more convenient than a double suture, for it remained in the line of incision. The result was, as in Mr. MacCormac's case, there was no inflammatory or constitutional disturbance. The man left with bony union and resumed his occupation. Since then, at King's College Hospital, he had similarly treated another case with like result. In neither was the upper fragment fixed to the humerus, as in Mr. MacCormac's case; nor was the separation between the fragments so wide. It was refreshing to hear antiseptic dressings spoken of as a matter of course; but he supposed few members of the Society would perform such an operation as the free opening of a joint without such antiseptic precautions as we possess, which afforded such security against complications.

Dr. T. COLCOTT FOX then read a paper founded on two cases of Chromidrosis, in which a deep blue-black pigment exuded upon the skin of the circumorbital region. The paper was illustrated by several beautiful drawings kindly lent the author by Dr. Foot, the President of the Pathological Society of Dublin. One case occurred in a girl aged eighteen years, a partial deaf-mute, but otherwise intelligent and of good physique, who presented herself amongst Dr. Donkin's out-patients at the Westminster Hospital, for the relief of a conspicuous and symmetrical black pigmentation of the eyelids and considerable portion of the adjoining cheeks, which caused great concern to the girl and her friends. The catamenia appeared first at the age of fifteen, and had never since been regular in time or quantity, and since that age the girl had suffered from general malaise, severe headache, and very marked habitual constipation. She was not an hysterical subject. The pigmentation was first noticed in September, 1880, on the lower lids, whence it gradually spread over the adjoining portions of the cheeks. Through the kindness of Drs. Sturges and Donkin she was placed under observation in the Westminster Hospital on three occasions, and it was found that the pigmentation varied considerably in amount and intensity, though present in some degree almost continuously. It was always less at the catamenial periods, but seemed to bear a direct relation to the very obstinate constipation, and was more intense and extended the longer the interval between the relief of the bowels. It was found on many occasions that whenever the latter became regular the pigmentation disappeared. As a proof of its genuine character Dr. Fox described the precautions taken to watch the case on one occasion for thirty-six hours, after the face had been thoroughly cleansed, but the pigmentation steadily returned. The urine was examined on several occasions for indican, which was found always to increase markedly in amount *pari passu* with the constipation and the exudation of pigment on the face. This fact, and the relation of the exudation to habitual constipation, are new points in connexion with the affection. Examination of the pigment showed it to present characters in all respects similar to those hitherto recorded in other cases by Charles Robin and others. The indian-ink-looking amorphous granules were found insoluble in almost all reagents, hot or cold, but displayed a deep blue colour when moistened with glycerine, and when dissolved in hot sulphuric acid firstly gave a beautiful purple hue, and, finally, a bistre tint. The pigment was evidently indigogenous. The second case was a girl of eighteen, sent to the author by Dr. Donkin. She was hysterical and phthisical, and suffered also from flatulent distension and constipation. The black powdery pigment afforded similar reactions to that in the first case, but the pigmentation was slighter and more fitful in appearance. In both cases any heat, emotion, &c., which determined the blood to the face, increased the pigmentation. Dr. Fox, in consideration of the fact that these were the first cases presented to a London Society with the exception of one shown by Sir Benjamin Brodie in 1845, entered into a short *résumé* of the subject and of other recorded cases, which are recorded in interesting monographs by Dr. Le Roy de Méricourt of Brest and Dr. Arthur Wynne Foot of Dublin, and insisted on the reality of the affection, which he challenged anyone to disprove. To the thirty-nine cases collected by Dr. Foot he added five others, making forty-four in all, six of them being in males and thirty-eight in females, at ages ranging between fifteen and fifty-seven years, and one a man aged twenty-two. The chief points discussed were the causation and the relation of the exudation to uterine troubles, general debility, and especially constipation; the influence of emotion, heat, &c., in increasing the pigmentation and the seat it usually occupies; the probability of the substance being exuded in a soluble form in the sweat rather than in the sebum, and its subsequent oxidation into a coloured pigment by contact with air; the varying shades of the colour (azure, deep blue, ochreous, black) of the pigment in different patients, and at different times in the same patient, the constant chemical and physical characters of the pigment, which prove it to be indigogenous and allied to similar products occurring occasionally in urine, pus, eczematous vesicles, milk, dropsical fluid, fæces, and vomit; and the arguments for and against malingering, showing, undoubtedly, that it is a real diseased condition. Lastly, Dr. Colcott Fox gave the results of the latest researches into the production of indican in the economy and its connexion with chromidrosis.—Dr. O'CONNOR asked whether there was any cutaneous hyperæsthesia or smarting, and whether the exudation was coloured from the first. The age of fifty-seven of one of Dr. Fox's patients was uncommon in these cases. In many cases uterine and other symptoms have appeared after the removal of the exuded material. He had seen one case in Dublin and one in London, and regarded the condition as one of steatorrhœa, of which there were varieties in the colour of the secretion. The black form of steatorrhœa was said to be hereditary. He asked, then, whether the sebaceous glands were affected, and thought it bore some relation to the condition of vitiligoidea, described by Addison and Gull.—Dr. CAVAFY had not the slightest doubt as to its being a genuine affection. The secretions of sweat and of urine had much in common, and he was glad that Dr. Fox had had the urine of these cases thoroughly examined for indican, with the result stated. The fact of the occurrence of this condition, together with obstinate constipation, favoured the view that the pigment was of the same nature as that in the urine—viz., indican, which occurs in excess in the urine during constipation. But indican appears in the urine under other conditions. Senator and Jaffe have found it in all chronic wasting diseases, in diabetes, in the later stages of carcinoma and in phthisis. It would be interesting to know if any of these coloured sweats occurred in phthisical people. By analogy similar explanations may be given for other coloured sweats. Red sweat may be due to an exudation analogous to hæmoglobinuria. Albumen has lately been observed in the sweat. Did Dr. Fox collect any of the fluid exuded, and, if so, did he find bacteria in it? For in one case in Germany chromogenous bacteria were found, and it was known that such chromogenous bacteria occurred in blue pus. The fact of emotion being followed by the outpouring of this blue sweat pointed to the occurrence of a local sweat centre, which can often be excited in a reflex way by the application of pungent substances to the tongue.—Mr. STARTIN asked if the coloured sweat occurred in other parts of the body. In a case under Dr. Payne, a woman aged forty, where there was uterine disease, there was coloured sweating over a limited area in each axilla. He suggested that a ferment was produced through the nervous influence, and that the indican became thereby oxidised.—Mr. LISTER, in his observations on blue milk, had thought it possible that the colour was due to the presence of bacteria, which were not themselves coloured; but in the present cases the colouration was related to nervous influences, and could hardly be supposed to be due to bacteria.—Dr. FOX, in reply, said that there was very little, if any, altered sensation in his cases. It was impossible to say whether the pigment was exuded from the sweat or from the sebaceous glands, but it contained no oily matter, which was evidence against its being a steatorrhœa, as Neligan supposed. No constitutional disturbance followed the removal of the pigment. In one of the cases Dr. Donkin found evidence of early phthisis. No bacteria were found in the pigment, and the effect of emotion in producing it was very marked. The indican rapidly became oxidised on exposure to air, and if its occurrence in sweat be admitted, there would be no difficulty in explaining the deposition of the pigment. The axillary secretion is naturally coloured.—Dr. O'CONNOR added, that in Sir B. Brodie's case Dr. Owen Rees found fatty matter in the deposit.

Mr. GODLEE read a short account of the progress of the case of Stretching of the Facial Nerve for Tic Spasmodique, related by himself and Dr. Allen Sturge early in the session. The patient on whom the operation was performed remained perfectly well till a month ago, then slight twitching of the orbicularis palpebrarum occurred in connexion with great mental worry; it was accompanied by some supraorbital neuralgia. A blister was applied above the eye and quinine was administered. The twitching has recurred once since that time again in connexion with a mental shock, but it has now disappeared again, the patient only having some stiffness about the eye, and difficulty in opening it when exposed to a cold wind. Another patient mentioned in the paper on whom Mr. Godlee had stretched first one and then the other facial nerve was also referred to, but as his case is not yet complete it was decided to postpone a detailed account of it till next session.—Dr. DOWSE said the recurrence of the affection bore out the experience of half a century in reference to nerve section in neuralgic and spasmodic tic; for invariably the affection has returned after a time. He had seen several such cases, and thought neither stretching nor division of nerves satisfactory. In cases of severe epileptiform neuralgia he had found the removal of exciting causes—e.g., carious teeth—to be the best treatment.—Mr. LISTER pointed out that nerve division and nerve stretching did not come under the same category. The remarkable fact was that the less violent measure was followed by the more permanent benefit; for recurrence of the affection invariably took place (sometimes very soon) after division, or even excision of a considerable length of nerve. But stretching in some cases—e.g., Nussbaum's—was actually curative. The case of Dr. Sturge and Mr. Godlee could hardly be said to be a failure, for both the slight recurrences of twitching had been dependent on derangement of health.—Mr. GODLEE, in reply, said that the patient had been treated by many physicians for four or five years without relief. The operation was not a serious one, and does not permanently lame the patient, who in this case has had one year at least of absolute comfort. The return of the twitching had depended on some nervous shock, and it was hoped that it would not be permanent. The relief obtained from the pains of ataxics by stretching the sciatic justified the operation, even if that relief were only temporary.

Mr. GEO. LAWSON exhibited a Breast, which he had removed on account of long-standing eczema of the nipple. In the reports of the Society for last year, after recording a case in which cancer had followed an intractable eczema of the nipple, he suggested that in cases of eczema of the nipple which have resisted for a length of time all treatment "the breast should be removed in anticipation of a disease which does not then exist." The case which he had now to relate was that of a lady who suffered from eczema of the nipple, which had resisted all treatment for over twelve months, and was extending. Feeling that the usual termination of such cases was diffused cancer, Mr. Lawson advised, and accordingly removed the breast. There was a red, scaly patch raised slightly above the level of the skin, and extending for about two inches around the nipple. The breast was examined by Dr. Thin, and he discovered cancer elements diffused throughout the organ. The preparation is now in the College of Surgeons' Museum.—Mr. LISTER thought the line of practice a serious one if meant to apply to all cases of eczema of the nipple. But he was not long ago consulted by a lady for eczema of the nipple, which he treated by local applications; but he heard afterwards that cancer had developed. At the same time he would hesitate about advising the removal of the whole breast in cases even of obstinate eczema of the nipple. In Mr. Lawson's case it did not appear that the breast was the seat of scirrhous cancer.—Mr. LAWSON said that he advocated excision of the breast in cases where the eczema of the nipple had resisted all treatment.

OBSTETRICAL SOCIETY OF LONDON.

AT the meeting on May 4th, 1881 (Dr. Matthews Duncan, President, in the chair),

Dr. GALABIN showed, for Dr. JOHN BASSETT, two specimens: (1) The Placenta from a Case of Triplets. On the fœtal side were attached three umbilical cords, and the remains of three sets of membranes, without any appearance of separation in the placenta. (2) A Fœtus with the Placenta adhering to the Cerebral Membranes. The vault of the skull was absent, and no brain substance was developed. The placenta, which was prævious, adhered to the cerebral membranes. These membranes contained some fluid. The child was delivered by version, and breathed for about an hour.

Dr. MEADOWS showed Pessaries made of the new material xylenite, a compound of paper and nitro-glycerine. It was more elastic than vulcanite, and could be more completely softened for moulding by boiling water.

Dr. GODSON exhibited a new apparatus for applying heat or cold to the surface of the body. It was known by the name of Leiter's Temperature Regulator, and consisted of a coil of pliable, metallic tubing, which could be adapted to different parts. A continuous stream of hot or cold water could be circulated through it. He thought it might be valuable in post-partum hæmorrhage.

Dr. CLEVELAND showed a cylindrical Fleshy Substance, about three inches by three-quarters of an inch. It had a remarkable resemblance to a uterus, having a mouth with lips at one end and a central canal. It was expelled with pains and slight hæmorrhage three days after delivery of a seven months' child. The lady, who had borne previously eight children, said that in her last two labours a similar substance, but rather larger, had been expelled on the third day.

The PRESIDENT narrated a case of Phlegmasia Dolens with Lymphatic Varix. He was disposed to support the view of Tilbury Fox and others, that phlegmasia dolens is due to venous and lymphatic inflammation and obstruction, and that, of these two, the lymphatic disease is the more important, especially as being probably present in every case, while the venous disease is occasionally absent. The case of white leg occurred in the downward progress of a characteristic case of cancer of the womb. During its presence there appeared lymph-angiectasis of a part of the skin of the thigh, and this disappeared as the phlegmasia disappeared. The part visibly affected was at the upper and outer part of the anterior surface of the left thigh, and constituted an oval or triangular area broader above than below, and of such extent as might be nearly covered by the hand. There was no pain or tenderness. The projecting vessels, covered by epidermis, and having a yellowish-white tint and pearly lustre, were seen and felt, and the prick of the small point of a knife allowed a large drop of limpid lymph to immediately exude. A similar affection of lymphatics occurred during a slight attack of phlegmasia in the right limb, which began as the disease was slowly disappearing from the left. The lymph-angiectasis occurred in an area of skin mechanically weakened by being the seat of closely set spindle-shaped, ribbon-like skin cracks. These cracks were obscured by the lymphatic distension, and did not subsequently become again visible as skin cracks, except in small parts. The lymph-angiectasis was probably the result of general lymphatic tension in the whole limb, the special varicose lymphatics becoming so in consequence of being imperfectly supported by the weakened cracked skin. Similar phenomena were observed in the abdominal skin cracks of pregnancy under circumstances not regarded as morbid.—Dr. PLAYFAIR said that many clinical facts proved that thrombosis of the veins was not of itself sufficient to account for the phenomena of the disease. Thus, there were cases of thrombosis of the veins of the lower extremities, occurring in gouty subjects, in connexion with which nothing like phlegmasia dolens was observed. Dr. Duncan's cases showed the probably intimate connexion between a certain amount of septic absorption and phlegmasia, which was not uncommon in connexion with cancer of the uterus. He did not think that there was ground for assuming that lymphatic obstruction had more to do with phlegmasia than venous obstruction. He had never seen any lymph-angiectasis in puerperal cases, and in some instances thrombosis of pulmonary arteries preceded the phlegmasia.—Dr. GRAILY HEWITT thought there was no doubt that, in typical cases of this disease, both lymphatics and veins were affected. It was known that the venous obstruction originated in coagulation in the uterine sinuses extending to the iliac trunk, and it was probable that the lymphatic thrombosis occurred in a similar way.—The PRESIDENT would not attempt to estimate precisely the comparative influence in phlegmasia of venous and of lymphatic obstruction. He would only say that, while sometimes venous obstruction was certainly absent, we could not say the same of lymphatic obstruction.

Dr. GALABIN brought forward a Case of Extra-uterine associated with Intra-uterine Fœtation, in which Abdominal Section was performed. The patient was thirty-six years old, was married in the spring of 1878, in the summer of that year had an abortion, and in April, 1879, was delivered by forceps of a full-term child. She expected her second confinement in September, 1880, and engaged Mr. Thomas Duke of Rugby to attend her. During the fourth and fifth months of pregnancy she had considerable pain and tenderness in the right side of the abdomen. Two tumours were discovered; that on the left side gave the usual evidences of fœtal life, and was clearly the pregnant uterus. Over the tumour on the right side nothing could be heard by auscultation, and Mr. Duke, as well as several other medical men who examined the patient, concluded that the case was probably one of an ovarian tumour complicating pregnancy. On June 16th symptoms of rupture suddenly occurred, followed by those of peritonitis, and the outline of the right-hand tumour was found to have disappeared. The patient's state having become very critical the author was sent for, and reached Rugby on the evening of the 19th. He was inclined, from the history, to agree with the diagnosis of ruptured ovarian cyst; but the possibility of combined extra- and intra-uterine fœtation existing was suggested. He advised an exploratory operation as the only chance for life, and performed this on the morning of the 20th. A large quantity of blood and clot was found in the peritoneal cavity, and an extra-uterine fœtus contained only in its thin membranes. The placenta, attached to the back of the pregnant uterus and posterior surface of the right broad ligament, was left *in situ*, and a drainage-tube placed in the wound, entering the general peritoneal cavity. The operation was performed under carbolic spray. The patient appeared to be doing well for the first two days, and the temperature never rose above 99·8°. Labour, however, came on on the morning of the 22nd, and a child, which presented by the breech, was delivered stillborn. Though there was very little hæmorrhage by the vagina a great deal occurred through the drainage-tube. On the 23rd the temperature was normal, but hæmorrhage still went on through the drainage-tube, and she died, apparently from loss of blood, on the 24th. The author attributed the secondary hæmorrhage to the shrinking of the uterus in the expulsion of the fœtus, and consequent further detachment of the extra-uterine placenta from its posterior wall. Both fœtuses appeared to be of about six months and a half development, but the extra-uterine fœtus weighed only one pound and a half, the intra-uterine two pounds and three-quarters. A review was appended of similar recorded cases, in all of which the extra-uterine pregnancy appeared to have been of the abdominal form, while in none of them was a complete diagnosis made, while both fœtuses remained within the abdomen.—Dr. ROUTH congratulated the author on his skill and powers of diagnosis. It appeared that death was due to the further detachment of the placenta in labour, and he suggested that it would have been expedient to re-open the abdomen and arrest hæmorrhage by the actual cautery. He had seen adhesions in ovariotomy, even adhesions to the liver, successfully treated by the actual cautery. —The PRESIDENT regarded uncontrollable hæmorrhage as the great difficulty in surgical interference with extra-uterine pregnancy, and this even many months after the death of the fœtus. He did not look with much hope on the actual cautery as a means of arresting this or any kind of hæmorrhage, as he had used it, and seen it used, in vain.—Dr. GALABIN said that on account of the distance of the patient he had not had the opportunity of deciding on the expediency of re-opening the abdomen. He thought that a styptic, such as perchloride of iron, would be more effectual than the actual cautery in arresting hæmorrhage in such a case.

Dr. GEORGE RIGDEN read a paper "On Midwifery in Private Practice during Forty-three Years." 5682 mothers were delivered of 5751 children—viz., 2947 males and 2804 females; 65 were twin cases, and there were 2 cases of triplets. 5422 children presented by some part of the head, including the face; 156 presented by the breech; 89 by inferior, 84 by superior, extremities. There were 45 placental presentations included in the above; 255 children were still-born, 165 being premature; 105 had been dead some time; 759 were delivered by forceps; in 2 cases craniotomy had to be performed. Previous to 1860, forceps were used only once in 222 cases, while in the last twenty years they were used about once in 15 cases. The proportion of stillbirths was but very slightly diminished during the latter period, and the author attributed this slight advantage rather to greater experience than to the more frequent use of forceps. There were 13 maternal deaths—viz., 2 from puerperal convulsions, 5 from peritonitis, 2 from heart disease, 1 from fright, 1 from cancer of the tongue in an advanced stage, 1 from bronchitis, and 1 from scarlet fever.—Dr. EDIS thought great credit was due to Mr. Rigden for his exceedingly low maternal mortality. It was curious that the proportion of stillbirths did not seem to vary with the change from ergot to forceps. He believed that the timely use of forceps diminished materially both infant and maternal mortality, especially in large cities.

Reviews and Notices of Books.

The Factors of the Unsound Mind. By W. A. GUY, M.B., F.R.S. London: T. De la Rue and Co. 1881.

THIS is an important contribution by a physician of great learning and matured judgment to the question of the relationship of mental states to criminality. In his first chapter Dr. Guy deals with illusions of the senses, and he quotes many examples familiar enough to medical readers of perfectly sane persons who have suffered from sense-phantoms of various kinds. Dr. Guy has collected and analysed thirty-six cases of illusions. Of these twenty-eight were males and eight females, and they were of all ages, from four to eighty. Some were in robust health, others were delicate or worn by study. In some the illusions lasted for years, while in others they marked the onset of a febrile attack. The illusions had in some cases a reference to past or passing events, and in others no such reference could be traced. These illusions are not due to the workings of the imagination, but they "start into existence, a surprise and a perplexity." Dr. Guy, however, as a result of his analysis of cases, says: "Among the endowments specially mentioned in some of the most minutely described cases, an active imagination, a retentive memory, an acute perception, and a highly sensitive and sympathetic nervous organisation, are to be noted." This rule was not invariable, and many of the victims of illusions have been persons of a very opposite type. The following list of causes of illusions are given:—(1) Mental excitement and exhaustion. (2) Exhaustion of the strength by watchings, fastings, &c. (3) Convalescence from illness. (4) The onset of inflammatory disorders. (5) Disorders of alimentary canal. (6) Blood changes. (7) Certain poisons, such as alcohol, Indian hemp, and belladonna. (8) Disturbance and arrest of cerebral circulation. (9) Disease of the sense-organs. (10) Convulsive and paralytic disorders. passing allusion is also made to what the author calls *illusive transformations*—i.e., the transformation of common sights or sounds in the mind to things other than the reality. This is common enough in the insane, and is familiar also in cases of delirium tremens.

In the second chapter a delusion is defined as "*an involuntary thought, idea, or belief, without dates or premisses.*" Delusions may have their origin: (1) In illusions. (2) Sudden shock. (3) Visceral disease. (4) Excited emotions. (5) Disappointment or injury. (6) Disordered circulation or disease of the brain.

The analogy between dreaming and insanity, and the origin of the sense-phantoms and delusions of the dreamer, form the subject of the third chapter.

From dreaming, the analogue of insanity to somnambulism, the acted dream is an easy and natural transition. The facts that somnambulism has close relationships with epilepsy and insanity, that, like them, it is hereditary, and that the one condition often passes into the other, are dwelt upon. That remarkable condition, "the mesmeric state," is alluded to as showing how easily the will may be dethroned by artifice. The chapter on delirium serves to show how both illusions and delusions may be produced by bodily conditions and causes well understood and almost reproducible at the will of anyone.

In Chapter IV. many interesting illustrations of incoherence in written and spoken language are given, and their value as evidence of insanity is insisted upon.

The relationship of epilepsy, hysteria, and other disorders which are or may be characterised by convulsive movements is brought prominently forward, and is illustrated by many apt examples chosen from the writings of physicians of all times.

The proposition that madness is often but an intensified emotion is handled with great ability, and there occur in this chapter passages which deserve to be quoted *in extenso.* The leading dispositions of mankind are comparatively few. "Innumerable combinations of these elementary characters, harmonious or discordant, make up the individuals whom we encounter in all societies of men, and in whom outward objects or inward thoughts stir up the various emotions of pleasure and pain, of hope and joy, of love and pity, of pride and vanity, of awe and veneration, of shame, fear, anger, and remorse." The abnormal growth of one side of a disposition may give us individuals "consumed by an insane fear, insane despair, insane hatred, insane love, insane jealousy." "It will be observed," says Dr. Guy, "that I have made no separate and distinct allusion to conscience and the conscientious disposition, though a knowledge of right and wrong figures so prominently in our law courts as the test of criminal responsibility. My motive for the omission is that I do not see any sufficient reason for treating conscience otherwise than as one of the groups of emotions which answer swiftly and certainly to the objects or thoughts fitted to call them into play, or if differing from them in any particular in this, that conscience is maintained in a highly sensitive state by the constant and sustained efforts of the teachers of religion. In the classes among whom vice and crime abound, and to whom the teacher of religion does not gain access, it is reasonable to expect as low a development of conscience as of the other emotions which tend to virtue." That the constant stimulation by religious exhortations, assisted by the fine arts, is sure to produce an insane growth of one side of the character, is shown by the overbearing frequency of one form or another of religious mania.

In a short chapter a few references are made to cases of delirium and nervous disorder brought about by foul air or scarcity of food. "We know," says the concluding paragraph, "that such epidemics as the dancing mania have followed in the wake of pestilence and famine, while the homicidal mania of the French Revolution, and the mixed epidemic of homicide and fire-raising which prevailed during the siege of Paris in 1870, were in part explained by the scarcity of the one period, and the famine of the other."

Dr. Guy's classification of insanity is, primarily, into the *undeveloped*, the *degenerated*, and the *disordered* mind—idiocy, imbecility, and mania. The last class it is which furnishes the debatable criminals; and as a general plea for these unhappy persons Dr. Guy puts forward the argument drawn from a consideration of the modes of origin of the factors of the unsound mind, that an apparently sane person may suffer from "epilepsies of sense, thought, and speech," as well as from convulsive epilepsies affecting the muscles. There can be no doubt of the reality of epileptic insanity, and that epileptics may and do become violent and "mad" under the influence of epileptic sense auræ. The fact that epilepsy may be produced by peripheral irritation—such, for example, as a neuroma—is illustrated by cases.

When Dr. Guy deals with the criminal lunatics, he points out that the difficulty arises mainly with two classes—the imbeciles who have criminal tendencies, and the victims of sudden maniacal impulses. The author's long connexion with Millbank Prison gives him the right to speak on the subject of punishment, and the spirit of common sense tempered with mercy which is manifested in the chapter devoted to the discussion of "the punishment of the madman" cannot but be conducive to the right understanding of a difficult matter. Dr. Guy strongly asserts that for a certain class of criminals the fear of physical suffering is the only deterrent, and he has no sympathy with those who would abolish either the gallows or the lash. Neither the one nor the other has any deterrent effect upon lunatics; and those who have advocated, as Smollett did, the "punishment" of unreasoning beings have outraged both logic and humanity. "If instead of talking of *justice* Smollett had spoken of *mercy* he would have commanded my sympathy, though I must have withheld my consent; for I know enough of madmen to believe that the very kindest thing we could do to most of them would be to kill them; and this is equally true of many a victim of hopeless incurable bodily suffering." The punishment of death has no deterrent influence on persons of unsound mind; on the contrary, there are not few of these whose ambition it is to be hanged. It is clear, therefore, that the public safety is not enhanced by the enforcing of the law rigidly against the insane. The legal views of insanity, and the change which has been undergone by them from time to time, are passed in review in a most interesting manner.

The final chapter, that which deals with the amendment of the law, is perhaps the most practically important of all. The Criminal Code Bill has the following paragraph:—

> "In order to establish a defence on the ground of insanity, it must be proved that the offender was at the time when he committed the act labouring under natural imbecility or disease of or affecting the mind to such an extent as to be incapable of appreciating the nature and quality of the act, or that the act was wrong."

Dr. Guy suggests that the attention of the Court should be concentrated on one plain question: "Is the accused of unsound mind, and was he so about the time when the act was committed—that is to say, about the time when he may be assumed to have been contemplating it?" He also urges, as others have urged, that the scientific witnesses should be appointed *by the Court*, instead of being, as is now the case, selected by prosecution or defence, and mainly on account of some opinions which they have made public. With these suggestions we think all right-thinking persons will agree.

Index Medicus. A Monthly Classified Record of the Current Medical Literature of the World. Compiled under the supervision of Dr. JOHN S. BILLINGS, Surgeon U.S. Army, and Dr. ROBERT FLETCHER. Vol. I., 1879. Vol. II., 1880. New York: Leypoldt. London: Trübner and Co.

THOUGH it is more than one hundred years since the House of Commons voted £15,000 for preparing indexes to its journals, no serious effort seems to have been made, until a few years ago, to produce a tolerably satisfactory index of scientific and medical literature. Much, it is true, has been done by Mr. W. F. Poole of New York for general literature, yet few attempts have been made to systematise and classify the enormous mass of material contained in current scientific and medical literature.

In the year 1860 the Royal Society began the publication of a "Catalogue of Scientific Papers," but the utility of the work is seriously impaired by the defective arrangement. It consists purely of an alphabetical list of authors' names, and is, therefore, almost useless for bibliographical purposes. A distinct advance was, however, made in 1877, when the New Sydenham Society published an important work, entitled "A Medical Digest," prepared with immense care and labour by Dr. Richard Neale, during a period of thirty years. Though the "Digest" did not make any pretensions to be a complete index even to the works named therein, it did, nevertheless, practically form an index to the chief English medical periodical publications from 1837 to 1876. It contained over 90,000 distinct entries, and was itself supplied with a copious index, containing more than 9000 references. But we suspect that the work is not yet sufficiently known. This may be partly due to the fact that it is obtainable only by members of the New Sydenham Society. As we announced some weeks ago, Dr. Neale purposes, with the support of his professional brethren, to publish a new edition independently. This will be brought down to the end of the current year, and, it is estimated, will contain about 20,000 additional references, making in all more than 110,000 references to medical periodical literature of the last thirty-five years. It will then be, even more than at present, indispensable to those who wish to become acquainted with the history of medicine, surgery, and therapeutics during this important period.

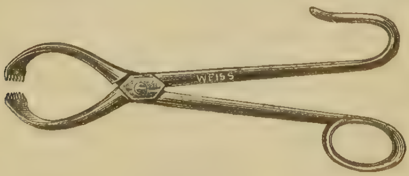
The work the name of which heads this notice is of a different and more pretentious character. It is, professedly, a classified catalogue and record of all the current medical literature throughout the world. Originally started in January, 1879, it has been continued monthly in spite of serious pecuniary loss. Indeed, at the end of the first year the publisher announced that the entire subscription price (for 1879) did little more than pay for the cost of the index to the first volume. With praiseworthy courage, however, the publisher continued the Index for a second year, and again at a loss. At the beginning of the third year, however, the prospect was somewhat brighter. The sum required for the continuation of the Index having been nearly covered by subscriptions and by special contributions to the guarantee fund, the publisher determined to venture upon the publication for another year.

Several medical societies in the United States have voted special sums to a guarantee fund to meet the loss that had hitherto attended the publication of the work. We would fain hope that its success is now assured, and that the subscriptions will in future not only cover the cost of production, but leave a margin of profit. Its discontinuance would be almost a calamity for every intelligent student and practitioner of medicine. It is printed on good paper, in excellent bold type, and is a marvel of accuracy and completeness; it is a worthy complement of the Index Catalogue in course of preparation by the same authors. (See The Lancet, Nov. 20th, 1880.)

New Inventions.

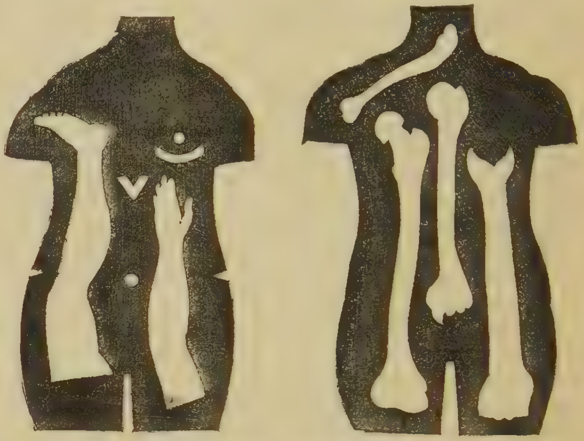
NEW TUMOUR FORCEPS.

These forceps have been devised by Mr. Bellamy, and made by Messrs. Weiss and Son, for seizing and steadying large tumours, such as fibrous, fatty, &c., while being removed by the knife. The objects gained are great leverage, a firm grip of the mass, and ease in manipulation. It is a modification of Museaux's forceps, with more bow in the blades and lithotomy forceps' grip. The hand is liable to get tired and slippery in removing hard tough growths, and he above instrument would seem to obviate these difficulties.



GOYDER'S CLINICAL STENCIL PLATES, (REGISTERED.)

It has always been desirable to record graphically (as well in the note-book as on the patient's board) the position of physical signs and the location of injuries. These stencil plates serve the purposes of the physician or clinical clerk by enabling him to trace outline forms of the body, male and female, on its anterior and posterior aspects. The presence of any physical sign can be depicted, and normal landmarks put in or omitted. The limbs can be drawn, and the position of any tumour, line of incision, excision, or amputation delineated. Lastly, with the plates, outlines of the femur, tibia and fibula, humerus and clavicle, can be drawn, and, by reversing the plate, bones of the opposite side are shown. By sketching in the prominent lines on the respective bones, the anterior or posterior surface is brought out. The ends of corresponding thigh and leg bones united by a few lines show the knee-joint back and front—a joint which is often diseased, and in which morbid physical signs can be easily mapped out. The idea is not a novel one, and has, we believe, been long recommended by Dr. Gee. We would suggest that the plates should be multiplied; for in order to take an exact map of the physical signs of the thorax and abdomen, the outlines of the ribs should be indicated, or at any rate the costal margin, which cannot be done on the plates in their present form. The plates are neatly cut, and put up in a folding morocco case, with a card of instructions, by Messrs. Brady and Martin, of Newcastle-on-Tyne.



Bequests and Donations to Medical Charities. The Exeter Lying-in Charity has become entitled to £200 under the will of the late Mr. Wm. Miles. Surgeon-Major Newland bequeathed £1000 to Mercer's Hospital, £500 to the Hospital for Incurables, and £250 to the Medical Benevolent Fund Society of Ireland. Mr. Edward Baker, late of Clapham, bequeathed, upon the death of his widow, £300 to the Clapham Dispensary, and £200 each to the Brompton Consumption Hospital, the Royal Sea-bathing Infirmary, Margate, and the City of London Hospital for Diseases of the Chest; also the remainder of such part of his personal estate as may be by law applied for charitable purposes to the principal London hospitals, at the discretion of his trustees. The Dundee Royal Infirmary has received £200 by the will of the late Miss Whetson of that town. The funds of the Windsor Infirmary have benefited to the amount of £1000 by the will of the late Miss Louisa Reid of Hyde-park-terrace. Mr. Padmore, late of Hallow, bequeathed £500 to the Worcester Infirmary, and £100 each to the Salop Infirmary, the Worcester Dispensary, and the Worcester Ophthalmic Institution. The Newcastle-on-Tyne Throat and Ear Hospital has received £100 from a benefactor.

The Newport Infirmary is to be enlarged to the extent of making provision for the accommodation of twenty-eight additional patients.

THE LANCET.

LONDON: SATURDAY, JUNE 4, 1881.

DR. CAMERON has given notice in the House of Commons that on an early day he shall move "a resolution condemning the conduct of the Local Government Board in refusing to take the most obvious means of encouraging revaccination, and in witnessing the compulsory closing of small-pox hospitals without causing provision to be made for the reception of small-pox patients." The aim of the resolution is excellent, and its utility would be undoubted if there were any reasonable hope that the attention of the House of Commons could at the present time be seriously interested in the question of the administrative policy of the Local Government Board with respect to small-pox in the metropolis. It would be well that the country should have some authoritative statement of the views that Board entertains respecting the promotion of revaccination (if, indeed, it have any views at all), and whether it has seen or sees its way out of the complicated matter of the small-pox hospital question—a question, it must be remembered, for which the Board is primarily responsible, and, in view of its anomalous relations with the Metropolitan Asylums Board, continues responsible. The Local Government Board, if it has hitherto displayed a lamentable want of statesmanship, has a certain pettifogging astuteness, which is not unlikely to bring confusion upon the heads of its opponents in the House, and, by an ingenious showing of what its strictly legal functions are, prove that it has done all that the law required of it, and in a way that deserves well of the Legislature, if not of the metropolis or the country at large. We shall not be surprised if a resolution condemnatory of the Board becomes in the course of discussion a resolution wholly approbatory, and we may have to admit, despite common sense and common observation, that administratively the present state of things in the metropolis as to small-pox is the best of possible results that could have happened, in the best of governments, in this best of worlds.

As far as revaccination is affected by plenteous supplies of animal lymph, has not Mr. DODSON told us again and again in the House that he has no view of encouraging revaccination by the supply of animal lymph for the purpose, except indirectly as it may furnish a more approved (by some persons) supply of humanised lymph from fresh stocks; and has not the House accepted this statement without indication of dissent? This is the approved principle of the National Vaccine Establishment, and is it for a great Government Department to change principles as easily as gloves? But the circumstances of the present outbreak of small-pox, it may be said, call for a revision of the principle referred to. Perish the thought! It is for epidemics to adapt themselves to proved departmental rules, not for departmental rules to be modified to meet epidemic exigencies. In the one case patient, trustful routine is all that is required. In the other case the foundation of bureaucratic administration would be rendered unstable throughout, and the manner of administration would be liable to be wholly lost in attempts to secure the object for which the administration was designed—a view which, as not formally provided for by the Legislature, and inconsistent with Acts of Parliament, according to the usual rules of interpretation, must be at once repudiated.

The true source of all the infectious hospital troubles in the metropolis rests in the question having fallen into the hands of the Poor Law authorities, mainly from the negligence of the sanitary authorities in the first instance, but afterwards from the perverse action and want of courage and foresight of the Local Government Board in the second, in having determined to pursue one kind of policy in the provinces and another in the metropolis. While using every exertion to divert the charge of infectious diseases from the Poor-law authorities and fix the responsibility upon the sanitary authorities in the provinces, as a question of public health administration, precisely the opposite policy has been pursued in the metropolis. Hence the evils in respect to small-pox hospital accommodation from which we are now suffering. From the commencement of our troubles on this question to the present time the subject has been considered by the Local Government Board, above all things, as a matter of Poor-law administration, and with the result that has surely followed all meddling with sanitary or public health matters by Poor-law administrators. The administration that could not conduct the sanitary government of a workhouse has failed almost necessarily in governing the more complicated arrangements required in dealing with epidemic small-pox amidst a vast population. The Local Government Board and its metropolitan adumbration, the Asylums Board, have come to grief in their work with reference to small-pox just as the old Poor-law Board and their representatives on the different Boards of Guardians came to grief in the sanitary administration of workhouses. How does it happen that the circumstances now being brought to light as to the influence of our large small-pox hospitals upon the neighbouring populations had to be discovered by outsiders, and were not recognised, and the evils rectified as they occurred, by the officers of the Local Government Board? The subject did not concern the duties, at least legally, of the Metropolitan Asylums Board. But the Local Government Board, possessing the functions both of Central Public Health and Poor-law Authority, had full powers of inquiry. Why were these not exercised when the earliest rumours of mischief from the hospitals got afloat? But throughout the whole of the difficulties connected with this subject the Board has shown itself peculiarly careful to exclude them from consideration as a question concerning its public health administration. Indeed, what can be more astonishing and inconsistent with the question to the Central Board having presented itself as one of public health, than the fact of its having assented to the Metropolitan Asylums Board borrowing a hulk of a line-of-battle ship from the Admiralty for use as a small-pox hospital in the Thames? If there be a construction least fitted for nursing small-pox patients on board, in the interests of the patients, it is an old hulk; if there be a disease least appropriate to be treated on a hulk it is small-pox. Further, if it should prove that the accumulation of small-pox in separate hospitals is apt to cause in some way or other the presence of the disease in houses situated within half-a-mile radius of the hospital, the conditions of such diffusion must be expected to be found in greater intensity in connexion with a hulk occupied by small-pox patients. Moreover, the belief that more effectual isolation will be secured in a floating hospital is, we believe, a delusion, unless special methods of guarding the ship are adopted, particularly if the hulk is to be moored, as we understand, off Deptford or Greenwich—that is to say, in the busiest part of the great highway of the river. It is difficult to believe that this matter has been submitted to the Medical Department of the Government, and that it is any more than one of those happy-go-lucky measures of the Asylums Board and Local Government Board which have so markedly characterised their doings during the present epidemic of small-pox.

◆

FROM the earliest dawn of scientific medicine electricity, in some shape or other, has been applied to the cure of disease. The ancients, although entirely unacquainted with its principle of action, knew some of its manifestations, and attempted to turn them to account in therapeutics; but it was only with the discovery of the first condensators that the rational use of electricity began. The Leyden jar was unquestionably the starting-point of electro-therapeutics. When it became possible to administer powerful shocks by drawing sparks from a reservoir, medical men began to employ them, and remarkable effects were produced. It is true that ROLLET and DU FAY had before this time taken sparks from the isolated subject, but they had not observed the production of muscular contraction by electrical influence. DE HAEN, one of the most illustrious physicians of the eighteenth century, seems to have made an extensive trial of the new remedy. He reports numerous cures of paralysis, chorea, and other nervous affections. But one of the most remarkable advocates of medical electricity was JOHN WESLEY. Amongst the various diseases which he mentions as having been cured are: blindness, chlorosis, *hysteria*, contraction of the limbs, lameness, palsy, pain in the back, sciatica, and deafness. We find in this list most of the complaints which are really capable of deriving advantage from the action of the electric fluid as at present employed; and one of the most remarkable coincidences that may be noted in this respect is that injurious as well as favourable effects were not unfrequently observed—certain patients struck with paralysis, others contracting nervous affections; and the cases may be compared with those which under DUCHENNE'S treatment became blind whilst being galvanised for neuralgia. Some twenty years later an able and systematic advocate of electrical treatment, MAUDUIT, expressed the opinion that electricity had a most positive and beneficial influence on nutrition, circulation, and secretion. A series of papers was presented by him to the then existing scientific bodies, and attracted considerable attention. But shortly after, at the close of the last century, the discovery of galvanism, whilst giving a new impulse to the medical use of electricity, entirely superseded the methods then employed, and dethroned franklinism, as it might have been thought, for ever. Forty years later galvanism, in its turn, fell into disuse, its place being taken by faradisation, which, after long reigning supreme, gradually gave way before a partial restoration of its rival, and now static electricity, long discarded from practice, has again returned to favour. The seven forms of its application recommended by the earlier electricians are described by SIGAUD DE LA FOND as—(1) The electric bath, in which the subject, placed upon an insulating stool, is put into communication with the prime conductor, which brings the surface of the body into a state of positive or negative tension, the fluid escaping continually from the hair, fingers, and the general surface. (2) The withdrawal of sparks from the body, electrified as previously described; this consists (3) in pouring, so to say, a series of sparks by means of a special conductor upon the diseased part which it is intended to bathe in electricity. (4) Next we have electrical frictions, which consist in the passage of a metallic rod upon the body of the patient previously electrified and covered with flannel or some other insulating material. The result is said to be rapid, the superficial local irritation producing a marked degree of formication, which, according to the author, is a sovereign remedy for chilblains. (5) Then comes insufflation, the mildest method of applying static electricity, and which is performed by approaching a metallic point communicating with the source to different parts of the surface; the patient then experiences the sensation commonly known as the electric *souffle*. (6) The converse method consists in exhausting the subject's electricity by a metallic rod, which instead of communicating with the machine is connected to a chain which trails on the ground. (7) Lastly, we have the electric shock. We find in these various methods the greatest analogy with modern practices. Static electricity is at present administered by means of the electric bath, the patient being insulated and placed in communication with the prime conductor. In this condition the electric *souffle* "irritation"—the electric aigrette (exhaustion), or the removal of sparks, can easily be employed by the same means as were in use eighty years ago. The chief difference lies in the great improvements which have been introduced in the construction of apparatus, and the vast amount of electricity which can be supplied to the patient at a given moment. Under these conditions the electric shock, one of the most powerful weapons of the old system, has been laid aside as equally painful and useless. An eminent contemporary expresses the opinion that of all the sensations which can be experienced none can be more disagreeable than the commotion produced by a Leyden jar, with the exception, perhaps, of being hanged. Among the physicians who have chiefly been engaged in the revival of static electricity may be mentioned Dr. TRIPIER, Dr. ARTHUIS, and Dr. VIGOUREUX, whose experiments in the service of Professor CHARCOT have attracted considerable attention. Some account of these will be found in a recent number of the *Revue Mensuelle*. The principle advantages of this mode of treatment may be rapidly summed up under a few headings. 1. Anæsthesia: The electric bath, methodically applied with a sufficiently powerful machine during a period of twenty to thirty minutes, and repeated about three or four times a week, has a most remarkable influence upon the cure of anæsthesia. It is, of course, in hysteria that the most rapid, and, it might almost be said, miraculous cures have been effected.

No wonder, since even the application of a piece of wood, or a layer of collodion, has sufficed in certain cases to give a good result. But loss of sensibility has been repaired in far more unpromising cases, where organic injury to the nervous centres had been distinctly ascertained; and where the normal condition has not been restored, in other ways, a great improvement has been achieved in this respect. 2. Contracture, whether hysterical or of a less immaterial nature, has also been successfully treated by franklinism in our own time, as, in days gone by, the Reverend JOHN WESLEY, as we have seen, testified to the marvellous results produced by its use. 3. Chorea and nervous trembling have in various cases been radically cured by the same means. 4. Suppressed menstruation has been restored after a few sittings. 5. Hypersæsthesia and neuralgia have in some instances been relieved, in others radically cured. Our forefathers stated that hypochondria was among the diseases which might be checked by franklinism. We need not therefore be surprised to find that neurasthenia, an ailment closely allied to hypochondria, if it is not the same malady under a more recent and dignified name, has often been considerably ameliorated by the electric bath. That reverses will occur in the practice of everyone who adopts static electricity as a mode of treatment is a fact which can easily be foreseen. All that can be claimed from a positive knowledge of authentic cases is that relief will sometimes be obtained where pharmaceutical treatment had failed as completely as galvanism or faradaism in restoring health. The subject is one which deserves the attention of medical men, and which will, undoubtedly, reward the labours of all scientific observers who may choose to investigate it. Possessing, as we do, generators of a power unknown to our predecessors, better acquainted than they possibly could be with the physiological action of the electric fluid under its various forms, and rich in the accumulation of an immense store of clinical knowledge, we can easily avoid the errors formerly committed in theory, and obtain more satisfactory results in practice. At all events one thing is clear. Electricity may be applied to the treatment of disease in all its varied forms, and we should avoid an exclusive and egotistical attachment to any one method recommended by a particular authority.

◆

AN influential meeting was held at Brighton on Tuesday, to consider the subject of Medical Reform, with reference to the education of our students in the practice of their profession. This is the third large meeting of the kind which has taken place within the past few weeks, first at Leeds, then at Bradford, and now at Brighton, so that we have had an opportunity of hearing the matured views regarding medical reform of some of the leading practitioners in the Northern and South-Eastern counties of England. So far as we can judge, the larger proportion of the profession is of opinion that the time has come for legislative interference in this matter. This opinion is not based on a mere love of agitation, but is founded on the belief that the curriculum and method by which our students become qualified to practise are defective, and that the existing licensing authorities of the United Kingdom, after ten years' effort, find themselves incapable of sinking their minor differences, and uniting to promote the common welfare of the profession. Some of the most prominent members of the medical corporations, however, still console themselves with the idea that the existing movement in favour of medical reform lacks vitality so far as the bulk of the profession is concerned, that it is something which has been created and kept alive by the editors of certain journals and a few restless individuals; but if such were the case, how is it possible, as Dr. C. HOLMAN remarked at Brighton, to account for the opinions expressed by the various gentlemen who have spoken at recent meetings on medical reform, as he argued these gentlemen are neither editors nor agitators, but some of the most influential and successful men in the profession? Beyond this, many of them employ young practitioners as assistants, and have an opportunity of forming an opinion as to the results of the present system of training students with reference to its capability of producing men who are fit for the work of their calling, and they have arrived at the conclusion, which is also entertained by the majority of the profession, that the education of medical students is unquestionably faulty, and they see no reasonable hope of improvement under existing circumstances. This is the motive power—the secret of the present movement in favour of reform. Medical men, as a rule, had no wish whatever to break away from the old corporations; they have waited patiently, and striven hard to induce our medical authorities to combine for the common good of the profession; but, weary of promises for conjoint action on the part of the corporations, they now affirm that the time has arrived for legislative action. We have endeavoured, and shall continue to strive, to give expression to the views of the profession on this subject. The meetings already held have not been promoted by us, but we, and the profession generally, are nevertheless under a deep sense of obligation to the gentlemen who have taken part in these meetings; for unless medical men come forward and speak out plainly it is difficult for us to gauge the depth of feeling that exists on the subject, and it is impossible for the members of the Royal Commission engaged on Medical Reform to arrive at a satisfactory conclusion unless the profession, through its representatives, now come to the fore and state their grievances, together with the measures they propose to overcome existing anomalies. In fact, as Dr. WITHER MOORE, the President of the meeting at Brighton, justly remarked, the Government cannot be expected to consider a matter of the kind until the profession has made up its mind what it really wants.

We confidently believe that a large majority of professional men have made up their minds and demand an alteration in the constitution of the General Medical Council. The profession assert that in their opinion the number of the Council should be reduced by one-half, that it should be endowed with the responsibility and real powers of a Council of Medical Education, and that its members should be elected by the medical practitioners of the United Kingdom. On the other hand, it is equally certain that some of the most influential men in the profession affirm their belief that a Council partly elected by the profession is not to be thought of. The reply is, What has been the outcome of the work performed in the Council by some of those gentlemen who are loudest in condemning the proposed change?

It is true, as DR. R. BOWLES contends, that the lack of results from their deliberations is in a large measure attributable to the Medical Act of 1858, under the provisions of which the Council work. But what reason is there to suppose that the bulk of professional men throughout the country are incapable of forming an opinion regarding the qualification of individuals best fitted to perform the work required of members of the Council? These gentlemen certainly know very well whom to trust when they require an opinion on professional matters, and they may equally be trusted to elect good Councillors.

◆

DR. LYONS, the member for Dublin, acted with perfect *bona fides*, and in a manner which must create a strong claim to the respect of his profession, in declining to present a petition which the King and Queen's College of Physicians in Ireland has seen fit to address to the House of Commons in favour of legal as opposed to medical coroners. This corporation has long held a position strangely out of sympathy with the profession on subjects of education and qualifications, and it is perhaps in harmony with the traditions of the King and Queen's College that it should run directly counter to the best interests of the profession in regard to any matter of practical concern. Its most recent exploit is the drafting of a petition asking "that every coroner should be either a barrister-at-law or on the roll of solicitors," and arguing that "while medical evidence is essential for the efficient conduct of a coroner's inquiry into the cause of death, it by no means follows that there should be a medical judge to try cases where medical evidence may form an essential portion of the case." Meanwhile the profession contends, as it has always contended, that no non-medical judge *can* weigh the skilled testimony of a pathologist. Mistakes of the kind now made by the King and Queen's College of Physicians in Ireland are the outcome of mingled ignorance and impracticability. Persons who make proposals like those embodied in this petition are obviously unacquainted with the history of the Coroner's Court, and cherish a dreamy view of its assumed dignity which is incompatible with any sound conception of the needs of the case. Coroners do not "try cases"! The *sole* purpose of an inquest is to ascertain the cause of death. It would disorganise the whole judicial system to magnify the office of coroner in such fashion as to make him a petty judge, at the foot of the administrative system. This is what the advocates for legal coroners are striving to accomplish. There is no need of such a Court as they seek to make out of the remains of the coroner's office. To investigate the causes of death in a district there must be a public official, and none can be so fit for the proper discharge of duties accruing to such an office as medical men. They alone can carry an inquiry of this nature to its legitimate issue by the most direct, efficient, and, let us say, the cheapest route. When a medical corporation goes out of its way and flagrantly oversteps the boundary line of its province to offer suggestions to Parliament, it is unaccountable that these should take the form of recommendations antagonistic to the common-sense instinct of the medical profession, and not less at variance with the intelligent opinion of the country. DR. LYONS deserves the thanks of his brethren on both sides of St. George's Channel for the wise step he took in refusing to be the agent of a body of professional gentlemen so demented as the College of Physicians in Ireland has shown itself.

◆

WE have recently published several letters from correspondents (some public vaccinators) complaining of the inefficiency of the vaccine lymph issued by the National Vaccine Establishment. Certain of the complainants are men too accustomed to vaccinate to permit it to be inferred for one moment that there can have been any shortcoming in the operative procedure, and in a few instances the failure in the use of the lymph has been too uniform and repeated for it to be attributed to any other cause than the want of activity in the fluid. It is unfortunate that this question should be raised at the present time, when, in the public interest generally, it is desirable that confidence should be maintained in the central lymph establishment and its issues; but at the same time it is natural, as no doubt the demands for lymph from the establishment exceed the normal proportion. We hold this subject so important that we have sought independent information with regard to it in the metropolis and elsewhere; and we find on the one hand that while not a few vaccinators who have had and have occasion for using largely lymph obtained from the National Vaccine Establishment cannot speak too highly of its character for efficiency and certainty in use, others have lost all confidence in it, and if they have occasion to procure fresh supplies of lymph do not seek them at Whitehall. From this we infer that the vaccine lymph issued from the National Vaccine Establishment is more variable in quality than should be, and that in the interests of the establishment and of vaccination generally the Local Government Board should institute some inquiry into the cause of this variability with a view to remove it, if it should be found to depend upon remediable causes. If this be not done, and that pretty quickly, and the question be suffered to slide, as the rumours about the Hampstead Hospital were allowed to slide, the Local Government Board will possibly find that while it has been sleeping others have been wide awake, and a matter which in the first instance had concerned the National Vaccine Establishment alone had developed until it had come to concern vaccination generally. It does not follow that with regard to questions to which the Local Government Board chooses to shut its eyes other persons interested in them will elect to follow the same course. The policy of the blind leading the blind can have but one result; but it may be doubted, having regard to the present state of the small-pox hospital question in the metropolis, whether the Local Government Board is yet prepared to accept this uniformity of the result. But at least it should feel assured that this is not the time to have the question of dealing with the metropolitan epidemic of small-pox complicated by doubts as to the efficiency of the lymph issued from Whitehall, nor to risk bad or imperfect vaccinations and revaccinations from the use of feeble or worthless lymph.

THE next examination for the certificates in Sanitary Science given by the University of Cambridge will commence at Cambridge on Tuesday, Oct. 4th. Any registered practitioner may present himself who is in his twenty-fourth year. Applications for admission or for information should be addressed to Professor Liveing, Cambridge.

Annotations.

"Ne quid nimis."

THE HOSPITAL SUNDAY FUND.

THE Council of the Hospital Sunday Fund met on Monday, under the auspices of the Lord Mayor, who shows the most kindly interest in the success of the Fund, and has agreed to attend officially at Westminster Abbey in the morning and at St. Paul's in the afternoon of the 19th, where Her Majesty's judges, too, have consented to attend. The Council has unanimously determined that it cannot give a grant to Surgical Appliance Provident Associations which require a multiplicity of letters in severe cases, and the public will heartily support the Council. It is wonderful that these associations do not see how strong public feeling is against their rule. The Eastbourne Convalescent Hospital having made a representation that it could not give more than ten letters for every hundred guineas granted by the Fund, and the matter having been considered by the General Purposes Committee, the Council, on the motion of Sir Sydney Waterlow, unanimously recommended a grant for this year on these terms. It is no doubt a large sum for the Council to pay, but the hospital has large expenses and deals generously with its subscribers, and through them with its patients. Dr. Glover seconded Sir Sydney's resolution, observing that whereas the question with this hospital last year was one of principle, this year it was merely one of detail, which might be left to time and the authorities of the Fund and the hospital respectively.

CONVERSAZIONE AT ST. BARTHOLOMEW'S HOSPITAL.

ON Friday last a conversazione was given by the governors and medical staff of this ancient hospital, which was attended by the Prince and Princess of Wales, and nearly 2000 guests. The school was formally opened by the Prince about eighteen months ago, but since that time has received many additions, and is now in thorough working order, and it was thought by the staff to be a good opportunity to show to the public the arrangements that have been made for the instruction of the students. The space between the quadrangle and the new buildings of the school was converted into a large reception-room, capable of holding 600 persons and more. The visitors were received by Sir Sydney H. Waterlow (the treasurer of the hospital) and his daughters, Dr. Andrew, the senior physician, Mr. Savory, the senior surgeon, and other members of the staff. From the reception-room passages led on the one side to the library, well filled with books and finely fitted up with oak panelling, to the physiological class-room and to the museum, and on the other side to the anatomical theatre, the medical theatre, the dissecting-room, and, at some distance, to the dispensary of the hospital, where the manufacture of various medicines was exhibited. The walls were everywhere lined with pictures and drawings. In the library was a remarkable piece of Japanese bronze work, and a collection of Cloisonnée enamel, lent by Sir Trevor Lawrence, as well as a series of engravings by Bartolozzi, lent by Mr. Seabright and Mr. Morris. The physiological class-room contained a large collection of physiological and electrical apparatus, with microscopes and microscopic objects of interest, lent by the leading firms in the metropolis. In the museum a potter was engaged with his wheel, and proved a special attraction, and Sir W. Muir had been kind enough to lend the series of the models of ambulances of all countries from the earliest times to the present, which is kept in Netley Hospital. The band of the Coldstream Guards played at intervals in the museum. Glee-singing by the London Vocal Union, and the performances of Sibold's string band, contributed to the amusements of the evening. Refreshments were served in the great hall, which was entered through the treasurer's house, and the walls of which were adorned with many paintings of value. The entertainment was a great success.

TRAINED NURSES FOR THE SICK POOR.

AN Association having for its object the provision of efficient nursing for the sick poor in their own homes must command the sympathy of the medical profession in a great degree, because it is in their own homes that the poorer classes chiefly need assistance. Hospital charity has its legitimate sphere, but it is not expedient that it should be allowed to encourage the poor to seek relief from the burdens of sickness by invariably flying to the hospitals. What has been urged against the cultivation of a confirmed and hereditary habit of recourse to Poor-law relief, on the smallest pretexts, may be urged with equal force and cogency against a system of hospital administration and extension which fosters a habit of sick-hospitalism. We are not, however, equally sure of the other objects which the Metropolitan and National Nursing Association proposes to itself—namely, the raising of the standard of nursing and improvement in the social position of nurses. There can, of course, be no direct objection to raising the standard of nursing, if by that the Association means rendering nurses more obedient to the will of medical men, and less disposed to trust to their assumed knowledge of "treatment," than they have recently shown themselves; but, it must be confessed, we view with suspicion all these movements. Even the Association for the Provision of Aid for the Wounded and the Injured by Street Accidents has begun to "examine" its pupils as to the measures desirable for the treatment of "emergencies," the exanthemata being included in the list! We stand in dread of elevations of the standard of quasi-medical work. They too often mean elevation to a grade at which the sort of "medical" work done by lay agency becomes ridiculous, if not positively mischievous. Excellence in nursing should consist in implicit and intelligent obedience to the injunctions of the medical man in charge of a case. Again, we have our misgivings as to the policy of making improvement in the social position of nurses an object. If nurses are proficient as skilled servants of physicians in attendance on the sick, their position *will* improve so far as it is desirable that it should do so; but it is difficult to imagine what improvement can be expected beyond that of better pay for better work. The bad old class of nurses satirised by Charles Dickens in his portraiture of "Sairey Gamp" has passed away. There is still room for improvement in the manners, and even greater scope as regards the modesty and obedience, of nurses; but we do not think this improvement is to be sought by seeking a better social position for members of the calling. Housekeepers do not find that the measures which have been taken for the social "elevation" of domestic servants have led to substantial improvement in the class of cooks and housemaids. The notion of lady-helps may be dismissed as absurd, and the class of lady nurses will not be perpetuated. Nurses must always be *servants*, and they cannot safely be permitted to rise above that position in society. The more respectable they are the better, provided always their respectability does not interfere with their obedience. The main object of this Association is commendable in the highest degree, and we wish it every success; but as regards its secondary objects we are not so well assured, and would gladly see them practically subordinated.

CONTRIBUTION TO THE STATISTICS OF MYOPIA.

DR. O. INST of Zittau in Saxony, in a note which appears in the just published *Archives of Ophthalmology*, states that he has examined the eyes of 1229 pupils of the two high schools of Zittau, the one of which was erected in 1866, the other in 1871, and in both of which the hygienic conditions of light, space, and arrangements of furniture leave nothing to be desired. The contrast between them and the dark rooms of our older schools is striking. The examinations were made in the same room, under equable artificial illumination, both with glasses and the refraction ophthmaloscope, mostly without artificial mydriasis. Only those cases were entered as myopia which showed a decided improvement of visual acuteness by concave glasses, and whose myopia was verified by the ophthalmoscope. In some instances good vision could only be obtained by the aid of a convex glass, nevertheless there was no ophthalmoscopic myopia. The well-known affection of spasm of accommodation, represents, he thinks, the transition from the hyperopic into the myopic refraction. He has met with a few cases in which repeated atropia treatment each time produced a temporary good result, but did not prevent the development of permanent myopia. The percentage of myopia in the seven classes of the new high schools was as follows:—25·7, 11·4, 22·2, 43·6, 45·0, 80·0, and 58·8, which, leaving out the accidental inordinate figures in the first year and the sixth, agrees well with the results obtained by Cohn and other observers. Myopia being as frequent in the new schools of Zittau as in other educational institutions of the same kind, we may fairly conclude that it does not chiefly result from insufficient illumination of the school-rooms, but rather from the great and ever-increasing demands on the industry of the pupils at home, forcing prolonged labour on their eyes during the evening hours, frequently by insufficient artificial light. Hence, though far from underrating the dangers of bad sanitary conditions in the school-rooms, Dr. Inst urges the necessity of sparing children's eyes the fatigue of evening work as much as possible. In regard to treatment, he thinks, with the majority of ophthalmic surgeons, that the effects of atropine are only temporary, and states that he intends to try convex glasses, a proceeding that, with Knapp, we believe is fraught with danger by aggravating the injurious habit of holding objects nearer than the position of the far point of their distinct vision requires.

THE RECENT COLLIERY ACCIDENT AT DEARHAM.

AN inquest, which had to be adjourned, was held a few days ago on the body of Robert Highmore, a miner, killed by a stone falling from the roof of the colliery. He was treated by Dr. Crerar of Maryport and his assistant for dislocation of the clavicle by bandaging and rest. There was at first extreme collapse, but after the lapse of three or four days he was progressing, in their judgment, satisfactorily, when they were dismissed to make way for Dr. Spurgin and Dr. Jackson. Dr. Spurgin's account of the man was that he was suffering from dyspnœa; respiration 80; pulse 125, feeble and weak; tongue furred; expression very anxious; eyes very brilliant; and a general state of high fever, with rusty expectoration. This was his condition a day after that on which Dr. Crerar had discontinued attendance, and on which he describes him as having nothing in his state to cause death. Dr. Crerar and his assistant both refused to give narcotics. Dr. Jackson, who saw him before Dr. Spurgin, sent four pills with half a grain of morphia in each, of which one was taken, and Dr. Spurgin injected hypodermically a quarter of a grain. The chief discussion at the inquest was as to the respective effect of different treatments by bandaging and by narcotics. We must leave this to the judgment of medical men, only observing that after such injuries bandaging and rest are most essential elements of treatment. Apart from all questions of the applicability of narcotics in such cases, we think it most important not in any case to send out morphia in half-grain doses, to be repeated every half-hour till sleep is produced. The idea that a bandage would drive a fractured rib, even if such existed, into the lung will not bear discussion, and was not seriously maintained either by Dr. Spurgin or Dr. Jackson. We can only express regret and surprise that the coroner, though occupying two days in this inquiry, did not order a post-mortem to settle differences of opinion and to give accuracy to judgments on the conduct of medical men.

ERICHSEN MEMORIAL FUND.

WE understand that at a meeting of Mr. Erichsen's old colleagues and pupils, recently held at the house of Mr. John Marshall, F.R.S., it was proposed to endeavour to obtain some permanent memorial of Mr. Erichsen's long connexion with and great services to the School of Medicine of University College. The approaching completion of his term of office as President of the Royal College of Surgeons being considered as a fitting occasion for such a monument, it was decided that steps should be taken to invite former students of University College, and others of Mr. Erichsen's friends, to contribute. The memorial is, we believe, to include a bust of the eminent surgeon, which it is proposed to place in University College. The name of Mr. Erichsen is so highly respected, and so well known in connexion with his work on surgery, not only in Great Britain and the Colonies, but also throughout Europe and the Continent of North America, that very many, we are sure, will be glad of this opportunity of contributing to a testimonial to one who has done so much for the honour of British surgery. Subscriptions to the "Erichsen Memorial Fund" may be sent either to Mr. Marcus Beck, 30, Wimpole-street, W., who has undertaken to act as honorary treasurer; or to Mr. W. A. Meredith, 14, Old Burlington-street, W., the honorary secretary. No subscription is to exceed two guineas in amount.

THE HOTELS OF ROME.

THE *Italian Times*, the English journal published in Rome, has established a Commission with a view of inquiring into the sanitary conditions of the hotels of the city, and of suggesting such improvements in them as may be found requisite. The Commission is composed of Dr. L. Aitken, Dr. Erhardt, Dr. Fiordispini, Dr. Manassei, and Dr. J. H. Thompson. The conception of this Commission has been very well received by hotel managers, to their credit be it said, and it has commenced its work with good promise of being carried to a successful issue. It is a kind of work which must exercise the best effect upon visitors, in giving them confidence that they may enter the hotels of the city without serious risk of suffering from the defects of drainage and water-supply which are so largely believed to attach to them. For it is idle to deny that the reputation of Rome as a resort for tourists has been greatly prejudiced by the fear that the sanitary arrangements of its hotels are far from what they should be. We regret to observe that the Italian Medical Association has taken umbrage at this Commission, and has summoned a meeting to discuss "the measures to be taken in view of the arbitrary interference of certain foreign medical practitioners with the hygienic condition of Roman hotels." But if neither the Municipality nor the Association has seen its way to do this in the interest of foreign visitors, the world in general will feel only too much obliged to the proprietorship of the *Italian Times* for having had the genius for seeing a way of doing the work, and forming an agency which gives promise of its being well done, and which, moreover, meets the approval of the hotel keepers themselves.

THE APPOINTMENT OF A HOMŒOPATH AS MEDICAL OFFICER OF HEALTH AT HASTINGS.

A MEMORIAL drawn up and signed by a considerable number of influential ratepayers has been presented to the Mayor of Hastings, requesting him to convene a public meeting to protest against the recent appointment of the present medical officer of health, which was made contrary to the general wish of the inhabitants. As is well known, this gentleman is a homœopath, and the memorialists urge that the appointment is calculated to do infinite damage to the trade and prosperity of the town as a health resort, since members of the medical profession will refrain from recommending their patients to visit the town if the step that has been taken is maintained. The Mayor, though he admits the right of the inhabitants to call a public meeting, declines to do so himself, as the matter he thinks is entirely within the province of the Town Council, and any action on his part would be anomalous and unprecedented. We hope this decision on the part of the Mayor will not prevent those ratepayers who have the best interests of the town at heart from summoning a meeting, with a chairman of their own, to discuss this important subject. The material welfare of the two towns, Hastings and St. Leonards, will, as the memorialists state, suffer considerably unless the profession and the general public receive an assurance that sanitary matters are efficiently conducted. How this can be the case if the present state of matters continues we are at a loss to conceive. The duties of a health officer constantly involve questions of professional etiquette of the most delicate nature; and a gentleman who has the entire confidence of his professional brethren, and can rely on their cordial co-operation and support, is best able to carry out matters of sanitary reform, and deal promptly with difficulties in times of emergency, which would be impossible in the case of an unpopular man, to whom such support would be given grudgingly and of necessity. The competition among health resorts is now so keen that no town can afford to handicap itself unfavourably in the race by an indifference to health matters. In considering the relative advantages of health resorts having many characters in common, any suspicion of there being a hitch in the sanitary arrangements of any one of them will be sufficient to ensure a casting vote being given against it. Moreover, the ratepayers of Hastings credit the members of the medical profession with strange magnanimity if they suppose that practitioners will send patients to a town where, if attacked with any epidemic disease, they will be brought into direct contact with practitioners who hold views diametrically and irreconcilably opposed to their own.

REMOVAL OF THE KIDNEY FOR NEPHROLITHIASIS.

AT the Charing-cross Hospital is a lad aged fifteen, from whom Mr. Barwell removed a kidney on May 5th, and who is now convalescent. The boy had been under observation for about a year with pyelitis and retro-peritoneal abscess. An incision was made about ten months ago, with the effect of mitigating the symptoms. The wound had healed, leaving only a sinus. In April, by sounding through this passage, Mr. Barwell detected a stone. Yet although the lad was becoming very anæmic, with irregular hectic temperature, no consent for operation could be obtained until the above date, when lumbar nephrectomy was performed. Two peculiarities rendered the removal unusually difficult—viz., the dense thick cicatricial tissue and the proximity of the rib to the ileum. Mr. Barwell cut through the tissues, and came upon the kidney with the stone impacted. An endeavour to extract this latter caused copious bleeding, hence the operator rapidly enucleated the gland, and passed a ligature round the pedicle *en masse*. Since want of room forbade removing the kidney entire, it was divided and extracted in two parts. The operation was thus completed very quickly, and with scarcely any loss of blood. Since then the boy has been going on uninterruptedly well, his temperature becoming normal and regular, the wound being now nearly healed. This is, we believe, the second successful case of removal of the kidney for stone.

EMPLOYMENT FOR SOLDIERS' WIVES.

A FEW years ago, in Dublin, if we remember rightly, the important step was taken by an army medical officer of establishing a class for the instruction of soldiers' wives in the duties required of midwives. The object of the promoter of this praiseworthy measure was double—that of providing in each regiment one or more qualified nurses whose services would be available for the wives of soldiers in the colonies, where such aid is often scarcely to be procured, and of training the women for a special duty, which they might turn to profitable account both during the period of their connexion with the army and after that had ceased. Another step in this direction has just been taken by the formation of an association for the instruction of soldiers' wives in general nursing. Last week a meeting was held at Woolwich in connexion with the association, and there was no lack of distinguished patronage, Viscountess Strangford, Lord Chelmsford, Sir Frederick Roberts, and General the Hon. E. T. Gage taking part in the proceedings. Major Duncan, R.A., stated that the Field-Marshal Commanding-in-Chief took a warm interest in the question, "and had addressed a circular letter on the subject to all the commanding officers in the service, of whom three-fourths had answered favourably." The object in view is very commendable, but we doubt whether the promoters sufficiently realise the difficulties likely to be encountered. A large proportion of soldiers' wives are women who have not the qualities required in good nurses, and the selection of those who are to be trained must be a task of great difficulty. We cannot for a moment suppose that it is intended to train all the women of a regiment for such duties, and we have no indication of the manner in which, or the persons by whom, the selection is to be made. Then, again, there is the difficulty of withdrawing these women from their families. Who is to care for their children while they are engaged at the hospital? Unless the selection is made with judgment and a very careful supervision is maintained over the nurses, we fear the results will prove far from satisfactory. We are not much impressed with the sagacity shown by Lord Chelmsford in his remarks on the subject. He observed that "all the good results which had followed the arrival of Florence Nightingale and her band of nurses at Scutari were to be yet achieved in similar cases by the soldiers' wives." Is it possible that Lord Chelmsford has failed to recognise in Florence Nightingale a woman in ten thousand—ay, in a hundred thousand;—and does he really expect results from the soldiers' wives such as were obtained by that remarkable lady and her band of educated nurses? If he does, we have no hesitation in predicting failure and disappointment. And what are we to say of his anticipation of the occurrence of similar cases to those of Scutari and Balaklava? Have the military authorities profited so little by the sad experiences of those days as to justify his lordship in predicting a similar fiasco? We sincerely trust, however, that wise counsels may prevail, and that by judicious selection and careful administration much good may be effected, even though it does not amount to anything like that foreshadowed in the speeches at the meeting.

THE COMMISSIONERS IN LUNACY AND ASYLUM REPORTS.

OUR readers will have noticed that for some years past we have avoided, as far as possible, any formal reference to the printed reports of asylums. The time has now arrived when it may be well to state the grounds of this reticence. We make no apology for speaking plainly. The facts are these. Under the system which requires or allows the Commissioners in Lunacy to write the reports of their visits to asylums in the books of these institutions, and which permits the compilers of asylum reports to reproduce these reports in their pages, the records left by the Commissioners have come to be nothing more or less than testimonials left with the authorities of asylums in return for the courtesy shown during an inspection. This is a most disastrous condition of matters, and we venture to suggest that it is one which demands the very serious consideration of the Legislature. The subject is one of the gravest practical interest to the public, and whatever else in connexion with Lunacy may be played with or postponed, this little matter at least might be promptly reformed.

THE BLOOD IN CASES OF EXTENSIVE BURNS.

THE congestion of the internal organs in cases of severe burns has long been a familiar fact to surgeons. But it has been questioned whether the marked constitutional symptoms produced by such injuries are to be entirely explained by this congestion, and by the direct influence of the burning upon the cutaneous sensory nerves, or whether part of such immediate symptoms, and also the later phenomena, may not be caused by some intimate change in the blood itself. Hoppe-Seyler has recently examined the blood of two patients extensively burnt, and he found that in one of them 2·4 per cent, and in the other 5 per cent. of the hæmoglobin had escaped into the serum, which in the latter case only corresponds to about 25 grms. of blood. The blood readily absorbed oxygen, and became of a bright-red colour, and when exhausted evolved carbonic acid gas. No notable change in the corpuscles was discernible by microscopical examination. In one case the urine contained methæmoglobin, but the quantity only represented 2·14 grms. of blood. From these results there is no evidence that destruction of blood-corpuscles plays any part in producing the general symptoms of burns.

THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

A CONFERENCE has been held between delegates of this Association and of the Hospital Saturday Fund. It is difficult to form an accurate estimate of the plans of the Association. Beyond the idea of a company to float fifty dispensaries in the metropolis, at which the working classes are to be attended on the very lowest terms, we are not favoured with much detail at the meetings. At any rate, such detail is not reported. We caution the promoters against thinking that they can mass the working classes together under the care of a young and untried medical man, to be paid a salary more befitting a clerk than a doctor, which is the method that seems to find favour with them. This will not prevent the members from seeking gratuitous advice at hospitals or dispensaries where men of some standing may be seen; and a scheme such as that proposed should not be encouraged by gentlemen wishing to raise the providence of working men in the extremely important matter of their health and that of their families.

THE CARDIAC CIRCULATION.

L. LANGER has been making observations on the terminations of the small veins of the heart. The minute apertures by which many of them open into the right auricle—foramina Thebesii—are familiar to all, but he has demonstrated similar openings into the left auricle, which Bockdalek had previously discovered. And further, Langer finds that in both ventricles, especially on the papillary muscles, and near the orifice of the pulmonary artery and aorta, are fine apertures smaller than the foramina Thebesii, which he proved communicated with the veins by driving air through them into the veins, and coloured fluids from the veins into the ventricles. The vessels thus opening on to the inner surface of the ventricles are very small, and not the direct branches of the great cardiac veins, and they seem to be devoid of valves. These minute vessels probably serve a useful purpose in equalising the circulation in the heart-substance under its varied conditions.

THE RECORDER AND FALSE STATEMENTS TO REGISTRARS.

THE Recorder, Sir Thomas Chambers, made, the other day, some very curious remarks in reference to the case of a woman named Hyde, who was charged before him with giving a false address of the place of birth of her child in order to avoid having it vaccinated. The woman creditably admitted the offence, her excuse being that a child previously had died, whose death *she attributed* to vaccination. Thereupon the Recorder made the observations which have excited our surprise. He said the whole medical profession were in controversy about the matter—of vaccination, we presume. But what had that to do with the offence of a false statement under the Registration Acts? And even if it had been pertinent it was as inaccurate as anything could be, for there is no one point on which the medical profession is so near unanimity as that of the efficacy of vaccination and revaccination.

ARMY COFFEE TAVERNS.

WE observe with much satisfaction that a coffee tavern for the men of the Guards has just been opened in Buckingham-palace-road, near the Victoria Station. It is intended to be kept open from 5 A.M. till 12 at night, and in addition to providing food and non-alcoholic drinks at very moderate prices, will be amply supplied with newspapers, and rooms will be set apart for reading, writing, bagatelle, &c. It is proposed hereafter to add a library. We wish every success to this laudable endeavour to provide rational amusements for the men of the Guards, and to afford them comfortable accommodation and enjoyment free from the temptation to intemperance which is so abundantly spread before them in the form of magnificent gin palaces.

VARIX OF THE ŒSOPHAGUS.

AMONG the extremely rare positions in which varicose veins may be found is the mucous lining of the œsophagus. An example was exhibited at the Pathological Society by Dr. Bristowe in 1856, in which "the veins of the mucous membrane were found to be enlarged and tortuous, especially in the lower part, having all the characters of varicose veins of the lower extremities." Death was caused by hæmorrhage from the perforation of one of these dilated veins. C. J. Eberth records a closely similar case in *Deutsches*

Archiv f. Klin. Med. A man forty years of age had suffered for four years from hæmatemesis and bloody or tarry stools, and this had been repeated eight times within a year of his death. As there was pain over the region of the stomach, the symptoms were thought to depend upon an ulcer of the stomach. At last a fatal hæmorrhage occurred, and it was then found that the veins of the mucous membrane were varicose over the lower half of the œsophagus, and that, reaching the size of pencils, they projected as soft cords from the surface. The hæmorrhage was traced to an opening in one of these veins, about two centimetres above the cardiac orifice. Several minute white cicatrices were also found along the greater curvature of the stomach.

THE ELECTIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE annual election of Members of Council of the Royal College of Surgeons of England is fixed for Thursday, July 7th. The retiring members are Sir James Paget, Mr. Haynes Walton, and Mr. Wheelhouse of Leeds. The two former gentlemen are expected to offer themselves for re-election; but Mr. Wheelhouse, it is said, will not again seek the suffrages of the Fellows. The following Fellows will be candidates:—Mr. Hulke (1857), Mr. John Croft (1859), Mr. Christopher Heath (1860), and Mr. Reginald Harrison (1866). As the announcement of the day of election appears in the *London Gazette* to-day (Friday), other candidates may be forthcoming, among whom many would be glad to find Mr. George Pollock (1846).

THE STARVATION FOLLY.

AGAIN the American community are to be scandalised by an attempt to fast, this time for forty-five days. Granted the feat is possible, what then? It is a disgrace to the medical profession in the United States that men should be found willing to lend themselves to the grim farce by "watching" it. We are not forgetful of the unhappy fact that the profession in England is discredited by a folly almost amounting to wickedness of the same class. Some years have, however, elapsed since the occurrence of this English scandal, and we may hope our brethren at home have learnt wisdom. We only notice the matter to denounce the whole business. It is useless and mischievous. The procedure is a folly verging on madness, and ought to be so regarded and discountenanced.

A NOVEL and interesting method of adding to the funds of the Chelsea Hospital for Women has been proposed in the shape of a grand fancy fair and musical fête, to be held on June 8th, 9th, and 10th, in the Royal Albert Hall, which will be converted for the occasion into an old English market-place. All the accessories of the fair will be in the old English style, and the device, having been accorded the patronage of Royalty and of a large number of the aristocracy, may be expected to prove a gratifying success.

THE Medical Acts Commission met at 2, Victoria-street, Westminster, on Friday, the 27th, Saturday, the 28th, and Monday, the 30th May. The evidence of Dr. Acland, Sir James Paget, and Mr. Erichsen was taken. There were present: The Earl of Camperdown (Chairman), the Right Hon. W. H. F. Cogan, the Master of the Rolls, Sir William Jenner, Mr. Simon, C.B., Professor Huxley, Dr. McDonnell, Professor Turner, Mr. Bryce, M.P.; and Mr. John White, Secretary.

MR. J. K. BARTON will be elected Vice-President of the Royal College of Surgeons in Ireland on Monday next, the 6th inst.

IT is always pleasant to report the progress of the Coffee Tavern movement. A few days ago the Earl of Onslow opened the Royal Army Coffee Tavern, Stoke, which is a handsome building of three stories, replete with conveniences including stables. The success of this undertaking is much due to the rector of Stoke. But the Earl of Onslow is to be thanked for laying the foundation stone, and for opening the tavern in a speech showing his sympathy with coffee taverns as a means of opposing intemperance.

WE are glad to see that on the recommendation of the Indian Government the Companionship of the Order of the Indian Empire has been conferred on each of the undermentioned officers of the Royal and Indian Medical Services:—Deputy Surgeon-General Norman Chevers, Surgeons-Major Waring, Moorhead, Oliver Barnett, J. Anderson, and Surgeon Owen.

THE Companionship of St. Michael and St. George has been bestowed on Halliday Macartney, M.D., English Secretary to the Chinese Legation.

MR. A. O. M'KELLAR has been elected president, and Dr. M. Long hon. treasurer, of the Queen's University Graduates' Association.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORT OF MEDICAL INSPECTOR OF THE LOCAL GOVERNMENT BOARD.

The Isle of Wight.—Hitherto the Isle of Wight has had to be regarded chiefly from the climatic advantages it derives from its geographical position and from its topographical beauties. Now we are called upon to regard it from the more intimate consideration of its sanitary condition. The Local Government Board has thought it desirable to submit the sanitary administration and condition of the island to a close inquiry, and the result is now before us in the form of a report by Dr. Ballard, one of its most experienced medical inspectors. The contents of this report will, we apprehend, be a matter of painful surprise to tourists, health-seekers, and medical men, in general. It shows that the best interests of the island have been, and continue to be, sacrificed to an incoherent and negligent sanitary administration. It would appear that the sanitary interests of the island are confided to the care of nine separate sanitary authorities, eight of these having charge of the more important urban districts, and the ninth being the authority for the rural district—this district including 86,876 acres of the 93,341 acres which constitute the total area of the island, and about half the total population, the remaining 5465 acres being under the control of the urban sanitary authorities. These several authorities act quite independently of each other, recognise no common interest, display different degrees of activity in the pursuit of their functions, and, in the case of the most extensive district (the rural), the authority even goes out of its way to frustrate the very aim of its existence by an appointment of officers—to wit, nine medical officers of health and four inspectors of nuisance—without any provision for coördinate action, an arrangement which, as might have been anticipated, is fatal to the proper performance of the duties of these officers and to the proper sanitary administration of the district. It is not surprising, therefore, to find that the sanitary condition of the island as a whole, and in view of the great reputation it enjoys among tourists and health-seekers, has been lost sight of in the local interests which concern the several sanitary administrations, and that these again have been dealt with from a contracted point of view, which has been in the highest degree prejudicial to efficient sanitary work. Dr. Ballard, in describing the sanitary state of the various local administrative districts in the island, has to show everywhere serious defects of sewerage or drainage, or water-supply, or of all these matters, with a general prevalence of enteric fever, and in some localities phthisis, which for the future must be seriously considered by visitors, at least, to the island. Writing of West Cowes, Dr. Ballard says: "I gather from the reports of the medical officer of health, and from the conversations I have had with him and with other medical gentlemen practising in Cowes, that for some years past enteric fever has largely prevailed there, not only in the lowest and the poorest part, where the district is (as mentioned before) liable to be flooded from time to time, but in other parts of the town also, and even in the new streets at the highest elevations. No parts of the town and no class of houses appear to have been spared, and visitors who have come there for health have carried away the contagion with them to their homes elsewhere." It is impossible to peruse the report without inferring that this remark is applicable to every part of the island, rural as well as urban. The account given of the pollution of one of the sources of the public water-supply of Sandown is revolting. The sanitary administration of St. Helen's, although lax in several respects, alone seems to deserve a word of approval from Dr. Ballard. No portions of the island appear in less favourable light than Ventnor and the rural district. The reader of this report will be chiefly struck by the evidences of indifference which it furnishes on the part of the sanitary authorities to the intimate sanitary interests of the inhabitants, and of the numerous visitors who flock to the island every year. The only safety from the domestic conditions mischievous to health described by Dr. Ballard, to which visitors are exposed, must rest with the sanitary authorities. If these neglect their duties, or negligently perform them, as they have obviously done, confidence in the island as a health-resort must be eventually destroyed. For people will soon learn to avoid a place where the good to be obtained from a beautiful climate is so very apt to be annulled by bad drainage and sewerage, and a polluted water-supply. Let us hope, however, that this report from Dr. Ballard will arouse the people of the island and the sanitary authorities to a proper sense of the precarious position in which the health-restoring qualities of the island stand, and that we shall presently learn that a more active and intelligent sanitary administration throughout the island has begun. It is painful to find that the most beautiful spot perhaps under British skies should, from lack of foresight of its local authorities, have become reduced in respect to many of the domestic conditions of unwholesome living to a condition which would be discreditable to localities that make no pretensions to be health-resorts.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Middlesex and Hertfordshire Combined Sanitary Districts.—Dr. C. E. Saunders reports a progressive improvement in the health of the combined districts under his supervision, and, as usual, offers much thoughtful advice for the consideration of the sanitary authorities. The death-rate of the combined district, which was 18·6 for the three years 1874–6 inclusive, had fallen to 16·2 for the four years 1877–80. The most noticeable feature in the returns of causes of death was the fatality from summer diarrhœa. Dr. Saunders attributes this to the influence of high temperature, a deficiency of rainfall, and to "filth," exemplified in what he terms, as he tells us "advisedly," "the beastly habits of the people," and the foulness of some, at least, of their surroundings. "It is," he observes, "the influence which filth, in its commonest forms, has on the atmosphere, that it is my greatest desire to see more fully recognised; hence it is with disappointment that I still have to report that so little has been done towards clearing off that abomination—the open privy; and I venture again to ask sanitary authorities to lose no opportunity of enforcing the earth-closet system, which, however badly it may be constructed or kept, and however far it may fall short of what an earth-closet can effect in deodorising excreta, yet in its worst form is incomparably better than the open privy." Dr. Saunders gives some interesting illustrations of the scattering of infectious diseases from the metropolis into the suburban districts, and, equally interesting, of the facility with which such scattering may be prevented from doing mischief if the means of isolation are available.

Withington, Urban (*Lancashire*).—Dr. Railton reports for this district in 1880, among a population estimated at 15,000, a birth-rate of 26·4 per 1000 persons living, and a death-rate of 13·7. Dr. Railton gives careful attention to an exposition of the true principles of house-drainage, illustrating his observations with a diagram; and his remarks deserve the closest attention of the householders in his district.

Glanford Brigg, Rural (*Lincolnshire*).—Mr. James Burdett Moxon reports for 1880 a death-rate of 18·0 per 1000 persons living amongst a population estimated at 29,199. Mr. Moxon's experience of typhoid fever in this district has been such as to confirm, in his opinion, the views of those medical men who believe that the malady is capable of being disseminated by infectious emanations from the sick, and he would enforce the necessity of isolation and the use of disinfectants, as well as means for securing freedom from polluted water, imperfect drains, accumulations of filth, &c. The chief feature of the health history of the year was an excessive infantile mortality. This mortality Mr. Moxon attributes mainly to the imperfect manner in which children are protected from the cold and wet of our climate, and the mode (improper) in which they are nourished, particularly the absence or deficiency of milk in their diet. The difficulty of obtaining milk in parts of his district seems to be great, and he suggests that some of the leading inhabitants should organise measures for the sale of this essential article of diet.

Hexham, Rural (*Northumberland*).—Dr. M'Grigor Maclagan, in his carefully prepared and thoughtful report for 1880, returns a birth-rate of 31·9 per 1000 of the estimated population, and a death-rate of 19·020, being a considerable increase upon the death-rate (17·114) of the previous year. He describes the state of the district with reference to water-supply, drainage, privy accommodation, and dwellings, and shows that while much has been done to amend these matters since the formation of the district, especially as regards privy accommodation, much remains to be done. No special incidence of any of the principal zymotic diseases has to be recorded, but Dr. Maclagan offers some observations upon the difficulty of controlling the spread of infection from the free intercourse maintained among families; and he refers also to one of the notable modes of dissemination of infection in the districts as being determined "by persons who go from house to house selling articles for domestic use, linen and woollen cloth, which is displayed to, and examined by, persons who have been in direct communication with infectious disease, which, after much inspection and handling, is again rolled up and carried to some neighbouring house." He makes the following observations on the same subject:—"Schools, again, have frequently proved the media through which infectious disease has been propagated in the district. Children themselves, recovering from infectious disease, or coming from houses in which disease exists, convey contagion to their schoolmates; and to prevent a further increase of disease in this manner, the closing of schools has been advocated. This is a point, however, which should be left to the discretion of the medical officer, as there can be no doubt that under certain circumstances a greater danger exists of favouring the increase of disease by closing a school than otherwise. When a school composed of children from one village, or who live closely together, is closed, the natural consequence ensues that they are continually invading each other's houses, and thus are brought into closer proximity to disease than when attending school; on the other hand, if a school consists of children from cottages in a sparsely populated and scattered district, some benefit might be derived from its closure."

Maidstone, Urban (*Kent*).—Mr. Algernon Adams reports for 1880 a birth-rate of 31·34, and a death-rate of 18·83 per 1000 population. The healthiness of the district was even greater in 1880 than it was in 1879, although the last-named year is said to have been "remarkably healthy." The utility of the sanitary hospital (although by no means one to be highly commended) was made strikingly manifest in enabling the medical officer to effectually check small-pox in each of four several invasions of that disease. Diarrhœa was the most fatal zymotic disease during the year. Mr. Adams made minute inquiry into the circumstances attending every case of death from the disease, and the conclusions he arrived at were as follows:—"That putrescent changes and improper food are the chief factors in the production of this disease, the changes being set up by high temperature and the miasma which abound in urban districts in the summer season. Starch foods and Swiss milk are bad substitutes for breast milk; experiment and observation have demonstrated that during hot weather putrescent changes are most prone to occur in farinaceous foods, after them in Swiss milk, less so in cow's milk, and least of all in breast milk. When we consider how careless the poor are in cleansing the feeding bottles so universally used it almost amounts to a practical certainty that these deaths from infantile diarrhœa are chiefly due to fermentative and putrescent changes in the improper foods administered. These conclusions lead us to rely for a reduction of infant mortality upon the beneficial results which we may hope to flow from a dissemination of the knowledge that hand-nursing is a dangerous proceeding, especially in the hot season; when, however, hand-feeding is unavoidable the purest and best cow's milk, to the entire avoidance of farinaceous substances, administered by the spoon or scrupulously clean bottles is the only tolerably safe proceeding." Writing of the sanitary condition of Maidstone, Mr. Adams describes improvement in several important respects, but is reserved on the quality of the water-supply, which he says is only "fairly good," and speaks of the hospital accommodation as "dangerously inadequate," a term which indicates that it could have been used with good effect far more largely than it has been had there been more of it and it had been better situated. An interesting separate report on the sewerage of Maidstone accompanies the annual report, also an instructive popular pocket memorandum relating to infectious zymotic diseases.

THE DISPOSAL OF REFUSE.

Few questions have given, and still give, so much trouble to local authorities as the disposal of the house refuse and refuse matters which accumulate among communities. Even when this refuse does not include, as is the case in many localities, excremental matters, and is limited for the most part, as in London, to the contents of ash-bins and market refuse, the difficulty of disposing of it without the creation of nuisance has hitherto been insuperable. And this disposal has to be conducted under circumstances which truly form a stigma upon our civilisation. The local authorities of the metropolis have proved singularly indifferent to the evils arising out of the manner in which the metropolitan refuse has at present to be disposed of, and the ratepayers have had to submit to a chronic poisoning from their dust-holes, which has often provoked the most earnest protests, but with little effect. Of late years there have been certain sickly signs on the part of the local authorities of an awakening sense of the evils to which the inhabitants have been and are subjected from this source, and the most important indication of this awakening must be taken to be the action of the Commissioners of Sewers of the City of London on the subject. They not long ago appointed a committee with certain of their officers to visit sundry northern towns where it was reported some fuller light was being obtained on the question of disposal of refuse, and a report of these proceedings is now before us from the pen of their medical officer of health, Dr. Sedgwick Saunders, which we would fain hope will mark the beginning of a new era in refuse disposal in London. The report is entitled "Some New Methods of Disposing of all kinds of Refuse by Cremation," and it gives a careful account of the disposal of the refuse of communities by fire as practised in several northern towns. "The system alluded to involves two propositions," says Dr. Sedgwick Saunders—"viz.: (1) The destruction by fire of everything combustible in house and trade refuse. 2. The separation of the vegetable from the animal and mineral matters, and its conversion into charcoal." The committee have returned to London wholly in favour of this system; and Dr. Sedgwick Saunders so fully agrees with them that even thus early he contributes to the means for carrying it into effect a design for "a carcase crusher or devil," so that his name will probably in future be intimately associated with the machinery by which the system will be fully carried out. This report of Dr. Sedgwick Saunders is certainly the most important contribution to the literature of the subject that we have yet had. It is admirably illustrated by plans of the "destructors" and "carbonisers," as the furnaces employed are termed, and which owe their origin to the inventive faculty and mechanical genius of Mr. Alfred Fryer of Nottingham. Contrasted with the system of disposal now in operation in the City (of which Dr. Sedgwick Saunders gives a graphic account) it seems almost inevitable, even if the question of decency among a civilised community were alone considered, that the system of cremation must be adopted by the Commissioners of Sewers. If this be done, we have little doubt that an example will be set which other sanitary authorities will be morally compelled to follow, and the metropolis at last relieved from the most disgraceful blot on its sanitary administration. To this good end Dr. Sedgwick Saunders' report is a contribution of the highest importance.

The Sanitary Committee of the Marylebone Vestry congratulates itself in having secured land, *within six miles of the parish*, as a site for a small-pox hospital. This is a curious comment on Dr. Richardson's proposition, that parishes will willingly receive their own sick within their bounds, but object to the sick from other parishes being imposed upon them. The small-pox tent hospital for St. Pancras, which has been opened in the parish of Finchley, as far away from the parish for the use of which it is intended as it is proposed to take the Marylebone hospital, appears to have been fairly used, notwithstanding its distance. Fifty small-pox cases had been admitted up to the 20th ult., and 45 patients were then in the tents.

A proposition to convert the City of London Workhouse at Holloway into a small-pox hospital has given rise to a perfect storm of local opposition. Deputations from the locality have waited both upon the Metropolitan Asylums Board and the Local Government Board to protest against the proposition, and the deputation to the Local Government Board, it is reported, urged that instead of utilising the workhouse, which is situated in the midst of a populous neighbourhood, for the purpose in question, a temporary structure should be erected on some land at Finchley, which is at the disposal of the authorities.

The extraordinary rumour that arose in some parts of the Black Country a short time ago, that three American black doctors were about to visit the Board Schools and forcibly vaccinate the children, has extended to parts of Derbyshire and Yorkshire, and caused as much trouble from the excited mothers as it caused at Dudley and Cosely. At Stonebroom, in Derbyshire, the school was stormed by the mothers of the children, and the teachers were compelled to close it.

We are glad to observe that the Commissioners of Sewers of the City of London are giving attention to the subject of erecting public conveniences for both sexes. The metropolis is scandalously provided in this respect, to the unimaginable misery of numerous persons.

The Warminster Local Board have instructed their Sewerage Committee to form an estimate of the cost of carrying out the scheme recommended by them, and the Central Board is to be asked to sanction the loan necessary to put the drainage into an efficient condition.

A curious case of vaccination by more than twenty punctures is reported from Bridgewater, of which the explanation is not yet forthcoming.

The Birmingham guardians have resolved to employ twenty men to search out all unvaccinated children in the town.

Scarlet fever of a virulent type is reported to be raging at Leicester, and making increasingly extensive demands on the resources of the fever hospital of the town.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a slight further decline last week. In twenty of the largest English towns, the Registrar-General estimates, on the basis of the numbers enumerated on 4th April last, that 7,608,774 persons will be living in the middle of this year; in those towns 5154 births and 2912 deaths were registered last week. The births were 32, and the deaths 345, below the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had been equal to 20·3 and 20·8 in the two preceding weeks, declined last week to 20·0. The lowest rates in the twenty towns last week were 13·9 in Plymouth, 16·9 in Brighton, 17·1 in Bristol, 17·2 in Wolverhampton, and 17·5 in Hull. The rates in the other towns ranged upwards to 22·3 in Manchester, 22·5 in Sheffield, 22·8 in Oldham, and 24·2 in Liverpool. During the first eight weeks of the current quarter the death-rate in the twenty towns averaged 21·2 per 1000, against 23·3, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 396 and 424 in the two previous weeks, further rose to 452 last week; these included 125 from measles, 94 from small-pox, 84 from whooping-cough, 68 from scarlet fever, 42 from fever (principally enteric), 27 from diarrhœa, and 12 from diphtheria. The annual death-rate from these principal zymotic diseases averaged 3·1 per 1000 in the twenty towns, and ranged from 0·0 and 0·7 in Wolverhampton and Plymouth, to 3·5 in Bristol, and 3·8 in London, Liverpool, and Leicester. Measles showed the largest proportional fatality in Liverpool, Bristol, and Sheffield; and scarlet fever in Leicester, Hull, and Bristol. Fever (principally enteric) showed increased fatality in the twenty towns, and caused the highest death-rate in Liverpool. Of the 12 deaths referred to diphtheria 8 occurred in London. Small-pox caused 100 more deaths in London and its outer ring of suburban districts, and 1 each in Brighton and Norwich; no fatal case of this disease was recorded in any of the seventeen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased from 942 to 1390 during the three preceding weeks, further rose to 1552 on Saturday last; of these 538 were accommodated in the tents for convalescents at Darenth. The new cases admitted to these hospitals, which had been 379 and 346 in the two previous weeks, rose to 402 last week. The Highgate Small-pox Hospital contained 84 patients on Saturday last, and 20 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had been 254 and 256 in the two preceding weeks, declined to 241 last week, and were 16 below the corrected average number in the corresponding week of the last ten years; they included 138 from bronchitis and 80 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 3·3 per 1000 in London last week; while the rate from the same diseases was 5·6 in Liverpool and 4·1 in Salford.

The causes of 70, or 2·4 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths in London did not exceed 1·6 per cent., whereas it averaged 3·2 in the nineteen provincial towns. No uncertified deaths were registered last week in Brighton; Portsmouth, Plymouth, Leicester, or Nottingham; whereas the proportions of such deaths were highest in Oldham, Leeds, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half of persons, the annual death-rate last week was equal to 18·4 per 1000, showing a further decline from 21·4, 20·6, and 19·9, the rates prevailing in the three preceding weeks; this rate was 1·6 below the average last week in the aggregate of the twenty large English towns. The rates in these eight Scotch towns ranged from 11·4 and 16·5 in Dundee and Greenock, to 24·4 and 29·2 in Paisley and Perth. The Registrar-General of Scotland has not yet revised his estimates of population in accordance with the recently-enumerated numbers; it is pointed out, however, that the calculated death-rate in Paisley is probably over-stated through an under-estimate of its present population. The deaths referred to the principal zymotic diseases in the eight towns, which had been 82 and 61 in the two preceding weeks, rose to 72 last week; they included 19 from whooping-cough, 18 from diarrhœa, 13 from measles, 11 from scarlet fever, 7 from "fever," 4 rom diphtheria, and not one from small-pox. The annual death-rate from these zymotic diseases averaged 2·8 per 1000 in the eight towns, and was 0·3 below the average rate from the same diseases in the twenty large English towns. This zymotic rate ranged in the eight Scotch towns from 0·6 and 1·3 in Greenock and Dundee, to 3·9 and 4·3 in Perth and Leith. The 19 fatal cases of whooping-cough in the eight towns showed an increase of 3 upon those returned in the previous week, and included 10 in Glasgow, 4 in Edinburgh, 2 in Aberdeen, and 2 in Paisley. The 18 deaths from diarrhœa also reached the number in the previous week, and included 10 in Glasgow and 3 in Dundee; the fatality of diarrhœa was proportionally more than three times greater last week in the Scotch than in the English towns. The 13 deaths from measles reached the numbers in recent weeks; 9 were returned in Glasgow and 4 in Aberdeen. The fatal cases of scarlet fever, which had been 12 and 5 in the two previous weeks, rose again to 11 last week, of which 5 occurred in Glasgow, 4 in Edinburgh, and 2 in Leith. The 7 deaths referred to "fever" (including typhus, enteric, and simple continued) rose within one of the number in the previous week, and included 3 in Glasgow and 2 in Edinburgh. The annual death-rate from this cause in the eight towns was equal to 0·28 per 1000, and was somewhat below the average fever rate in the twenty English towns. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 140, 111, and 96 in the three preceding weeks, further declined to 89 last week, and were equal to an annual rate of 3·5 per 1000; the rate from the same diseases in London did not exceed 3·0.

HEALTH OF DUBLIN.

The rate of mortality showed a further decline in Dublin last week. The annual death-rate in the city, which had been equal to 29·9 and 25·2 in the two preceding weeks, further declined to 24·9 last week; this rate was lower than that recorded in any week since September, 1879. The 159 deaths in Dublin last week showed a further decline of 2 from recent weekly numbers, and included 13, or rather more than 8 per cent., that were referred to the principal zymotic diseases, against 14 in each of the two previous weeks. The 13 deaths from these zymotic diseases included 9 from fever (typhus, enteric, or simple), 2 from scarlet fever, 2 from whooping-cough, and not one either from small-pox, measles, diphtheria, or diarrhœa. The annual death-rate from these zymotic diseases was equal to 2·0 per 1000, while the rate from the same causes was 3·8 in London and 2·7 in Edinburgh. The deaths referred to fever in Dublin, which had been 3, 8, and 7 in the three preceding weeks, rose to 9 last week, and were equal to an annual rate nearly five times as high as the average rate from the same cause in the twenty large English towns. The 2 deaths from whooping-cough corresponded with the number in the previous week, while the 2 fatal cases of scarlet fever showed an increase. The deaths of infants were more numerous than in either of the two previous weeks. Seven inquest cases and 8 deaths from violence were registered during the week.

THE RECENT CENSUS IN THE LARGEST ENGLISH TOWNS.

In his last weekly return the Registrar-General published new estimates of the present population of twenty of the largest English towns, based upon the actual numbers enumerated on the 4th of April last. These new estimates have been substituted for the estimates that had been in use since the beginning of the year, which were calculated on the hypothesis that the rates of increase that prevailed during the ten years 1861–71 would be maintained during the decade just ended. These new estimates of population have a twofold interest—they not only afford the means of comparing the growth of the several towns during the past ten years, but supply a basis for the calculation of trustworthy vital statistics. The hypothetical estimate of the population of the twenty towns was 7,616,417, and was within eight thousand of the new estimate, based upon the recently enumerated numbers. The rate of increase in the aggregate of the twenty towns has been almost identical in the last two decades. In many of the towns, however, very wide differences occur between the two estimates, based respectively on theory and enumeration. The population of registration London is now fixed at 3,814,571 persons, which exceeds by more than a hundred thousand the estimate hitherto in use. This under-estimate of the London population has had the effect of somewhat over-stating its recent rates of mortality, and is due to the fact that the London population has increased at a greater rate during the last than in the preceding decade. The increase of the population of London during the last ten years, by excess of births over deaths, and by aggregation, has been considerably more than half a million of persons; this increase is indeed more than equal to the population of Liverpool, which is the second largest English town. The aggregate population of the nineteen provincial towns is almost identical with that of the metropolis, but as the mean rate of increase in these towns during the past ten years shows a decline from that which prevailed in the preceding decade, the population was over-estimated by more than a hundred thousand. The population of Liverpool is estimated at 552,425, and that of Birmingham at 400,757. Manchester and Leeds are the only other towns with populations exceeding 300,000, while the next largest towns are Sheffield and Bristol, which have populations between two and three hundred thousand. No less than ten of the other towns have populations exceeding a hundred thousand; while the population of the three remaining towns was below that amount. Manchester alone among the twenty towns showed a decline of population (of nearly ten thousand) during the ten years 1871–81. The rate of increase in the other towns ranged from 9·2 and 9·3 per cent. in Plymouth and Norwich, to 28·5 in Leicester, 34·2 in Nottingham, and 41·2 in Salford. Norwich, Birmingham, Nottingham, Liverpool, Salford, and Hull, like London, increased at a greater rate between 1871 and 1881 than in the previous decade. The estimate of the populations of these towns hitherto in use has therefore been somewhat too low, and recent death-rates have been overstated. In the thirteen other towns, however, the rates of increase in the last decade have been lower than in the previous ten years; the estimates of their populations recently in use have therefore been too high, and the death-rates have, as a matter of course, been understated. This understatement of the annual rate of mortality has been largest in Leicester, Sheffield, Salford, and Bradford, and was nearly equal to 2 per 1000 in each of these towns.

HEALTH STATISTICS OF MADEIRA.

An interesting and favourable report on the health and sanitary condition of Madeira during 1880 has recently been published by Dr. Julius Goldschmidt, a medical practitioner of long-standing in the island. The population of the whole island is reported to be 130,473, of which 39,000 reside in the town and suburbs of Funchal. The annual death-rate for the whole island does not exceed 20, and for Funchal 24·4, per 1000. The island is remarkably free from epidemic diseases; and scarlet fever, diphtheria, measles, and whooping-cough are said to be seldom fatal. About six years ago, however, a severe epidemic of small-pox prevailed, which caused about 1000 deaths, which is the less surprising as we are told that there is a general prejudice against vaccination. An excessive fatality from heart disease is attributed to the steepness of the roads, and to the heavy burdens usually carried up and down the hills by the labourers. Considering the general equableness of the temperature, acute diseases of the lungs show considerable fatality; this, however, principally occurs among those living in mountain districts, who in their daily journeys up and down the mountains are exposed to extreme changes of temperature. The population seems to enjoy a remarkable immunity from phthisis, although the social condition of the poorer classes would predispose them to this disease. The foreign residents of the island, who for the most part live under favourable social conditions, are mainly descended from phthisical parents, and yet only one death from consumption is reported to have occurred among this population during the last fifteen years. Entozoa are remarkably prevalent among children, and a considerable number of deaths are referred to the indefinite cause, "febris verminosa." Leprosy too, which is said to have been introduced to the island by the first settlers, still prevails in its southern and western parts; it is estimated that between 400 and 500 persons in the island are affected by this disease, and a special hospital usually contains from seven to fifteen patients. Except for those living in defiance of the simplest hygienic laws, it is evident that Madeira must be classed among the healthiest spots in the world.

THE IRISH CENSUS OF 1881.

Although the alterations in the populations of the Irish towns as compared with the Census of 1871 are not yet accurately known; yet it has been ascertained that in Dublin, Belfast, Londonderry, Newry, and Dundalk the population has increased, and therefore the birth- and death-rates are overstated when calculated according to the returns of 1871. On the other hand, it appears that a decrease has taken place in the populations of Limerick, Waterford, Drogheda, Galway, Clonmel, and some other towns in Ireland.

THE SERVICES.

HEALTH OF OUR TROOPS AT THE GOLD COAST.

A good deal of sickness is reported to exist amongst the troops lately assembled at Cape Coast Castle in view of threatened hostilities with the King of Ashantee. The garrison has been increased by the 2nd West India Regiment from Jamaica, and detachments of the 1st West India Regiment from Sierra Leone; the barrack accommodation at the castle being very limited, the men are distributed in hired houses in the town and in tents, and it is among the former that fevers, dysentery, and diarrhœa are prevalent to a considerable extent. The sickly season at the Gold Coast is close at hand, and we understand Sir Samuel Rowe is anxious to reduce the force to the smallest limits compatible with the existing unsettled state of things in the Colony. The officers are suffering from fever equally with the men, one officer having died, and several having been invalided since the expedition arrived on the Coast.

The death is announced at Queenstown, Ireland, of Surgeon-Major Walter Blake, Army Medical Department. Mr. Blake obtained his commission as an assistant-surgeon in 1864, and was promoted to the rank of surgeon-major in Sept., 1876. His death was due to pneumonia and bronchitis.

The death is reported of Surgeon John Coghlan, late of H.M. 86th Regiment, at Kingstown, on the 28th ult. Deceased was, it is alleged, the oldest medical officer in the service, having recently completed his ninetieth year. He served during the Peninsular War, and retired on half-pay in 1844.

It is stated in the *Broad Arrow* that a fresh inquiry into the cause of the death of Brigade-Surgeon Lundy at Allahabad has been ordered, an analysis having shown that the deceased did not commit suicide by taking poison, as the verdict at the inquest declared.

Deputy Surgeon-General W. J. Moore has been appointed to act as Surgeon-General with the Government of Bombay during the absence of Surgeon-General Beatty, on leave in England.

Surgeon George Stockwell, M.D., has resigned his Commission in the 2nd West Riding of Yorkshire Corps of Artillery Volunteers.

ADMIRALTY. — The following appointments have been made:—Staff Surgeon Richard A. Mowll, M.D., to the *Rocket*, vice Mackie; Surgeon John Mackie, to the *Penguin*, vice Williamson; Surgeon Henry M. Levinge, to the *Flirt;* Surgeon James Hitchcock, M.B., agent at Gamrie, N.B.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Tuesday the Veterinary Surgeons Bill was read a second time.

In the House of Commons on Thursday, May 26th, Mr. Duckham gave notice that on the motion to go into committee on the Lunacy Law Amendment Bill he will move its rejection.

The Case of Captain Butler.

On Friday, Mr. Childers, in reply to Mr. M'Coan, said it was the case that Captain Butler was granted twelve months' sick leave from India, which leave was further extended for six months. He was informed that if at the expiration of that period he was still unfit for service he would be called upon to resign. However, he reported himself sick, and was so found by a medical board, and was accordingly ordered to embark for India. On the day before he should have embarked he sent in a certificate from a civil doctor to the effect that he was unfit to return. He asked, too, for four months' more leave, and upon that he was called upon to retire. There was another reason, of a non-medical character, which made Captain Butler unwilling to return, and that was that he believed he would be arrested for debt as soon as he landed at Bombay. Mr. Childers did not purpose to lay on the table any such return as the hon. gentleman suggested. He did not think it was the wish of the House to interfere with questions of this kind, which were essentially questions for the Commander-in-Chief, subject to an appeal to the Secretary of State.

A petition for alteration of the Lunacy Laws was presented from Limerick. Dr. Lyons has given notice of his intention to move that the Infectious Diseases Notification (Ireland) Bill be referred to a select committee. The Solicitor-General for Ireland and Mr. Meldon have put upon the paper a number of amendments which they propose to move in Committee on the Bill.

Vaccination.

On Monday, Mr. Hopwood asked the President of the Local Government Board whether it was the fact that the matron and one or more nurses at the hospital at Halifax had recently taken small-pox, a few days after revaccination; whether there was any reason to believe the vaccination was of variolous matter; and, whether it was the fact that there was in use in the country a large quantity of vaccine which was in fact variolous matter, or small-pox communicated from the human subject to cattle, and from them extracted and used in inoculation under the Vaccination Acts.—Mr. Dodson replied that the facts of the case were these: At the end of March last a small-pox patient was sent to Halifax Fever Hospital. Thereupon the matron and the nurses were strongly urged to be revaccinated, but they all refused. Three weeks afterwards the matron showed symptoms of the disease, and the day following four of the nurses were vaccinated. One of these had a slight attack of small-pox, which showed itself in two days, and another a more severe attack in four days afterwards. Therefore they must all have been affected by the disease when the vaccination took place, and when the vaccination could be of no avail. The other two nurses escaped altogether. There was no reason to believe that the vaccination was of variolous matter, and the medical man who vaccinated them distinctly stated that it was good vaccine lymph. As to the last part of the question, if variolous matter was intended to mean small-pox, or matter capable of producing small-pox, there was no such matter used in vaccination under the Vaccination Acts. As a matter of fact, he was informed that all attempts of late years to produce small-pox by inoculation of variolous matter appear to have been abortive.

A petition was presented from R. Power for inquiry in connexion with the Indian Army Medical Service. A copy was presented of papers respecting medical officers in India. Mr. Sexton gave notice of a question as to the sanitary accommodation in Kilmainham prison, which he described as insufficient and filthy.

The Local Government Board and the Small-pox Epidemic.

Dr. Cameron gave notice, that on Friday, the 17th inst., on going into Supply, he will call attention to the lack of capacity and resource displayed by the Local Government Board in dealing with the small-pox epidemic at present raging in London; and to move that this House deplores the death and suffering caused by the epidemic of small-pox at present raging in London, and condemns the conduct of the Local Government Board in refusing to take the most obvious means to encourage revaccination, and in witnessing the compulsory closing of small-pox hospital accommodation, when most urgently needed, without attempting to enable adequate provision to be secured for the reception of small-pox patients, thereby leaving hundreds of cases destitute of proper treatment, and sources of infection to densely peopled localities.

Vaccination Prosecution at Warrington.

Mr. P. A. Taylor asked the Secretary of State for the Home Department if he had come to any decision in regard to the fines illegally imposed upon six persons (amounting with costs to 36*s.* 6*d.* each) at Warrington, for refusing to have their children vaccinated, the conviction having been made under the 29th clause of the Vaccination Act, while the children were from three to six years old.—Sir W. Harcourt said the conviction could not be sustained, and he had dirceted the fines to be remitted.

On Thursday, the Attorney-General for Ireland stated that he had received a report, in the absence of Mr. Forster, that the sanitary accommodation at Kilmainham prison was adequate and satisfactory.—Mr. T. P. O'Connor remarked that his information was entirely to the contrary.

The Contagious Diseases Acts.

Mr. Hopwood asked the Secretary of State for the Home Department whether it was the fact that one or more surgeons employed in the compulsory examination of prostitutes under the Contagious Diseases Acts had been made justices of the peace, in order that they might carry out the Acts in a twofold capacity, administering and executing the law; whether he would state by what Minister such gentlemen were recommended to Her Majesty for appointment; whether he approved of such a confusion of duties; and whether the individuals in question should not be called upon to make their choice in respect of those Acts to act either as magistrates or as surgeons only.—Sir W. Harcourt replied that he had no further information on this matter since the hon. member asked the question before. If the hon. member had any ground to think that any of these individuals had been improperly appointed, or had improperly conducted themselves in this matter, and if he would be good enough to state that ground, he (Sir W. Harcourt) would order an inquiry to be made on the subject.—Mr. Hopwood wished to ask the right hon. gentleman if he had not received a letter from him, in which he had mentioned certain persons who were employed in this double capacity, at Devonport, Windsor, and Northampton; and he desired to know whether the right hon. gentleman thought these gentlemen should be allowed in the interests of the public service to continue to discharge double functions.—Sir W. Harcourt said he had no exact information on the subject, but he would inquire what were the facts about these gentlemen.—Subsequently Mr. Carbutt asked if they were to understand that due inquiry would be made in the matter, and if it was found that the gentlemen were acting in a double capacity he would express an opinion that that should not continue, as there was an appeal under the Act for the examining surgeon to the justice of the peace, and they must in that case be the same person.—Sir W. Harcourt said he would make full inquiry into the matter, and the question could then be repeated.

Correspondence.

"Audi alteram partem."

CLINICAL TEACHING AT ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

To the Editor of THE LANCET.

SIR,—As I have had special opportunities of estimating the value of the clinical teaching at Addenbrooke's Hospital, I shall be glad if you will allow me space for a few remarks before the correspondence on the subject is closed.

It is unnecessary to say a word as to the merits of the lecturers of the Cambridge School; their well-known names are a sufficient guarantee of the excellent teaching which is given there. The clinical material, too, to be found in the hospital wards, and especially in the medical wards, will compare most favourably with that at the disposal of the staff of any of our large London hospitals. And yet in many respects the teaching might, I believe, be made more useful. There, as elsewhere, the physician may be found explaining to students, ignorant of the elements of anatomy and physiology, the differential diagnosis of an obscure case of disease. And there, as elsewhere, students may be seen wasting the most precious hours of the morning listening to able clinical lectures, when they were perhaps ignorant of the very name of the disease which the lecturer is illustrating before they entered the class-room. The compulsory attendance on hospital practice and clinical lectures for twelve months prior to passing the Second M.B. Examination is, I know, felt to be a great grievance by many of the hardest working students of the school, and considering that three more years must be so spent before the third M.B. is passed, the time might, I think, with great advantage be reduced to six months. It will scarcely be denied that to attempt to teach physical diagnosis to men ignorant of the mechanism of the heart and the course of the blood-stream is a waste of time on the part of both teacher and taught. Before the student enters the medical wards of a hospital he must at least be acquainted with these elementary facts, if the time there spent is to bring him any return in sound knowledge. I would suggest that students beginning hospital work should be compelled to attend the surgical practice for the first six months, and should not be admitted to the medical wards until they have dissected for at least one winter session, and are acquainted with the anatomy of the thoracic and abdominal viscera. I would also suggest that the visits of the staff to the wards should be made in the afternoon. During the time spent by most men at Cambridge the scientific part of their training is of far greater importance than the purely practical, and to it should be devoted the best working hours of the day. The undergraduate who has no special object in view in his studies may perhaps be right in considering that from three to four hours' reading in the morning constitutes a fair day's work, but it is not unreasonable to ask men who are studying for a profession which embraces such a wide range of subjects as medicine to devote one hour of the afternoon to hospital work.

Cambridge can never provide a complete medical training, but there is no reason why students should not leave there for the London hospitals as thoroughly instructed in the preliminaries of the practical as in the difficulties of the scientific aspect of medicine. The great interest I take in the Cambridge Medical School must be my apology for what may be considered an attempt to instruct my teachers.

I am, Sir, yours truly,
Clarges-street, May, 1881. J. K. FOWLER.

To the Editor of THE LANCET.

SIR,—Your correspondent "Medicus" says the remarks I made about the practical teaching at Addenbrooke's Hospital require some explanation. If I may have unintentionally made it appear that the physicians and surgeons are wanting in zeal, my letter not only requires an explanation, but they require an apology, for it would be hard to find in any one metropolitan hospital more zealous and skilful teachers than Drs. Paget, Latham, Humphry, Bradbury, and Wherry; but, occupied as they are with the cares of large private practices, it is next to impossible for them to spend several hours daily in seeing out-patients, in addition to those in the wards, consequently the "objects of interest" in the wards get the lion's share of the students' attention, to the comparative neglect of that storehouse of useful, but unhappily unused material, the out-patient department, the administration of which is chiefly relegated to the house-physician and surgeon. So that we find the Cambridge medical student towards the close of his career too often strangely deficient in that knowledge which will be required of him a little while hence, and crammed with a catalogue of curious cases, which, like dewdrops upon the grass, will melt and vanish in the heat and burden of the day.

I am, Sir, yours obediently,
May, 1881. A CAMBRIDGE UNDERGRADUATE.

SPONTANEOUS COW-POX.

To the Editor of THE LANCET.

SIR,—As even Dr. Carpenter (who believes in the fundamental identity of vaccinia and variola) now suggests having recourse again to the cow for an entirely new supply of lymph to replace the present deteriorated stock, I presume that there is little doubt that such an attempt will be made on a considerable scale.

The question now arises whether it would be best made with a foreign or native stock. If a foreign stock is selected it is evident that much must be taken upon trust of which the fullest evidence is desirable. My own faith in the virtues of either is limited; but being patriotic, I like to give the preference to the native article, and therefore place at your disposal the information recently sent to me from the county of Elgin, N.B., where it appears the disease vaccinia is by no means extinct, and every year it breaks out in one of the farms. Let me suggest that such lymph be fairly tried, and a record kept of its effects, carefully separating such record from that of persons vaccinated with lymph from other sources. The extreme activity of lymph which has not been humanised by passing through some human beings will always constitute a difficulty when the question of compulsion has to be considered. But the alternative of having to run a risk, now acknowledged by all parties to exist (and which is enough to make the firmest believer shudder), absolutely leaves no option to those who have to administer the law. Animal lymph must be provided for *the whole people*, or the principle of compulsion must be finally abandoned.

I am, Sir, your obedient servant,
EDWARD HAUGHTON, M.D.
Upper Norwood, S.E., May 28th, 1881.

LIVER ABSCESS AND DYSENTERY.

To the Editor of THE LANCET.

SIR,—As the April number of the *Indian Medical Gazette*, just to hand, which contains the closing portion of a lengthy paper of mine on Hepatitis, contains also the matured opinions I arrived at some years ago, as to the relationship between "liver abscess and dysentery" in that country, I extract the same below, and will thank you to insert it in THE LANCET in that connexion by an early date. With this proviso, however, that were I recasting that paragraph again I would word it in a very different and much more emphatic phraseology than it now wears. In other words, instead of admitting reluctantly, as I do within, that this interdependence is "not proven," I should now say that it does not exist, or, if so, however remotely, that the liver "leads the way."

The considerations on which this conclusion is based are too minute or numerous for reproduction here; they are, moreover, so personal to myself, or to the subject under review, that I could scarcely hope to be able to explain them properly without going into details that might appear trivial or irrelevant; and this being so, I would respectfully ask any gentleman who may condescend to notice this little communication to begin any reference he may make to it with the intimation that he has *personally* investigated the matter for himself, as I have done, on the spot, *coram cadavere;* otherwise I will not again recur to the question, for it accords with my experience that Indian observers are just as keen at copying one another in this and other particulars as are their brethren nearer home; and as to the statistics of the case, they are not, in my opinion, worth the paper they are written on.

Discussing then the *locale* of abscess in the liver in India as above, and after stating that, according to my observation, it is more frequently developed in the centre, or rather towards the upper surface, of the right lobe than in any other part of that organ in the North-west and the Punjab, I proceed to say that, such being the case, "it would follow that the abscess would be more likely to eat its way into the chest than into the abdomen; and this too is," I add, "the most usual termination of the two." Then continuing, I say: "Again, this situation would seem to imply a local rather than an eccentric irritation; and I have for many years regarded the interdependence or relationship that is said by some pathologists to exist between bowel disorder and hepatic suppuration as—to use the mildest phrase at my command—not proven."

Though it cannot be denied that "the large intestine does, in the majority of cases of abscess of the liver, present important morbid alterations, especially in tropical countries," yet "are we quite unable to trace any such anatomical continuity of propagation in most cases of hepatic abscess, *while on such a supposition hepatitis ought to be infinitely more frequent than it really is*"; and I most heartily concur with Frerichs when he says, at vol. ii. p. 116, that "*the connexion between intestinal ulceration and hepatitis, as cause and effect, has been by no means established*, although it cannot be denied that in exceptional cases, under favourable circumstances, dysenteric and other forms of ulcerations of the bowels *may possibly* induce phlebitis of the roots of the portal veins, and so give rise to abscess of the liver." The italics are mine, but they are only used to emphasise the more my own willing endorsement of his opinion; and I have looked in vain for the last fifteen years for any or such a confirmation of Budd's views on this point as would induce or oblige me to change my own. I have long harboured an impression, which now amounts almost to a conviction, that no such relationship or interaction exists; and I believe that the contrary opinion has been developed too hastily, or that it is based on a generalisation which a wider field of observation would question or overthrow.

Your obedient servant,
Ashton-under-Lyne, May, 1881. WM. CURRAN.

P.S.—Allow me to add that this paragraph was written five years ago at Sitapur, and to suggest that a circular through the P.M.O.'s office in India, addressed to such senior officers only as had personally tested the point for themselves, would be the best, if not the only effectual, means of acquiring practical information on this moot question.

PUERPERAL MORTALITY IN WORKHOUSES.

To the Editor of THE LANCET.

SIR,—The Local Government Board are collecting statistics upon a subject of interest to obstetricians, and as I append the form with a few additions of my own, I need not explain why I do not know what may be the object of the Local Government Board, but I can see that some useful information may be gathered from the numerous workhouse infirmaries in England which may help in clearing up many moot points in connexion with midwifery. I think this is another score in favour of the value of workhouse infirmaries as a means of solving many of the grave problems which disease opens out (THE LANCET Commission, 1866). A careful analysis of all the facts will show the mortality, class of patients, and the rest, and a comparison may then be made with similar facts obtained from our general lying-in hospitals. Perhaps the Obstetrical Society of London might, on seeing the nature of the facts collected, deem the subject worthy of their attention.

HALIFAX UNION INFIRMARIES.

Returns showing the Number of Births in the Workhouse or Lying-in Wards of the Union, and the Number of Women Confined therein who Died in Childbirth or from causes connected therewith, during the past Ten Years, with other particulars relating thereto.

* Puerperal septicæmia. Full particulars of this case were published in the Obstetrical Journal, November, 1878.

I am, Sir, yours &c.,
T. M. DOLAN, L.R.C.P.E.

May, 1881.

THE DURHAM UNIVERSITY SURGICAL DEGREE.—IS IT M.S. OR C.M.?

To the Editor of THE LANCET.

SIR,—Will you kindly insert the following correspondence, which will speak for itself?

The facts that the Durham University authorities give an extra paper in Surgery to, and require of candidates for their Mastership in Surgery the performance of operations on the dead subject in the presence of the examiners, and consider it an Honours degree, seemed to demand that the matter at issue should be settled by authority.

I am, Sir, very faithfully yours,
W. BARRETT ROUÉ, M.B., M.S. Durh.,
Physician to the Bristol Hospital for Sick Children.

[COPY.]

165, White Ladies-road, Bristol, March 2nd, 1881.

DEAR DR. PHILIPSON,—When I forwarded my qualifications to Messrs. Churchill for their Medical Directory, 1881, I entered M.B., M.S. On consulting the publication I was surprised to find the letters M.S. had been exchanged for C.M.

Again, when I sent notice of a recent appointment to THE LANCET, I used the letters M.B., M.S., and found that the authorities of that paper had also altered the letters M.S. to C.M.

May I ask you, therefore, to send me an official statement in your capacity as Professor of Medicine in the University of Durham as to what letters surgical graduates of the University are entitled to use.

With your permission I intend publishing this letter and your reply in the medical journals.

I am, dear Dr. Philipson, very faithfully yours,
W. BARRETT ROUÉ.

G. H. Philipson, Esq., M.D., F.R.C.P., Professor of Medicine, Durham University.

[COPY.]

7, Eldon-square, Newcastle-upon-Tyne, May 24th, 1881.

DEAR DR. ROUÉ,—I have much pleasure in informing you that the Senate of the University of Durham, at their meeting this day agreed "that Masters in Surgery should be permitted to use the letters M.S. as the abbreviation of the degree."

With very kind regards and every good wish,
I remain, yours faithfully,
(Signed) G. H. PHILIPSON.

W. B. Roué, Esq., M.B., M.S., 165, White Ladies-road, Bristol.

GLASGOW.

(*From our own Correspondent.*)

LAST year a series of papers appeared in the *Glasgow Medical Journal*, written by Dr. F. Henderson, of Helensburgh, on a form of "endemic influenza," which he stated was prevalent in the district in which he lived. This influenza he attributed to effluvia from the polluted water of the Clyde, and from the Glasgow sewage which is carried down the river and deposited on the foreshores of Helensburgh and the Gareloch district generally by the ebb and flow of the tide. This charge was rather a serious one to bring against a favourite seaside resort, "the Brighton of Scotland," and as it cut directly at the source of income of many of the inhabitants, they, through the town commissioners, set themselves to prove that their shores are as clean and their waters as pure as their general surroundings are lovely, and no one can deny that they have succeeded, to their own satisfaction at least. The report of the Commissioners in the matter shows that Dr. Henderson's endemic influenza has no existence in the locality, that the waters of the bay contain less impurity than certain of the London drinking waters, that the "sand" taken from the shore is as pure as that obtained from Lamlash, in the Island of Arran, and that the sewage discharged into Helensburgh bay is "a very mild sewage." The report, in fact, proves far too much. It is undeniable that not so very long ago the waters of this part of the firth were clear and pleasant to look at; but it is well known that for some years impurities have been increasing at such a rate, both in the water and on the shore, that sea-bathing has become a practical impossibility. It is evident that this matter cannot rest where it is; it needs further clearing up. Dr. Henderson's reply to this apparently crushing report is awaited with some curiosity.

Several cases of small-pox have been detected in Glasgow lately. With one exception they were observed among Continental emigrants, who pass through Glasgow for America in such numbers at this season of the year. The appearance of the disease here has put our sanitary authorities on the alert, and it is now arranged that emigrants passing through Scotland shall be examined at the port of debarkation, so that persons presenting signs of small-pox shall be prevented carrying it further.

Obituary.

WILLIAM DONALD NAPIER.

It is our painful duty to record the sudden decease of Mr. William Donald Napier, a gentleman who has for many years occupied a high position in the profession. At an early period of his career he devoted his attention to the special study of dental surgery, and nearly thirty years ago commenced to practise that branch of surgical work, and continued to do so with marked success until his decease, which happened, somewhat suddenly, on Thursday, the 26th ult. He had been in delicate health for some time past, but by relaxation from the more arduous duties of practice his friends hoped that he might survive for many years. Mr. Napier was a member of the Royal College of Surgeons, and a Fellow of several of the Medical Societies. He took a very keen interest in the ethics of the profession, and was most earnest in maintaining the privileges of surgeons who, like himself, have devoted their lives to the special practice of dental surgery. The services he rendered, almost single-handed, to the surgical profession, as distinguished from the outlying class of "dentists" who are not surgeons, cannot be soon forgotten, and should not remain unacknowledged by the general body of medical practitioners, or the Association of Surgeons Practising Dentistry, whose honour he stoutly upheld. Mr. Napier was a man of most elegant taste, and in private life an affectionate and kind friend.

COOMBE LYING-IN HOSPITAL, DUBLIN.—The fifty-third annual meeting of the subscribers to this hospital was held last week; and from the annual report we learn that the income for the year ending March 31st last amounted to £1502, being a decrease of £264 as compared with the previous year, while the expenditure was £1755. The Board trust that the necessary help will be forthcoming to enable them to clear off the debt of £1043 they have incurred. This necessity is greater than ever, owing to the closing of the maternity department of Steevens' Hospital, so that the entire district now depends upon the Coombe Lying-in Hospital for the care of those requiring aid in labour. The Board have appointed Dr. Samuel Gordon, Ex-president of the College of Physicians, a consulting physician in the room of the late Dr. Alfred Hudson; while the vacant assistant-mastership has been filled by the appointment of Dr. Poole, who, with Dr. Neville, resides in the hospital. We understand that since the annual meeting was held special subscriptions amounting to £259 have been received.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Part of the Professional Examination for the Fellowship at a meeting of the Board of Examiners on the 26th ult.:—

John B. Sutton, Middlesex Hospital; Frederick Deighton, Cambridge and St. George's Hospital; Bertram H. L. Stivens, King's College; Alfred Lingard, St. Thomas's Hospital; Richd. F. Rand, Edinburgh and Glasgow; Arthur B. Prowse, Liverpool and St. Mary's Hospital; Percy Edgelow, St. George's Hospital; William R. Buckell, University College; James Wilson, Belfast.

Of the 98 candidates who were admitted for examination during last week, 57, or over 58 per cent., failed to satisfy the Board of Examiners, and were referred for six months' further anatomical and physiological study.

The Final Examination for the Fellowship was brought to a close on Monday last. Of the 27 candidates examined 10, or 37 per cent., were rejected. We shall publish the list of names next week. At the corresponding period last year there were only 68 candidates examined, of which number 31, or 45·5 per cent., were rejected.

[In the list of Members published in our last, for "Joseph Wilmot Buxton" read "Dudley Wilmot Buxton."]

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on May 26th:—

Douty, Joel Harrington, Middlesex Hospital.
Goddard, Walter Horace, Norfolk-crescent.
Greene, Henry, Norfolk-crescent.
Odling, Alfred Edward, St. Thomas's Hospital.
Ranson, William Edward, Alfred-place.

The following gentleman also on the same day passed the Primary Professional Examination:—

Augustus Frederick Clay, General Hospital, Birmingham.

THE power of granting degrees in medicine, as well as in laws, science, and music, has been granted to the University of Adelaide, South Australia.

THE JACKSONIAN PRIZE.—The subject of this prize for the ensuing year is "Wounds and other Injuries of Nerves, their Symptoms, Pathology, and Treatment." For the present year, it is the "Pathology and Surgical Treatment of Diseases of the Hip-joint."

ROYAL HOSPITAL FOR INCURABLES.—The day of the opening of the new wing of the Royal Hospital for Incurables by the Duke of Connaught, originally fixed for the 9th of July, has been altered to the 16th in consequence of the Royal Volunteer review at Windsor being ordered for the 9th.

PROFESSOR GERALD YEO will commence his course of three lectures "On the Application of the Graphic Method to the Study of Muscle Contraction," in the theatre of the Royal College of Surgeons, on Monday next, the 6th inst.: the first lecture, on the "Phases and Varieties of a Single Contraction;" Lecture 2, "The Summation of Contractions and Tetanus;" and Lecture 3, "On Fatigue and Recuperation."

EAST LONDON HOSPITAL FOR CHILDREN.—The fourteenth annual meeting of the governors of this useful charity was held this week. The receipts during the past year were £11,313, being an increase of £4959 over those of 1879-80. The expenditure amounted to £6007. It is intended to apply the balance to the work of building and furnishing the third storey, and to the enlargement of the out-patient department.

AT the seventy-fourth annual festival of the London Truss Society, held on the 27th ult. at the Albion Tavern, and over which Mr. Sheriff Waterlow presided, it was stated that during the past year more than 9000 persons had received the benefits of the charity, a number exceeding by 561 that of any previous year, and since its foundation 369,515 people had been relieved by the society. Donations and subscriptions to the amount of £600 were announced at the meeting.

RECENTLY Dr. Baird of Perth, who appears to have been for some time indisposed by illness, was waited upon by a deputation composed of leading citizens of Perth, and presented with a purse of 200 guineas, accompanied by an expression of the esteem in which he was held, and of sympathy with him in his affliction.

UNIVERSITY COLLEGE HOSPITAL.—At University College, on Wednesday afternoon, Mr. Justice Fry presiding, Mr. Justice Watkin Williams distributed the medals and prize certificates to the successful students in the medical faculty. The gold medals were awarded in anatomy, to E. Hudson; in physiology, to W. A. Gostling; in chemistry, to P. Mukerji; in medicine, to W. C. Wilkinson; in surgery, to C. Stonham; in zoology and comparative anatomy, to A. E. Tovey; and in clinical medicine, to C. Stonham. Afterwards Mr. Justice Watkin Williams briefly addressed the students.

BROMPTON CONSUMPTION HOSPITAL. — By the report read at the annual court of governors of this charity, held last week, it appears that during the year 1880 the number of patients admitted was fifty-four in excess of that of the previous twelvemonth. Of the total number of admissions (904), and of those remaining at the end of 1879 (185), there were discharged greatly benefited 795, and 102 deaths. The new extensive building, to contain 137 additional beds, was nearly completed, and payments on account of the contracts to the amount of £51,673 had already been made.

LONDON HOSPITAL MEDICAL SCHOOL.—The following is a list of the results of the late scholarship examinations:—Clinical Medicine: Mr. J. A. Williams, Mr. Harris (honorary certificate), Mr. Adkins (honorary certificate). Clinical Surgery: Mr. J. A. Williams. Duckworth Nelson Prize: Mr. J. A. Williams, Mr. Russell (honorary certificate). Anatomy Scholarship: Mr. Allden, Mr. J. Thomas (honorary certificate), Mr. Langston (honorary certificate). Anatomy, Physiology, and Chemistry Scholarship: Mr. F. H. Taylor, Mr. Gordon (honorary certificate). Out-patient Dressers' Prizes: Mr. Nicholson, £15; Mr. F. H. Taylor, £15; Mr. Blaxland, £10.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION. The fifth annual meeting of the above Association was held on Friday, May 27th, at the rooms of the Medical Society of London, under the presidency of Dr. B. W. Richardson. The report stated that the number of members had increased to 250 and of associates to sixteen, the latter being medical students, and alluded to the fact that there are known to be many more abstaining medical men at present unconnected with the association. The accounts were presented, and showed a balance in hand of £9 0*s.* 6*d.* The re-elected officers having been installed, S. S. Alford, Esq., read a paper on "The Practical Treatment of Dipsomania." A warm discussion followed, which was adjourned till that day month.

BOOKS ETC. RECEIVED.

BAILLIÈRE ET FILS, Paris.

L'Œuvre de Claude Bernard. Introduction par Mathias Duval; Notices par E. Renan, Paul Bert, et Armand Moreau; Table Alphabetique par le Dr. Roger de la Coudraie; Bibliographie des Travaux Scientifiques, etc., par G. Malloizel. pp. 384, avec un Portrait.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the lates*

BAKER, J. B., L.R.C.P., M.R.C S.E., has been appointed House-Physician to Charing-cross Hospital.

BARR, J., L.R.C P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Towcester Union, vice Floyer, resigned.

BELLINGHAM, J., M.R.C.S.E., has been appointed Medical Officer to the North District of the Dudley Union.

BOOTH, L., M.D., M.R.C.S.E., &c., has been elected Medical Officer of Sherburn Hospital, near Durham, vice R. W. Gillespie, resigned.

CANNING, P. W. G., R.N., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident House-Surgeon to the Hull and Sculcoates Dispensary.

FRASER, T., M.B., L.R.C.P.Ed., has been appointed Medical Officer to the Workhouse of the Berwick-on-Tweed Union, vice Brown, resigned.

GORDON, S., M.D., has been appointed Consulting Physician to the Coombe Lying-in Hospital, vice Hudson, deceased.

GRINDON, F. J., L.S.A.L., has been appointed Resident Obststrical Officer to Charing-cross Hospital.

JULER, H. E., M.B., F.R.C.S E., has been appointed Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

KILNER, C. S., M.B., C.M., has been appointed Medical Officer to the Workhouse of the Thingoe Union, vice Wing, resigned.

LEWIS, W. A. A., L.R.C.P. & L.R.C.S., has been appointed Surgeon to the Oswestry Cottage Hospital and Oswestry Dispensary, vice J. S. Davies, M.R.C S.E. & L.S.A.L., deceased.

LYSTER, Mr. C. R. C., has been appointed Assistant House-Physician to Charing-cross Hospital.

MOSSE, Mr. H. R., has been appointed Assistant House-Surgeon to Charing-cross Hospital.

PARKER, G. R., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Southern District of the Lancaster Union.

POOLE, W. C., M.B., L.R.C.S.I., has been appointed Assistant Master of the Coombe Lying-in Hospital.

ROBERTSON, J., M.D., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Cockermouth Rural Sanitary District.

SPENDER, T. K., M.D., M.R.C.S.E., L.S.A.L., has been appointed Physician to the Bath Mineral Water Hospital, vice Falconer, deceased.

STAFFORD, T. E., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Maxey District of the Peterborough Union.

TAYLOR, F. E., M.R.C.S.E., has been appointed House-Surgeon to Charing-cross Hospital.

VALLANCE, T. J., M D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Schools of the West Ham Union.

WOODHEAD, G. S., M.B., M.R.C.P.Ed., has been appointed Demonstrator of Pathology and Assistant to the Professor of Pathology in the University of Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

ARMSTRONG.—On the 20th ult., at Rodney-street, Liverpool, the wife of James Armstrong, M.B., of a son.

BATEMAN.—On the 27th ult., at Whitchurch, Oxon, the wife of Francis Bateman, M.B., of a son.

LORD.—On the 25th ult., at Wilton House, Landport-terrace, Southsea, the wife of Frederick Lord, L.R.C.P.Ed., L.R.C.S.Ed., of a son.

NICHOLLS.—On the 2nd ult., at Dominica, West Indies, the wife of H. A. Alford Nicholls, M.D., of a daughter.

POIGNAND.—On the 23rd ult., at Upper-street, Islington, the wife of Malcolm Poignand, M.D., of a son.

STEVENSON.—On the 27th ult., at Sandhurst Lodge, Gresham-road, S.W., the wife of Thomas Stevenson, M.D., F.R.C.P., of a daughter.

MARRIAGES.

BRUCE—PARKER.—On the 1st inst., at St. Mark's, Sheffield, the Rev Canon Bruce, Rector of Carlton, Worksop, to Ann, widow of the late Samuel Parker, F.R.C.S., of Broomgrove Cottage, Sheffield.

GOSS—SLADE.—On the 25th ult., at St. Swithin's Church, Walcot, Bath, Tregenna Biddulph Goss, of Bath, Surgeon, to Aimée, daughter of the late Edward Slade, of Calcutta, and adopted daughter of James Slade, of Kensington-place, Bath.

DEATHS.

HILLIARD.—On the 21st ult., at The Vicarage, Tettenhall Wood, near Wolverhampton, George Richard Hilliard, M.R.C.P.L., formerly of Rayleigh and Chelmsford, Essex, in his 81st year.

HUTTON.—On the 27th ult., at 240, City-road, Edith Annie, the dearly-loved child of Robert J. and Kate Hutton, aged 9 months.

NAPIER.—On the 26th ult., suddenly, at George-street, Hanover-square, W., Donald Napier, M.R.C.S.E., aged 50.

RADFORD.—On the 29th ult., at Higher Broughton, Thomas Radford, M.D., F.R.C.P.Ed., aged 88.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, June 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

Tuesday, June 7.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor H. Morley, "On Thomas Carlyle."

Wednesday, June 8.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Professor M. Duncan, "On some Unusual Developments of the Axial Canals of Sponge Spicules and their Meaning."

Thursday, June 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Professor C. E. Turner, "On Russian Literature: Tourgenieff.

Friday, June 10.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—8 P.M. Professor Dewar, "On Origin and Identity of Spectra."

Saturday, June 11.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor C. E. Turner, "On Russian Literature: Nekrasoff.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following are the written questions asked on the 26th ult. at the final examination for the Fellowship:—

1. Describe the anatomy of dermoid cysts, and discuss the question of their mode of origin. In what regions are they usually found, what symptoms do they produce in each region, and what treatment should be adopted?
2. In a case of aneurism at the root of the neck, on the right side, what circumstances would aid you in fixing its seat? What methods of treatment are applicable, and what would influence your selection of each method?
3. Mention the nerve-trunks of the upper extremity which are especially liable to be injured in accidents, and give the symptoms which would result in each if the nerve concerned were completely divided.
4. Describe the various risks encountered by a patient who has undergone the operation of lithotomy; state the best means of their prevention, and the treatment to be adopted in each complication.

There were twenty-seven candidates, of whom ten were rejected. At the corresponding examination last year there were nineteen candidates, of whom eight were rejected.

"TEMPERANCE AND THE DOCTORS."

AN account from the *Western Gazette* has been sent us of a speech delivered by Mr. Alfred Crespi, at Yeovil, on the medical bearings of alcohol. Mr. Crespi's speech was rather an attack on doctors than on drink. He pointed out that doctors were such gentlemen that his own social status had rather been lowered than otherwise by entering the profession, and that medical men sought rather to please their patients than to form an independent judgment, to which indeed, from their low origin in the lower middle class, they were incompetent. We are sorry to have to add that neither the vicar, who presided, nor Dr. Ridge, who followed Mr. Crespi, took exception to these remarks, which seem as ungrateful for all that has been done by the profession for temperance of late years as they are unjust. But the profession must feel thankful to Mr. Crespi for at least abating its lowliness by coming into it and so far lifting it up, and, further, for the light thrown by his speech on the habits of the upper classes with whom he mixed *before* he stooped to enter the medical profession.

St. B. (Belvidere).—The case was reported in THE LANCET of April 9th last.

TIGHT-LACING.

To the Editor of THE LANCET.

SIR,—In 1861, when I was Mr. Skey's house-surgeon, a woman, aged fifty-three, was brought in a state of collapse to St. Bartholomew's Hospital with strangulated femoral hernia on the right side of four days' duration. The protrusion was returned by the usual operation, but the patient died. On examination it was seen that the part strangulated had been the tip of the gall-bladder. The lower part of the thorax was very narrow and so elongated that the end of the last rib touched the crest of the ilium; the liver, deeply furrowed by the ribs, reached far into the iliac fossa; and the gall-bladder, which was filled with gall-stones, protruded nearly four inches beyond the edge of the liver. The patient, her sister told me, had been for many years a noted tight-lacer. I hope this case, in which the gall-bladder was forced out of the abdomen into the thigh by tight-lacing, may help you to expose the dangers of this practice.—I am, Sir, yours, &c.,

May 31st, 1881. HOWARD MARSH.

DRUG-SELLING AND DISPENSING IN BENGAL.

THE amended Municipal Bill for Calcutta, recently passed by the Bengal Legislative Council, deals, amongst other things, with certain abuses which have hitherto existed in the drug trade in that province. Now (says the *Indian Medical Gazette*) mouldy extracts and pill masses, worm-eaten roots and effete tinctures can be seized and confiscated, and vendors punished for attempting to palm off trash on the public instead of physic. Formerly drug-shops were indeed subject to registration, but no conditions were imposed with this object. Any man could open a drug-shop, whether he possessed any knowledge of drugs himself or employed a competent or an incompetent assistant. Now the owner of a drug-shop is compelled to employ a man whose knowledge of drugs has been tested and certified. And no dispensary where European drugs are kept and compounded can be registered unless a qualified compounder is engaged.

Ethnologist.—The "Barnard Davis Collection" was purchased by a special vote of the Council of the Royal College of Surgeons, at an expense of £1000, and has been added to the museum of that College. It contains nearly 2000 specimens, nearly all well authenticated and catalogued.

SILVERLOCK'S MEDICAL REFERENCE BOOK.

To the Editor of THE LANCET.

SIR,—Referring to the notice of the above, we write to inform you that Mr. George Brown did not furnish the list of consultants complained of in your journal. That information was volunteered by a member of the profession at the time when the work, as edited by Mr. George Brown, was in hand, and was then accepted as an addition to the work.

We wish to call attention to the fact (which does not appear to be generally noticed) that the list is made out on a principle, "authors on special subjects only," as notified at the beginning. Whether wisely or not, we do not pretend to have any opinion.

We can only wish the author had made a happier list.

I am, Sir, yours faithfully,

June 1st, 1881. Pro H. SILVERLOCK, C. W. H.

To the Editor of THE LANCET.

SIR,—I shall feel obliged if you will kindly permit me to state that the "List of Consultants," published in Silverlock's Medical Reference Book, was inserted in that work (notwithstanding my name appears on the title-page as editor of the same) without my knowledge or consent. That my name should have been connected with anything so obviously calculated to cause offence to the profession generally has been to me a source of great annoyance.—I am, Sir, yours faithfully,

Gibson-square, Islington, N., May 24th, 1881. GEORGE BROWN.

DESQUAMATION AFTER DRUGS AND AFTER SCARLATINA.

To the Editor of THE LANCET.

SIR,—The observations we have made in this hospital with regard to desquamation may briefly be summarised thus: The more intense the rash, the quicker the peeling of the skin. Very slight cases, when the rash is only visible for a few hours, are usually a long time in completely desquamating, and in many of these cases it is sometimes deferred for some weeks, so that we have occasionally been on the point of discharging a patient when the first signs of desquamation have been discovered. Peeling is usually first seen in the folds of the neck and on the forehead and face, whilst yet the rash is fully out on the lower extremities and body. The last parts to get rid of their old skin are the feet, and particularly the heels. In several cases, with intensely bright scarlet rash and high temperature, the desquamation has been complete in thirty days; the great majority, however, take from sixty to seventy days before we consider them fit for discharge, although they may have been perfectly well for weeks. In many cases it has been extremely doubtful whether, after nine weeks' quarantine, the old thick skin has been completely shed from the heels.

The dead skin from scarlatina patients no doubt carries infection, but there must be some other factor at work sometimes, for on several occasions we have kept patients here for eight weeks, bathing them almost daily. The hair has been cut short, and the head frequently washed with a carbolic acid lotion (one part in twelve). Desquamation has been observed to be complete. New clothes have been brought, the patient taken from a bath, dressed in them, and at once taken home, when it has occurred that children of the same family have caught the fever in something like a week after their relative's return. Desquamation frequently takes place during the progress of enteric fever, but, so far as I have seen, the feet and hands have not peeled except in the cases of labouring men, and this I have observed in the same class when laid up for some time with a fractured leg, or other injury keeping them from their usual work. Out of nine hundred cases of scarlatina I do not remember to have seen one where desquamation at some period or another has not taken place. A young lady is in hospital now who, sixty-four days since, was admitted with slight rash and sore-throat, and from whose feet flakes of dead skin can now be peeled.

I am, Sir, yours, &c.,

Fever Hospital, Bradford, May, 1881. W. R. RIX.

BOY-SMOKERS.

WHATEVER difference of opinion there may be amongst members of the medical profession as to the effects of the moderate use of tobacco by adults, the discussion in our columns at the commencement of the year 1880 of the subject of smoking revealed a pretty general agreement in the conclusion that the employment of the narcotic weed by persons of immature years was wholly and distinctly detrimental. Some time ago a law was passed in Germany to prohibit the use of tobacco by boys under fifteen, either at home or in the streets. Several of the Swiss cantons have now, it is stated, followed the example of their big neighbour, and made it illegal for youths to indulge in the deleterious habit. Half an hour's stroll in the streets of London is sufficient to engender in the peregrinator a wish that something could be done in this country to check the consumption of tobacco by little boys whose mouths are more fitted to receive a stick of barley-sugar than a short black pipe.

DOMESTIC REGISTERS OF HEALTH.

To the Editor of THE LANCET.

SIR,—The prevalence of small-pox, the necessity that exists for revaccination, and the uncertain data one derives from persons desirous of knowing whether it is or is not necessary to be revaccinated, lead me to make public a suggestion I have often made in private practice—namely, that parents should provide for their children a record-sheet showing when vaccination and revaccination had been performed, successfully or otherwise, and that this sheet should be amplified by short notes of the illnesses which occur in after-life, verified when practicable by the medical man in attendance.—I am, Sir, yours, &c.,

Hogarth-road, May 25th, 1881. CHARLES PRIDHAM.

HYPODERMIC INJECTION OF MORPHIA.

To the Editor of THE LANCET.

SIR,—Will any of your numerous readers kindly inform me how best to ward off the sickness so often following the subcutaneous injection of morphia. I have at present a patient suffering from severe and long-continued intercostal neuralgia, to whom the morphia affords great relief, but distressing sickness invariably comes on soon after its administration, and lasts for several hours. I have tried adding a small quantity of atropine, but this has not been followed by any good results. I will be very much obliged for any information on this point.

I remain, Sir, yours truly,

May 23rd, 1881. J.

"A PRACTICAL PHASE OF THE LUNACY QUESTION."

To the Editor of THE LANCET.

SIR,—Medical officers of asylums will probably not be disposed to find much fault with your article of May 7th (page 749), except with that portion of it which appears to underrate the value of their therapeutic efforts.

You say "there is practically no such thing as treatment now-a-days," but you admit that the patient is placed "under what are deemed to be favourable circumstances, amid pleasant surroundings," that "drugs are given to produce quiet, to relieve pain," &c., and that "the effect of such drugs as come recommended to the notice of the asylum physicians of England, from the Continent and the United States," is investigated. Surely, Sir, this is doing something in the way of treatment. In general medicine, is not the position of our most scientific physicians with regard to drugs (except in the case of some half dozen so-called "specifics,") one of enlightened scepticism, and their mode of treatment in most cases "expectant," endeavouring to remove all obstacles in the way to recovery, and lending a helping hand to the natural powers as occasion may offer?

Again, you say "there is little or nothing personal in the treatment." This may unfortunately be true, to a certain extent, of the "chronic" or "incurable" cases, owing to the vast numbers which have to be dealt with in our public asylums, but as regards the "acute" or "curable" cases it certainly is not the fact. As you say, five per cent. may be taken as the proportion which the curable cases bear to the total number of patients in any given public asylum. On this computation the number of curable cases a superintendent of even the largest asylum could have under his care at any one time would be from forty to sixty, a number to which he is well able to give individual attention, and the observation and treatment of these cases is, to every medical officer worthy of the name, an affair of the deepest interest.

The experiment of establishing lunatic hospitals, to which all curable cases should, in the first instance, be sent, is no doubt worth trying; but from the fact that the best of the existing hospitals do not obtain much better results than good public asylums, when due allowance is made for the different class of patients admitted, it would be well not to be too sanguine in our expectations.

In conclusion, a word with regard to the letter of an "Ex-superintendent" in your last number. He is much exercised on account of the want of professional ability displayed by asylum medical officers, and then goes on to suggest a reform which he admits would necessitate smaller salaries. To be consistent he should advocate the abolition of salaries altogether, then he might succeed in attracting men of even "leading ability" to the study of lunacy. I imagine that the public would be only too delighted if all the public services could be improved in this easy and economical manner.

I am, Sir, your obedient servant,

M.B.

TRAINING SHIPS.

AT the conference of managers of reformatories and industrial schools, held this week at Bristol, Captain Nicholetts, R.N., offered some important observations on training ships. It was not to be expected perhaps that the speaker should make any prominent reference to the hygienic state of those vessels; indeed, he seems to have altogether ignored this branch of the subject. Yet in any complete description of training ships the consideration of their condition from a sanitary point of view must necessarily be included. We have on more than one occasion (see THE LANCET for April 24th and June 5th, 1880) expressed our opinion on this point, and would take the present opportunity of enforcing the need of precautions in the direction indicated in the articles to which we have referred.

Mr. K. G. Ault.—We cannot say. The gentleman may be the holder of a foreign degree.

Messrs. Lambert and Morrison.—The subject is under consideration.

Mr. T. Smith Rowe.—The institutions are numerous. The Classified Directory to the Metropolitan Charities (published by Longmans and Co.) contains a full list of them.

A Physician.—None but a graduate in the degree of "Doctor" can legally call himself by the title.

CONCURRENT VARIOLA AND VACCINIA.

To the Editor of THE LANCET.

SIR,—Under the above heading "In Perplexity" records the early stage of a very interesting case. My note-book furnishes two somewhat analogous, though not such severe cases, which may also interest your readers.

Case 1. On April 8th, 1881, a young lady sickened with small-pox, and on the 12th was removed to a private hospital on account of the family. During the four days she was nursed by her mother. On the 12th the mother was revaccinated successfully in four places; the rooms, bedding, &c., disinfected.—25th: She now sickened.—26th: Temp. 104° F., with a discrete eruption out. Although the vesicles were few, the erythematous blush around each was much larger than I have usually seen in slight cases. The other features were the intense headache from the onset, and all through its course for the next fourteen days. The headache cleared off, and then for the next four days severe facial neuralgia existed. The vesicles crusted about the seventh day, and rapidly fell off. She is small, spare, and not of a particularly nervous temperament. She has made a good recovery.

Case 2. That of a servant girl aged sixteen, strong and robust. A young lady had been removed from the house eight or nine weeks before, had made a good recovery and returned. About a week after her return the girl was revaccinated, and successfully, in three places. Fourteen days after revaccination she sickened with small-pox of an extremely mild type. She made a good recovery. I do not suppose that she contracted the disease from the young lady in any way, as she had been known to have been visiting in an infected district.

I am, Sir, yours, &c.,

May 28th, 1881. L.R.C.P.E. & S.E.

"LICENSING BODIES AND THEIR DIPLOMAS."

To the Editor of THE LANCET.

SIR,—I think a law ought to be passed compelling the assigns of deceased medical men to deliver up the diplomas within a reasonable time after death, so as to prevent the selling of them to others, as I fear it could be easily proved that the diplomas and brass plates of deceased men are used by those who can get hold of them.

I am, Sir, yours faithfully,

May 30th, 1881. G. D. HARDING, M.R.C.S., &c.

THE BITES OF INSECTS.

JUST now, when a sudden, though probably brief, visitation of fine and warm summer weather entails a small plague of flies and insects, it is well to remember that the prompt application of an alkali to the bitten part allays the irritation and commonly at once relieves the suffering consequent on a class of injuries which, though small, are often exceedingly annoying and even troublesome, especially in the case of children and persons with sensitive skins. Soda and ammonia will answer the purpose.

UTERINE DILATORS.

To the Editor of THE LANCET.

SIR,—With reference to the letter from Messrs. Mayer and Meltzer (in THE LANCET of Saturday last), into which they import the name of my friend and senior colleague, Dr. Chambers, I am enabled to state on his authority that he did not obtain the uterine dilator from that firm until after I had shown a working example of my own instrument at the Chelsea Hospital for Women by Messrs. Maw, Son, and Thompson. *Suum cuique.*—I am, Sir, your obedient servant,

Thurloe-square, S.W., May 23rd, 1881. JOHN JAMES, M.B. Lond.

"THE BLOOD OF SAINT JANUARIUS."

To the Editor of THE LANCET.

SIR,—In your last issue Mr. A. Clarence Foster asks if this miracle has ever been submitted to the ordeal of unbiased scientific inquiry. In reply I beg to say that the ecclesiastical authorities at Naples have preserved a document from Sir Humphry Davy, asserting that he knew of nothing in chemistry or nature which could account for what he had witnessed. He was present at the "miracle" in 1818, when he went to examine the manuscripts of Herculaneum. Your correspondent will find more information on this subject in the "Manchester Dialogues," first series, by the Rev. Thomas Harper, of Stoneyhurst College (London: Burns and Oates, Portman-street, W.).—I am, Sir, yours obediently,

May 28th, 1881. F. E. C.

THE NATIONAL VACCINE ESTABLISHMENT AND ITS LYMPH.

To the Editor of THE LANCET.

SIR,—I have noticed a letter in your last issue drawing attention to the frequent uselessness of the lymph supplied by the National Vaccine Establishment. My father, who is a public vaccinator, has usually made the same complaint; indeed he resorts to the National Vaccine Establishment as little as possible, and never with any confidence.

I am, Sir, yours, &c.,

May 17th, 1881. A READER OF THE LANCET.

To the Editor of THE LANCET.

SIR,—In answer to "A Public Vaccinator," I beg to state that I have been disappointed in every case that I have vaccinated with the lymph supplied by the National Vaccine Establishment. This has on one occasion caused much inconvenience and delay, as I had to procure better lymph from the wholesale chemists that I deal with.

I am, Sir, yours, &c.,

May, 1881. ANOTHER PUBLIC VACCINATOR.

To the Editor of THE LANCET.

SIR,—I lately obtained a supply of vaccine from the above establishment with which I vaccinated three adults, two of whom succeeded admirably, and one failed, this latter due no doubt to insusceptibility on the part of the patient.—I am, Sir, yours faithfully,

London, May 28th, 1881. T. d'O. PARTRIDGE.

To the Editor of THE LANCET.

SIR,—During the last twenty years I have been supplied with lymph from the above-named institution upon certainly more than one hundred occasions, and have always found it efficacious. Several of my medical friends have been supplied in the same way, and upon no occasion have I heard them complain.—I am, Sir, your obedient servant,

Stockwell-road, S.W., May 28th, 1881. R. H. S. CARPENTER.

To the Editor of THE LANCET.

SIR,—During the last four years I have had occasion to apply to the National Vaccine Establishment for lymph about eight times, and I think it only just to that establishment to state that in every case the lymph has proved highly satisfactory, never having had a failure through it.

I am, Sir, yours, &c.,

May 28th, 1881. A GENERAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—I have been a public vaccinator for the last twenty years, and nearly always been furnished twice a year with a couple of tubes of lymph from the above institution to begin vaccinating with, during which period I can only recall to mind one or two failures, so think my testimony is of some value as to the quality of the lymph supplied to applicants.

I am, Sir, yours, &c.,

May, 1881. A PUBLIC VACCINATOR.

Mr. Richard B. Searle goes a little too far in claiming for those holding qualifications from Colleges of Physicians that they never forget what is due to the dignity of the profession. He errs, too, in a legal respect in saying that the possession of the degree of M.D. only conveys an honorary distinction. It empowers its possessor to recover charges for medical services just as well as does the Licence of a College of Physicians.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Lithgow, London; Mr. Partridge, London; Dr. Barrs, Leeds; Mr. Colston, New Whittington; Mr. W. H. Smith, London; Mr. W. B. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 1, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Clinical Lecture

ON THE

CATHETER-TREATMENT OF PERINEAL FISTULÆ.

BY J. C. OGILVIE WILL, M.D., F.R.S.E.,
SURGEON TO, AND LECTURER ON CLINICAL SURGERY AT, THE ABERDEEN ROYAL INFIRMARY.

GENTLEMEN,—I desire to direct your attention to the case of the patient now before you, who was admitted some time since on account of urinary troubles. When he was admitted to hospital he told ~~us~~ that some months previously he had fallen from ~~the~~ top of an omnibus, alighting on his buttocks ~~; that~~ a severe injury was inflicted on his perineum, that there was at the time a free discharge of blood from his urethra, that he micturated with great difficulty, that inflammation supervened, and that the surgeon under whose care he was opened an abscess which formed in his perineum, after which urine continually flowed from the wounds. Attempts to pass instruments into his bladder had been made, but they were unsuccessful. On examination, two large fistulous openings, one on the right and the other on the left side of the perineum, were found; and upon urethral exploration, an obstacle, which I had but little difficulty in recognising as a traumatic stricture, was found in the bulbous portion of the canal. When he micturated very little urine came by the meatus, most of it flowing from the fistulæ. The stricture was, as traumatic strictures often are, exceedingly difficult to penetrate, but with the aid of a very small elbowed French catheter I succeeded in reaching the bladder. The impression I formed was that, as a result of the injury inflicted on the urethra, there had been irregular adhesion of its lacerated edges, and that this and the subsequent cicatricial contraction had led to an alteration of the normal axis of the canal, so that it had assumed an angular form at its strictured part. This conclusion was arrived at from the impossibility of passing any straight instrument, stiff or flexible, or any metallic bougie with the ordinary curve; while an instrument with an angular or *coudée* end readily found its way into the opening of the stricture, and thence into the bladder; and I was strengthened in this belief by subsequent experience, for a like difficulty with the one instrument and a similar ease with the other was experienced until the stricture was dilated to a not inconsiderable extent. I may remark, by the way, that, had I confined myself to the use of the ordinary French flexible or English gum or metallic catheters, this case would in all probability have furnished an additional instance of impassable stricture, but the simple expedient of using an instrument suited to the exigencies of the case fortunately prevented any addition to that list in which no surgeon desires to figure.

Having now laid before you the condition in which our patient was found, let me next direct your attention to the means adopted for the dilatation of his stricture, and especially for the cure of the fistulæ.

Our first desire was—as it should be in every case where urethral fistulæ co-exist with stricture—to restore the canal to its normal calibre, and this we accomplished by a combination of the continuous and gradual dilatation methods, and you will often find that complete dilatation of the stricture is all that is required; for the urine, finding the barrier to its egress removed, flows through the natural channel, and ceases to pass into the fistulæ, which being relieved from the irritation arising from contact with such putrescent fluid, take on healthy action, and cicatrisation ensues. In this case, however, as often happens where there is loss of substance—i.e., where the openings are large, dilatation failed to effect a cure of the fistulæ, and I had now to consider how the access of urine to the fistulous openings might be most surely prevented.

Two methods of accomplishing this desideratum presented themselves—namely, (1) tying in a catheter; and (2) the systematic use of a catheter at each act of urination. As some of you know, I intended to adopt the former course, but the patient has himself so intelligently carried out the latter that a cure has resulted. If you will examine his perineum and scrotum—where a fistula had also formed —you will perceive that cicatrices mark the points where a few weeks ago there were masses of granulations, and the man tells us that "water now never comes the wrong way;" if he will maintain the position in which he is now placed, by the occasional passage of a bougie, his stricture troubles and their most distressing accompaniments are at an end.

The result is certainly most satisfactory, and has been obtained, I may tell you, much more easily than I could have ventured to hope. The treatment of fistulæ by tying in a catheter, of which I would now speak, has fallen into undeserved disuse, but in cases where you cannot rely upon the patient's intelligence in carrying out the method just mentioned, or where the urethra rebels against the frequent passage of a catheter, you will, I feel assured, find it most useful. I should, however, not conceal from you the fact that this mode has been "weighed in the balance and found wanting" by those who are justly entitled to speak with authority. Sir Henry Thompson has stated that on account of the capillary action which is set up between the sides of the instrument and the urethral walls urine flows out, and finds its way through the fistulæ. "This mode of treatment," he writes, "is to be regarded as inadequate to the cure of fistulæ, except so far as it produces dilatation; and it is one which has obtained countenance chiefly from the plausibility of a theory which is certainly unsupported in practice." Mr. Reginald Harrison, who has recently written on this subject, holds a similar opinion—viz., "I have never found any advantage from the retention of a catheter in the bladder with the object of curing a fistula, as the urine invariably makes its way into the fistula by the side of the instrument." To the adverse testimony of these two surgeons I could easily add similar opinions culled from the works of many other well-known and distinguished writers, but as I seek not to secure your condemnation of, but your favour for, this method, it would be unwise to so prejudice you as to prevent your acceptance of it.

For the purpose of proving that the opinions just quoted are not absolutely correct, and that the mode of treatment under notice is not deserving of the obloquy cast upon it, let me recall to your recollection two cases recently in this hospital. As the first one presents features of considerable interest apart from the result of treatment, I shall recite it at length. One evening I was sent for in haste to J. K——, who had been admitted after the hour of visit, suffering from retention of urine. The man was then suffering so acutely from the effects of retention that he was unable to supply me with the particulars of his case, but I subsequently learnt that he had been under treatment in hospital for stricture, and that he had been dismissed six weeks previously, a full-sized bougie having been passed. He had remained fairly well until a few days before his readmission, when he began to find difficulty in urination; thirty-six hours before he came under my notice he was attacked by complete retention, and he was seen by a medical man, who at that time and subsequently made attempts to pass a catheter but failed, and he was then sent here. On inspection a huge hypogastric swelling presented itself; there was great œdema of the scrotum and penis, and bulging of the perineum on the right side. On account of the perineal swelling no rectal examination could be carried out. Attempts to pass a catheter were unsuccessful, and the administration of chloroform, which was commenced, had to be stopped, as dangerous symptoms supervened. I at once determined to aspirate his bladder, and drew off two and a half quart bottlefuls of highly ammoniacal urine. The perineal abscess was freely opened and a considerable quantity of pus was discharged; it was odourless.

On visiting the patient next morning I found the house-surgeon in the act of applying the exhauster of the aspirator to the needle, which had been allowed to remain *in situ*, but no urine entered the receptacle. There was therefore no water in the bladder, a circumstance of which an explanation was speedily forthcoming, for the bed on which the man was lying was soaked with urine, which had found egress through the perineal opening. The œdema of the parts had become much lessened. Catheterism was still impossible, but two days later a bougie conduct rice was safely conducted into the bladder, and through a catheter, which was screwed on to the end of the conducting bougie and passed into the viscus, several ounces of urine flowed.

Before speaking of the treatment adopted for the cure of the fistula which thus resulted, let me give you in a few words my view of the pathology of this case. When I first saw the patient certain of the symptoms suggested rupture of the urethra and extravasation, for there was a history of prolonged retention, and an œdematous scrotum and penis. But the presence of an over-distended bladder disproved that idea, for I need hardly tell you that had rupture taken place the urine would speedily have found its way outwards, and would have spread into the perineum and scrotum, and upwards through the cellular tissue covering the abdomen. Further, the pus evacuated from the perineal abscess would have had a urinous smell, but it was odourless. The abscess was, in short, not the result of extravasation, but it was the cause of the retention, and the subsequent escape of urine through the perineal opening resulted from necrosis of the urethra occasioned by inflammatory action. If assistance had been but a little longer delayed urine would undoubtedly have been found mixed with the pus, and had relief been afforded at an earlier period rupture would have been averted. I have digressed from our subject, but the lesson which this case teaches is a vital one, and if it impresses you with the necessity for early interference in cases of perineal abscess the time devoted to its consideration has been usefully spent, for there will be no risk of your allowing a similar case to be followed by such undesirable consequences as ensued in this one.

Our patient's progress, though it was slow and protracted, can be laid before you in a very few words. When the urethra had resumed its normal dimensions, a full-sized English gum catheter was lodged, and the fistulous opening, which was a large one, gradually decreased in size, the discharge of pus and urine from it became less and less, and ultimately a cure was effected. Before that most desirable result was attained there were many vicissitudes, for during a period of several days we found that all the water came through the catheter, and then when it seemed that a cure was nigh, we were told that some drops of urine had found their way through the fistula. This latter circumstance was observed only when the catheter had lain in the urethra for some days, and its explanation was found in the fact that the eye of the catheter had become encrusted with the phosphates, and that the means employed were therefore imperfect. Acting upon this suggestive hint the dresser, Mr. John Reid, used a fresh instrument every three or four days, a procedure which perfectly overcame the difficulty, and from this time progress was uninterrupted. The oversight of the necessity of using a new catheter at short intervals furnishes us with one, at any rate possible, reason for the failure of this method of treatment in the hands of those who have employed it and condemned it; and if you should be called upon to adopt it, you should bear in mind our experience here. In tying in a catheter you will find the following plan a good one. Procure a flat, narrow india-rubber band, such as is sold by stationers, pass it over the glans into the groove behind the corona, and attach it to the catheter by two or more threads of well-waxed suture silk. This is a cleanly and efficient mode, and seems to me to be superior to plasters or tapes, which are generally recommended. The second case to which I have alluded as an example of the utility of bladder-drainage was one of long-standing multiple perineal and scrotal fistulæ, where many repeated and varied attempts at effecting their closure had proved futile. In this case extreme induration of the tissues was a most marked feature. Treatment by means of a catheter tied in was ultimately adopted, and in the course of a few weeks the abnormal openings were soundly healed, and the induration had completely disappeared.

These two cases show you that perineal fistulæ can be cured by this simple and easily carried out procedure; but a modification of this method, which I regard as a decided improvement, although I have not yet had an opportunity of putting it to the test of practice, has recently been proposed by Mr. Chiene of Edinburgh. His method of bladder-drainage consists in the establishment of a syphon, which he accomplishes by means of a piece of india-rubber tubing attached to a gum-elastic catheter, which is introduced so that its eye is just within the neck of the bladder, and it is kept in position by sticking-plaster. The tubing passes over the side of the bed into a bottle placed on the floor, and by filling the tube and the bottle with carbolic water a syphon action is set up. This is only a rough and imperfect sketch of the mode devised by Mr. Chiene; but you will find full details in his most suggestive paper contained in the *Edinburgh Medical Journal* for December, to which I refer you. Now, if the syphon action can be maintained we may regard the india-rubber tube as an elongation or prolongation of the ureters, for a direct and continuous connexion is established between the kidneys and the recipient vessel, and the bladder ceases for a time to exercise its normal function as a receptacle for the urinary secretion. Mr. Chiene has shown that this is possible; hence we must view this new mode as a decided advance on the old one, and with its introduction the objection to the catheter-treatment must disappear; and I believe that bladder-drainage will ere long become an established practice among those who are called upon to treat cases of urinary fistulæ.

ON HOSPITALS:

THEIR MANAGEMENT, CONSTRUCTION, AND ARRANGEMENTS IN RELATION TO THE SUCCESSFUL TREATMENT OF DISEASE, WITH REMARKS ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS.

By FREDERIC J. MOUAT, M.D., F.R.C.S.,

FORMERLY PROFESSOR OF MEDICINE, CLINICAL MEDICINE, AND MEDICAL JURISPRUDENCE IN THE MEDICAL COLLEGE OF CALCUTTA, AND FIRST PHYSICIAN OF THE HOSPITAL ATTACHED TO THE COLLEGE; DEPUTY INSPECTOR-GENERAL OF HOSPITALS (RETIRED); VICE-PRESIDENT AND FOREIGN SECRETARY TO THE STATISTICAL SOCIETY OF LONDON, ETC.

I.—THE CONTROL AND MANAGEMENT OF HOSPITALS.

BY no means the least important factor in the successful working of hospitals, is their right government. The concerns of all such institutions are many and various. For their proper regulation the fittest agency for each part of the appointed work should be selected, or elected. The general government, including the financial control, the special regulation, and the professional agency, superior and subordinate, are all necessary for their effective management.

In the general government, the public, as distinguished from the purely professional interests, should be chiefly regarded.

In the immediate management the professional element should not only be predominant, but absolute; for professional training alone can fit any man thoroughly to understand the multitude of matters of detail which require to be dealt with, with economy, despatch, and efficiency.

In most foreign countries the central and superior control is in the hands of a governmental administrative agency. In Paris, this is represented by the Director of the Assistance Publique, under the supervision of a council presided over by the Prefect of the Seine, and consisting of members of the municipal council, medical members, mayors, and other notabilities. The director is believed to be practically an independent officer in all executive measures. He has under his orders a staff, comprising a general secretary and several bureaux, each with its superintendent in charge, as may be found detailed in the French National Almanac.

The nearest approach to this organisation with us is the Local Government Board, which, however, in its attributes and functions differs very widely from it.

A cursory study of the laws of most European countries regulating the control and management of institutions devoted to the care of the sick, and to the relief of destitution, with which they are usually associated, has satisfied me that they will not fit easily into our system of self-government and absence of State interference; and that, beyond some useful general principles, there is little in them that will bear direct transplantation.

That our manner of dealing with them, although right in principle, is susceptible of considerable improvement in practice, I hope to be able to show when treating of the organisation of medical relief in this great metropolis, which is a kingdom in itself. The chief and most important change required, I hold to be the entire separation of sickness from mere destitution, this being merged in the general hospital system of the country, as an integral and inseparable part of the great question of public health; all other matters connected with destitution continuing, as at present, under the Poor-law authorities.

The hospitals themselves I consider ought to have just so much of State control as to secure their proper direction, with the remedy of such defects as may be shown to exist. I know of no good reason why the different hospitals of London and other great cities, should exhibit such very different risks to life in similar circumstances, diseases and accidents, as they do now, and have done for long past; and why a proper uniform system of hospital record in all departments of their administration should not be as compulsory as customs, trade, and other economic returns, in matters of far less general and scientific interest.

If the State interferes, as it does rightly, to protect all classes who are unable to protect themselves from injury and misgovernment, surely the sick and those who are afflicted by causes over which they themselves can exercise no control, demand the same consideration for the body, as they now receive for the mind and its disorders. It involves but the extension of a principle which is firmly established in our legislation, and it can easily be so regulated as in no way to interfere injuriously with the self-government which is still more deeply impressed on our national character, and guides us so surely and successfully in most matters of social and domestic economy.

In the lives of the poor, and of all engaged in manual labour, sickness plays a much more important part than it does in any other class of society. The munificent public and private charities of this country are amply adequate to deal with all legitimate demands upon them without inflicting additional burdens upon the purses, or taxes upon the time and attention, of the wealthy and benevolent, if they were only a little better organised, and somewhat more judicious care were bestowed upon their distribution.

GENERAL MANAGEMENT.

The general supervision of the concerns of all large hospitals should be in the hands of a mixed committee or body of governors, sufficient in number to be subdivided into sections of convenient size, to control the financial arrangements, additions to or alterations of buildings, and similar matters.

Should it not be deemed expedient to introduce an official element into this body, there is fortunately in such a community as ours, no lack of persons of cultivation and leisure strongly imbued with philanthropic sentiments, ready and willing to undertake such duties.

This general committee, by whatever name it is called, should be purely administrative, and have no executive functions.

On it should be men possessed of an adequate knowledge of finance, of structural arrangements, and of such economic principles as are required in the general control and direction of an establishment, whose special function is to do the largest amount of good to the sick and suffering, without prodigality or parsimony, and without fear or favour.

There are many circumstances connected with this general management of hospitals, in which the aid and advice of educated women would be valuable, both in council and in action. The laundry, the cooking department, the domestic arrangements of the nurses and female servants, as well as the women's and children's wards, would all benefit by such supervision. Hence, a certain proportion of all general committees should consist of ladies.

On the committee should also be the consulting physicians and surgeons of the hospital itself, and possibly other distinguished members of the profession, unconnected with the hospital, to act as a special medical committee; to see that, in the application of the means of relief, the institution is kept well abreast of the progress of the art and science of medicine and surgery, and to assist, in consultation with their lay brethren, to deal with abuses where they are found to exist, and, where technical and special knowledge are needed, to suggest the best means for their remedy or removal.

In such a body, the public and the profession would alike have confidence. The former would have the assurance that their money was well spent, that the hospital was humanely conducted, and that the poor and afflicted obtained all the advantages intended for them. The latter would be assured that the personal benefit of each patient was carefully considered, and that while none were made the subject of questionable experiments, the interests of the progress of science were not neglected, in introducing new and improved means for the cure, and, above all, for the prevention of disease—the latter being of national importance.

Such an organisation would not interfere injuriously, if at all, with vested interests or founders' wishes so long as these latter were in harmony with the constantly progressive changes in society, and the new conditions arising out of such changes.

The above is no hypothetical or speculative scheme, for, with some modifications of detail, it may be seen in active operation in some of the well-conducted hospitals of the United States at the present moment, and in the great hospitals of Edinburgh and Glasgow.

All persons engaged in inquiries into our hospital system know how difficult it is to obtain reliable information, and how little the public or the profession know of the exact state of most of our hospitals. This does not usually arise from any desire for concealment, but because each is more or less a law unto itself, and there is a want of uniformity in the system of records, which is seldom kept in such manner as to be of any real scientific or administrative value, so far as the published statements of hospitals indicate.

SPECIAL OR EXECUTIVE CONTROL.

The immediate government of a hospital should be entrusted to a resident Medical Superintendent. It is so generally in the United States of America, in some of the greatest hospitals of the continent of Europe, in the most important hospitals of Scotland, and in the large and well-managed separate Poor-law Infirmaries of this metropolis. To the medical superintendent all persons within the walls of the institution should be strictly and directly subordinate. There should be no concurrent, separate, or conflicting authority. He should not be charged with the treatment of the sick, and should neither possess nor exercise any power of interfering with the physicians or surgeons in their treatment of cases of disease, accident, or injury. The direction of all other internal concerns should be exclusively in his hands, such as the maintenance of order and discipline, the regulation of supplies of all kinds, the custody of all appliances and instruments, and the initiation of all such structural and other changes as may from time to time be found necessary. In matters of finance and supply he should act under the orders of the special sub-committees of finance and buildings, appointed from the general governing body. He should regulate the admission and discharge of patients, and the keeping of the records of the hospital, with the aid of such subordinate staff as is always required in great institutions. The out-patients' department should also be under his control. The appointment, removal, and distribution of all nurses, servants, and subordinates generally, should likewise be vested in him, subject to the immediate control of a house committee. He and all the sub-committees should submit an account of their proceedings, monthly, or as much or less oftener as may be deemed necessary, to the general committee at its appointed meetings, with whom should rest the final sanction and approval of all matters connected with the institution. The general committee should have a paid secretary to arrange and keep its records, and be the official medium of communication between that body and the officers of the hospital.

If there be any class or kind of public institution which more than any other demands the possession of special and technical knowledge, and more direct unity of authority in its immediate management, I hold it to be a hospital. A medical superintendent, from his professional training, is alone competent to gauge at once with promptitude and decision all the requirements of such an institution; and, as he must always be appealed to in the last resort, common sense and the proper conduct of business of all kinds in every other walk of life, indicate that he should possess the power, in the first instance, of dealing with every such matter as pertains to the economical and efficient control of a place devoted to the healing of the sick. Fettered as he would be by his responsibility to special committees and the general committee, there would be no fear of his abusing such authority, for a sure and swift remedy could be found for such abuse. But, as a matter of fact, it is not abused in those institutions in which it is in use, as I have had several opportunities of seeing.

However, even our existing system, mediæval and out of harmony as it is with the age in which we live, is better than that of the director of a French hospital, acting solely under the orders of a central official authority, which is about the most inefficient and mischievous form of government that I have ever seen in action.

Reform in the direction above indicated will not, I know, meet with ready acceptance from many benevolent and philanthropic persons, whose views are entitled to the most respectful consideration. We are as a people slow to mend our ways, and have a not unnatural dread of changes, which are usually regarded as more or less leaps in the dark.

Yet, this is in no way a speculative change, for it has long been in practical operation in other places, and is so in one important class of public hospitals among ourselves. Let those who have any misgivings on the subject visit and examine the institutions referred to for themselves, and see in their economy, efficiency, and the absence of all friction in their working, undeniable proof of the soundness of a system which has passed from the region of discussion to that of accepted fact.

The axiom that unity of executive control means efficiency of management, applies quite as much to public as to private business. Hospitals, I contend, form no exception to this, and the more general rule that those are best qualified to conduct a business successfully, who are best acquainted with its requirements.

NURSING.

The most important of all the subordinate agency required in hospitals, is undoubtedly that of nursing, of which indeed it would be difficult to over-estimate the value in its proper place, and in due restriction to its special purpose.

For the moral and domestic direction of the nurses, and for the thousand daily needs essential for their comfort and happiness, together with many collateral duties which a male superintendent cannot properly discharge, a matron is required—not as an independent and coördinate authority, but as an integral part of the machinery of management, kept in harmony by the single direct ruling authority.

That skilled and trained labour is infinitely more efficient and trustworthy than unskilled and untrained labour, is undeniable. But, to elevate nursing into a special profession, and to arm it with independent authority in the management of disease or accident, I hold to be a mischievous mistake, alike in public institutions as in private life. It is, and must always be from its very nature, a subsidiary function, but not the less valuable or important on that account. To elevate the minor to the position of the major, is as illogical in theory as it is unsound in practice.

Nurses stand in the same relation to the surgeons and physicians of a hospital that non-commissioned and warrant officers do to the officers of the army and navy, and that skilled artisans in a factory or workshop, do to the foremen and scientific directors of the works. To arm them with independence in any form, is as impolitic in the one, as it would be destructive in the other.

I cannot, again, concur in any scheme of connecting the duty of nursing with any form of religious or quasi-religious organisation; for hospitals are open to all classes, sects, and creeds, and should be absolutely free from even the suspicion of any sectarian bias, or proselytising tendency.

Far be it from me to underrate the possession on the part of a nurse of the deepest religious feeling, for there can be no better guarantee of her tender consideration for the sick, and of her conscientious fulfilment of her proper duties, which are entirely secular and professional, and should remain so. Nearly forty years ago I myself applied to the Roman Catholic Archbishop of Calcutta to grant me the services of some of his religious ladies, to organise and introduce into the female wards of the Medical College Hospital, then under my executive charge as secretary and resident medical officer, an improved and skilled system of nursing, at that time quite unknown in British India. He complied, and for some four or five years these exemplary and truly Christian women conducted the duties of nursing in the most perfect manner, under my constant personal supervision, and that of my late colleague, the then professor of midwifery. The successor of the archbishop above referred to, much to my regret and with many apologies on his part for taking a step in opposition to the action of his predecessor, withdrew the ladies in question. His plea was that the earnest devotion of the nuns to purely secular work, interfered with the strict performance of their religious duties. From first to last they never stepped beyond the exact line of their hospital work, so far as the sick were concerned, or assumed functions or powers inconsistent with their relations to the professor or myself. The harmony of action and efficiency of nursing were unbroken, and we parted with mutual regret and regard. I assume, then, to speak with authority on a question which has recently greatly exercised the public mind, and which, in the instance referred to, is now happily at rest.

I do not enter into the question of the right method of training nurses, because it would need a paper to itself, and is not necessary to my contention. Moreover, it has been treated exhaustively by one who can never be mentioned without an expression of the respect and admiration due to exceptional knowledge of the subject, to rare ability in its consideration, and to a life-long devotion to a work which will for all time be associated with her name.

The nursing department of St. Thomas's Hospital, the excellent arrangements of the great Infirmaries in Scotland, and the special provision for the same end made at the Johns Hopkins Hospital at Baltimore, with many others which might be mentioned, are all typical and efficient modes of dealing with the question of training, in the only manner that appears to me to be thorough, and free from objection.

The mode of appointment of the medical officers of all civil hospitals in the kingdom is probably not free from objection; but so long as it brings the best men to the front, and secures to the sick the ability and care necessary for their restoration to health, there is no pressing reason for suggesting a change. To men possessed of the requisite knowledge and skill, hospital offices are sure passports to public favour and to professional reputation. This will, however, do little for those who lack the higher qualities which go to the formation of a perfect surgeon and physician, such as are to be found in all our great institutions.

(To be continued.)

THE PATHOLOGY AND TREATMENT OF DIARRHŒA IN PHTHISIS.

By C. THEODORE WILLIAMS, M.A., M.D., &c.,

PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

Diarrhœa is often the cause of fatal termination in phthisis, its exhausting discharges reducing the weight and impoverishing the blood more than the cough and expectoration, or even than the fever. Three different kinds of diarrhœa are met with during the course of the disease. 1st, That arising from acidity of the primæ viæ; 2nd, from intestinal ulceration; 3rd, from lardaceous disease of the intestines. A great deal of the diarrhœa connected with the first stage of phthisis is attributable to the first cause, and many practitioners think when they have allayed this, they have arrested ulceration, whereas they have only got rid of dyspepsia. It is unnecessary to dwell on this form, which as a rule arises from over-feeding patients, and is accompanied by a coated tongue, tenderness in the right hypochondrium and epigastrium, loaded urine, anorexia, flatulence, and frequent light-coloured stools.

The second form, or intestinal ulceration, is the commonest cause of fatal diarrhœa in phthisis, and prevails in a considerable proportion of third-stage patients. Louis found ulceration of the intestines in five-sixths of his cases, Bayle in 67 per cent. of his, Lebert in 67 per cent. of his Breslau ones, and in only 39 per cent. of his Zurich ones. The Brompton Hospital post-mortem book for the last twelve months gives the following. Out of seventy-five cases of phthisis in which the intestines were examined, sixty-one had ulceration of a tubercular nature, giving a percentage of 81, a higher percentage than that of either of the above authorities except that of Louis. It is only right to state that a most careful search was made on each occasion by the present pathologist, Dr. Ewart.

The pathology of tubercular ulceration requires a large number of specimens to display its exact course, most autopsies only showing the last destructive stages.

Ulcers are to be found occasionally in nearly the whole intestinal tract below the duodenum, but they are so extensive and involve so great an amount of the mucous membrane of the large intestine as often to give it an entirely wormeaten appearance, and in many instances the large intestine of a case of phthisical diarrhœa cannot be distinguished from that of tropical dysentery, so well portrayed lately by Sir Joseph Fayrer in his Lettsomian Lectures. In the small intestine, however, especially in the ileum, we are able to trace the early steps of the ulcerative process, and I hope the cases I am about to relate will illustrate these. The first stage consists of an inflammatory hyperplasia of the solitary and agminate glands, as shown by their prominence when the intestine is opened. The second stage consists either in their conversion into pustules by formation of matter, or by their undergoing caseation. Either phase is followed by the third stage, which is the evacuation of their contents, leaving behind ulcers with smooth floors and sharp, clear-cut edges. Up to this point the process is held by many authorities to be inflammatory, and not strictly tubercular. After a while grey tubercle is detected in the floor of the ulcer, which in time undergoes caseation, causing extension, vertical or lateral, of the original ulcer.

The secondary tubercles follow the line of the bloodvessels, and sometimes are seen from the peritoneal surface, demonstrating how deep these ulcers extend. When ulceration has arrived at this stage, each spot presents thickened irregular edges and an uneven floor. The intestinal wall around them is generally thin and wasted, and it is often easy to recognise the ulcerations from outside without opening the intestine. In time, these patches, extending, join neighbouring ones, and eventually the whole circumference of the mucous membrane becomes a mass of disease. It is in this condition that we often find the colon and sigmoid flexure. Before ulceration, however, reaches this degree, it is not uncommon to find separate ulcers of great length; Louis found one measuring eight inches, the floor being formed by the muscular coat, except in the centre, where even this had disappeared, and only the peritoneal coat remained. Considerable thickening of the peritoneal coats, especially in the region of the ulcers, takes place, and thus it is that perforation is comparatively rare. When it occurs, peritonitis is inevitably set up, but even then it is sometimes of a localised description, the extravasations being walled off by fresh adhesions. As a rule, however, the peritonitis is general, and death soon follows the perforation. Rindfleisch gives a case where several coils of the intestines were adherent, and perforations took place in the adjacent portions in five different places. Occasionally vessels are penetrated by the ulcerative process, and death occurs by hæmorrhage. Hanot states that he saw two such instances in the service of M. Lasègue, in each case the amount of blood lost being very striking. After death the source was found to be a small opening in a vessel in the middle of a Peyer's patch, which was deeply ulcerated. Biermer gives a case of large intestinal hæmorrhage following tuberculous ulcer of the rectum in a child.

These are the most unfavourable pathological courses of the process; but, on the other hand, the ulcer may shrink, the walls become more indurated, and at length form a puckered cicatrix in the mucous membrane, largely contracting the circumference of the intestine; and in patients dying of chronic phthisis these scars are occasionally seen.

Accompanying the ulcerative changes we often find considerable swelling of the mesenteric glands, but this is generally the case in the later stages of the disease. Walshe found alteration in these glands in from one-third to one-fifth of his cases of phthisis.

Let us now take some examples of intestinal ulceration to illustrate the above remarks.

CASE 1 is one of advanced phthisis, with the common accompaniment of disease (chiefly lardaceous) of the liver and kidney, giving rise to ascites and anasarca, but at the same time intestinal ulceration was proceeding, causing obstinate diarrhœa. John B——, aged twenty-nine, draper's assistant, was admitted into the Brompton Hospital, Oct. 30th, 1879, with a history of cough, loss of voice, expectoration, and wasting for eight months. Night sweats commenced with illness, but have ceased lately. Diarrhœa appeared a month ago, but stopped in fourteen days; then œdema of the legs and ankles commenced. On admission the appetite was good; cough and expectoration moderate; temperature, pulse, and respiration all normal; weight 8 st. 5¾ lb.; pupils rather contracted; urine contained albumen (¼). Examination of the chest showed dulness, flattening over the whole left chest; cavernous tinkle was audible from the clavicle to the third rib, and above the scapula, and crepitation was heard below these points. Hepatic dulness was increased upwards. In December the patient became excited and wandering in manner and speech. The bowels were costive, the albumen increased to ¾ of the test-tube; the œdema became more extensive. After free purging the head symptoms subsided; the œdema diminished, and the amount of albumen was reduced to ⅜. Diarrhœa returned on the 28th of January, 1880, and at first was very moderate, the motions being two or three daily. It gradually increased to five motions a day at the end of February, but under a simple regimen of milk and beef-tea the daily number of stools was reduced to three. On the 11th of March the patient became so weak that a more generous diet, including brandy, was adopted, and the diarrhœa increased to nine and eleven motions a day. Under opiate and astringent enemata it was reduced to two motions a day, but the number speedily increased if the enemata were omitted. On the 2nd of April the œdema increased, and ascites made its appearance; the urine continued abundant, with a large percentage of albumen. Cavernous sounds became audible in the right lung, the breathing became more and more difficult, and on the 29th of April he died, the diarrhœa continuing till the end.

Autopsy, twenty-seven hours after death, by Dr. EWART.—Abdomen: The peritoneum contained a pint and a half of pale opalescent fluid. The mucous membrane of the stomach was thickened and pasty and covered with glairy mucus. The upper portion of the intestine was normal; but from the lower third of the ileum downwards the gut was much ulcerated. No distinct tubercle was recognisable in connexion with the ulcerations. These were clearly of follicular origin, and they appeared to result more immediately from the rupture of purulent accumulations (similar to those commonly seen in follicular tonsillitis), some of which were as large as a split pea, or rather larger. The next step of the ulceration was characterised by a clean floor and a very sharp edge. Lastly, in some places, a third step was recognised—viz., that of shrinking and of induration. This was especially noticeable where several ulcers and pustules were arranged in a row in the transverse diameter of the ileum. The ascending and transverse colon were wormeaten by serpiginous and circular ulcers, situated so close to each other as to scarcely leave any healthy surface. Scattered ulcers were found as far as the rectum. The mesenteric glands were not much enlarged; one was calcified. The liver weighed 3 lb. 4 oz.; it showed fatty and fibroid changes to the naked eye, but isolated streaks and dots of deep brown appeared when iodine was applied. The spleen weighed 15 oz.; it showed a few infarcts and some lardaceous changes. Pancreas: Bloodvessels distinctly lardaceous. The kidneys weighed 19 oz.; smooth, pale, with pink pyramids; the cortex showed opaque, yellowish-white streaks, within a semi-transparent basis. Iodine turned several of the Malpighian capsules brown. The kidney was a good specimen of the large white variety, combined with lardaceous disease. Heart: The mitral anterior flap had a small fibrinous vegetation on it. Lungs: Both pleuræ adherent; left anterior lobe occupied by a large vomica with fibrous wall; posterior lobe shrunk, contained tubercular mass in process of softening. The right upper lobe contained a large cavity full of grumous fluid, the rest of the lung being spongy and pervaded by tubercular nodules undergoing rapid softening. The mucous membrane of bronchi thickened. Bronchial glands: The subtracheal one was large, firm, red, and had a patch of pigmentation, but no tubercle. The larynx showed pinhole ulcerations and eroding of the vocal cords.

CASE 2.—William W——, aged sixteen, single, was admitted into the Brompton Hospital on May 11th, 1880, with a history of cough and expectoration for eighteen months, the latter occasionally streaked with blood. Diarrhœa had persisted for two months, and night sweats for a longer period. Great emaciation had resulted. On admission the cough and expectoration were moderate, the breath short on exertion, and the tongue red and irritable; the bowels relaxed twice daily. Pulse 104; temperature 99° F.; urine, sp. gr. 1015, acid, contains no albumen; weight 6 st. 8 lb. Physical signs: Dulness and cavernous sounds audible from the clavicle to the third rib on the right side; some dulness above the scapula. On May 19th the patient was seized with symptoms of acute nephritis; albumen appeared in the urine, and crepitation was audible at the bases of both lungs, in addition to the above physical signs. The acute symptoms passed off in ten days, the diarrhœa being somewhat less during their persistence; but albumen continued in the urine up to the patient's death. The diarrhœa returned at the end of June, and gradually increased, in spite of all treatment, from three stools to ten stools daily, the medicines used being bismuth, bismuth and opium, sulphate of copper and opium, turpentine, enema of opium with acetate of lead, &c., with tannic acid, and also injections of linseed-tea and opium. With the exception of the last-named, which reduced the number of motions for a time to two daily, none of the above can be said to have in any way controlled the diarrhœa. Great pain in the umbilicus was noted at the beginning of August. The albumen towards the end of the patient's life amounted to seven-eighths of the tube, and at one time the urine after boiling was solid, and both œdema and ascites were present. The patient sank on August 30th.

Autopsy, twenty-four hours after death.—Abdomen contained a small amount of fluid. Intestines showed ulcerations in the jejunum and ileum, and in the large intestine. They were of two kinds—(1) small and round, resulting from simple softening and destruction of tissue; lower down in the intestine were (2) larger ones, possessing a rather thickened floor, in which miliary tubercles were present and visible on the peritoneal surface of the bowel. The neighbourhood of the ileo-cæcal valve was severely ulcerated, and the colon formed one continuous ulcer. From the ileum downwards both forms of ulcer occurred side by side. The liver was fatty and lardaceous, the spleen very lardaceous, the kidneys smooth and pale, with pink pyramids. The changes of chronic tubal nephritis were well marked. Malpighian capsules lardaceous, giving a strong iodine reaction. Heart normal, except tricuspid orifice somewhat dilated. Lungs: Right pleura adherent; right lung contained a large smooth-walled cavity, the size of an orange, and a smaller one lined with a glistening membrane. The lower lobe contained abundance of grey tubercle, either isolated or grouped; many of these last were in the process of softening. Left lung inflated, with some cicatrices at the apex. Bronchial glands enlarged, and contained miliary tubercles. Larynx and trachea: Extensive ulcerations occupied the whole tract from the tip of the epiglottis to the second division of the bronchi. The mucous membrane of the larynx was much thickened, and there was considerable hyperæmia of the trachea and bronchi. Ulcers were present in the pharynx, on the buccal surface of the epiglottis, on the base of the tongue, and the tonsils were hollowed out by caseation.

Remarks.—Both these cases are cited to illustrate the morbid anatomy of ulceration. Case 1 shows well the first steps in the process—the swelling of the glands, their suppuration, and caseation; Case 2 the different forms of ulcer, and the secondary infection which takes place in and around them. As in both instances renal disease existed to a considerable extent, and exercised a large influence on the symptoms, these cases cannot be considered good clinical examples of intestinal ulceration, but they are undoubtedly good ones of the morbid anatomy. It is seldom that so much destruction of the mucous membrane exists as occurred in Case 2, for here the pharynx, larynx, and bronchi, in addition to the intestines, were attacked. No history of syphilis could be traced in either.

CASE 3 is a good instance of perforation and peritonitis. Charles C——, aged nineteen, admitted October 7th, 1881, into Campbell ward, with the following history. He was attacked one year ago with pain in the left side, chiefly on taking breath, accompanied by diarrhœa and followed by pains in abdomen. Pains subsided, but were followed by cough, expectoration, night sweats, and wasting. When admitted his cough was moderate; expectoration scanty; appetite very bad; tongue red and irritable. Pain was complained of in the lower part of the abdomen. Bowels open three times a day. Pulse 80; temperature 103° F.; respiration 20. The physical signs showed the existence of a cavity at either apex. Bismuth and opium were given internally, and linseed poultices applied to the abdomen; but as the pain in the abdomen persisted, a blister two inches square was applied over the seat of pain. The diarrhœa ceased, and the cough became less frequent, but the pain persisted. On the 19th the pain had extended over the whole abdomen, and there was tenderness on pressure, chiefly over the right side. Tongue furred; bowels relaxed; hands and feet cold. Two days after he died suddenly.

Autopsy.—The abdomen contained abundant purulent fluid, encapsulated in the lower parts of the abdomen by fibrous adhesions. In the process of unravelling the gut, three perforations were detected in connexion with the encapsulated portions of the peritoneum. The intestines presented large ulcers from the middle of the jejunum to the end of the rectum, being most numerous and best marked in the ileum. No tubercle was visible in the peritoneal coat. The ulcers were devoid of raised edges and free from thickening, except where a few granulations were commencing; the ulcers appeared to enlarge by gradual implication of the neighbouring solitary glands. The mesenteric glands were swollen, some were suppurating and others caseous. The lungs showed both pleuræ strongly adherent at the apices. Both lower lobes were spongy and but slightly congested, but contained fresh translucent tubercles scattered through them. The upper lobes showed congestion of deep venous colour, interspersed with numerous nut-sized cavities containing yellow matter. The cavities, which had apparently been recently formed in the partially indurated tissue, were lined and stood in direct connexion with several funnel-shaped bronchi, and were situated at the periphery of the lungs. Various caseous masses, of apparently broncho-pneumonic origin, were noted in the upper lobes. No tubercle was detected in the upper lobes. The tissue intervening between the cavities under the action of spirit was deprived of its congestion and showed pigmentation and old fibrous changes. The bronchial glands were pigmented; the other organs were healthy.

Remarks.—This is a fair instance of extensive ulceration leading to peritonitis, partial probably at first, as shown by the encapsulated portions, but afterwards more general. The state of the lungs indicates that an attack of pleuro-pneumonia, probably of both lungs, led to induration of the tissue of the upper lobes, and consequent dilatation of the bronchi. These bronchectases extending and forming collections of muco-pus in the neighbourhood, the lymphatics became implicated, and hence the fresh tuberculosis. The difficult point to determine is when the intestines became implicated, and whether their lesions occurred first, and were the starting-point of the systemic infection, or whether the bronchectases were so. The history was not sufficiently distinct to decide this.

(*To be concluded.*)

ETIOLOGY AND CLINICAL BEARINGS OF THE GERM THEORY OF DISEASE.

BY DR. GEORGE HARLEY, F.R.S.

The Editor calls attention to the following

Note by the Author.—"Reformed speling: This paper is printed without encumbering its words with redundant, and consequently useles, duplicated consonants."

It must be understood that THE LANCET does not adopt the method, but simply complies with the request of Dr. Harley.

CHAPTER II.

Efects of Animal Germs and Germ-spawn artificialy introduced into the Bodies of Healthy Animals.

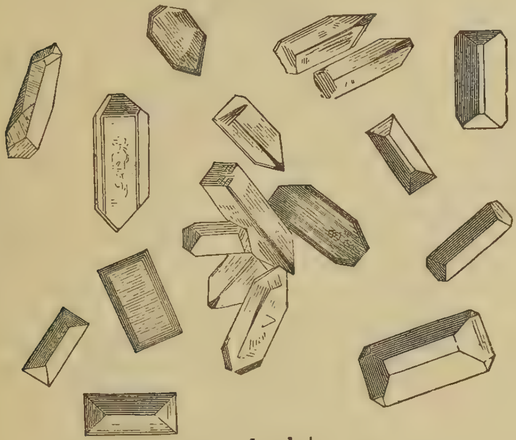
THE first experiment made with what I consider animal germs was the folowing:—

(F) A quantity of normal healthy gastric juice was withdrawn from a healthy dog's stomach through a fistulous opening. It was set aside in a smal-neck botle until it had not only become putrid, but strongly alkaline, and ful of living animal organisms;[1] though, strange to say, not a single spore nor filament of a fungus was to be detected in it by the aid of the microscope. An ounce of it, without any preparation whatever, was then slowly injected into the left femoral vein of a large dog. On the folowing day it apeared out of sorts, and refused its food. It rapidly recovered, however, and in four days was aparently perfectly wel. This result surprised me, seeing the deleterious results I had seen folow the injection of putrid blood, and even of blood directly withdrawn from the vesels of starved living animals, and it led me to try to ascertain if the deleterious efects of putrid animal maters were proportionate in any way to what by our senses we would consider to be relative degrees of abomination. With this object in view the most disgusting looking and smeling animal liquid was sought for, and it was suposed to be discovered in the macerating trough of the disecting-room, which had not been emptied for years. On placing a drop of the filthy-smeling alkaline fluid from the macerating trough under the microscope it was found to literaly swarm with actively-moving Brownian granules, vibriones, and germ-spawn. It also contained numbers of crystals of triple phosphates. An ounce of this was injected very slowly into the femoral vein of a dog. It seemingly caused it not the slightest imediate inconvenience, as it at once troted of to its food, and began eating it as if nothing had been done to it. Within twenty hours afterwards, however, it was found dead. The deadly efects of this ofensive animal fluid being therefore undoubted, I resolved to try if the germ-spawn contained in the liquid would alone be suficient to kil an animal. Litle thinking that the result I would obtain would give a solution to the aparently mysterious fact, long afterwards noticed by other observers, that splenic fever (which is due to the presence of bacili in the circulation) could be induced in healthy animals by inoculating them with blood of infected animals when no bacili were visible in it, and yet in the course of time bacili would develop and be found in the blood of the animals so inoculated. This I explain by saying that, although there were no bacili in the blood inoculated, it nevertheles contained bacili germ-spawn.

---

[1] Gastric juice contains a special ferment of its own caled pepsin, which, when introduced into milk, induces lactic acid fermentation; whereas, when acting in its own normal secretion—gastric juice—it sets up an alkaline-amoniacal fermentation, similar in its results, though not in its mode of action, to the alkaline-amoniacal fermentation of normal acid urine.

FIG. 6.



Triple hosphates.

(G) To test the value of my germ-spawn theory I proceeded as folows :—

A quantity of the putrid liquid from the macerating trough was carefuly filtered through filtering-paper which only alowed the minute—almost invisible—germ-spawn and the soluble materials in the liquid to pas through it. The vibriones and Brownian granules, together with al the solid substances it contained, were retained behind on the filter.[2] An ounce of the thus prepared foul-smeling water, suposed to be loaded with germ-spawn, was slowly injected into the left jugular vein of a ful-grown terier dog. The imediate efects of the operation were simply *nil;* but they would not have remained so long, for next evening—that is to say, within eighteen hours after the injection had been made, the colege servant on going to seek the dog found it very il; so il that he at once took it up in his arms and brought it into the laboratory. On my arival there at 10 A.M. I found the animal in an almost comatose state. Its respiration was only 7 per minute. Its femoral artery was nearly pulseles. Its skin was cold, and it not only could not stand on its legs, but it had scarcely power to move them. A smal quantity of blood was withdrawn and examined under the microscope, but nothing abnormal was found in it. Some of it was put aside to crystalise, on acount of my having noticed that rat's blood under similar conditions crystalised unusualy readily; but no crystals whatever formed in it. On the folowing morning the animal was found not only dead, but stif. Strange to say, notwithstanding this, its body smelt most ofensively, and yet the rigor mortis proved that the foul odor was not due to the result of ordinary tisue decomposition.

Extravasations of blood had taken place under the skin and into the muscles, especialy about the animal's neck in the neighborhood of the wounds. The duodenum was found filed with sanguinolent mucus, and its mucous membrane was uniformly red and congested-looking, with one or two points of extravasation. This is a point to be noted from its having a particular bearing on the cause of the black vomit and tary dejections met with in cases of hepatic disease—where there is a complete suspension of the biliary secretion—and hæmorhages take place into the digestive canal. It has an equaly important bearing on the pathology of putrid fevers.

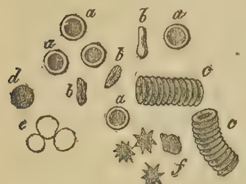
(H) Being satisfied by the results of these and other experiments, of a precisely similar character, of the deadly efects not only of animal micro-organisms, but of their germ-spawn when directly introduced into the circulation of a healthy animal, I determined to ascertain if this same chain of pathological results could be induced by the local aplication of the same abnormal living elements to healthy living tisues. In order to insure that the inoculation, if it took place at al, should be the result of thorough contact, I injected half an ounce of the same liquid as was used in the preceding experiment, under the skin of the back of a perfectly healthy dog. No imediate results folowed upon the operation. On the folowing day it apeared perfectly wel, with the exception of a slight pufines being observed under the skin at the seat of the injection. But even that apeared to give it but litle inconvenience, as it alowed the part to be gently manipulated without manifesting any symptoms of pain. In three days even this had disapeared, and the dog seemed perfectly wel. The slight results here obtained (as I knew from the previous experiments that the liquid was not inocuous) could only arise from one of two things—either that the quantity employed was too smal, or that the dog was unusualy insusceptible to its efects. With the view of ascertaining which of these ideas was most probably the corect one, I proceeded to increase, not only the actual quantity of germ-spawn, but also the area of the healthy tisues with which it was brought into contact, by injecting an ounce—that is to say, double the quantity of fluid—under the skin of the back of another aparently equaly healthy dog of the same species, and almost of the same size. As in the former case, the operation at first seemed to be perfectly harmles. For not the slightest inconvenience did it apear to cause the dog; a very diferent thing from what would have ocured had a dead alkaloid, or a dead mineral poison, been introduced in suficient quantity to produce deleterious results, as this was, as the sequel will show. Nevertheles the germs were actively at work. They had found a suitable habitat, and they evidently lost no time in seting about the fulfilment of their mision, which was to hatch, grow, and multiply at the expense of the healthy tisues of their involuntary host. The disintegration of its tisues caused iritation. The iritation induced morbid action, and what was its result? Nothing more nor les than that within the brief space of twenty-four hours a soft pufy sweling ocupied the seat of the injection. Within forty-eight it asumed the form of a circumscribed œdematous tumor.[3] On the fourth day an ulcer of the size of a sixpence had formed at the seat of puncture, while al around it, over a space of about the diameter of a florin, the skin had become perfectly denuded of its hair, which strongly reminded me of what hapens in the disease known as moluscum contagiosum, in which tumors form and the hair fals of, not improbably from a similar kind of cause—namely, disease germs finding their way into the hair-folicles. The dog's general health apearing to be unafected, and wishing to make a careful inspection of the parts round the seat of the injection, I kiled it by pithing, and the folowing is the result of the post-mortem examination. The ulcer at the seat of puncture was found to comunicate directly with a large (three inches in diameter) subcutaneous cavity, caused aparently by the fluid having detached the celular tisue from the fascia beneath. But the wals of the cavity were free both from any apearance of putridity and any great inflamatory action. At least no pus was visible, and only a red layer of serous exudation found, in which was seen, by the aid of the microscope, inumerable granular nucleated large exudation corpuscles, the nuclei being rendered very distinct by the adition of acetic acid (see Fig. 5). Beyond that, and that the blood cels showed in this case a marked tendency to serated edges, nothing remarkable was noticed. Having obtained a result which to my mind clearly proved that quantity as wel as quality was a factor not to be omited in calculating the value of the pathological efects of germs in these experiments, I resolved to operate on smaler animals, and with this view tame Japanese rats were employed in the next experiments.

---

[2] Although ordinary white chemical filtering-paper retains the germs and only alows the minute germ-spawn to pas through, it is easy enough to devise a form of filter, as Pasteur did, which alows neither germs nor germ-spawn to pas through, so that if it is desired to operate on fluids devoid of al taint of germ-spawn a coton-wool or other kind of filter from that of mere filter-paper must be had recourse to.

[3] Lukomsky got similar results—namely, phlegmonous subcutaneous inflamations—by injecting under the skin of rabits erysipelatous fluids. (See Koch, 1880, p. 10.)

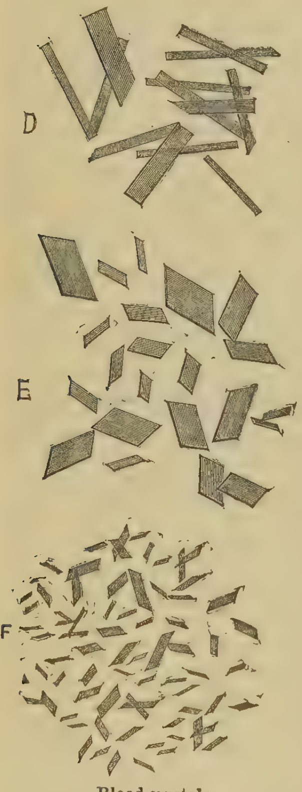
FIG. 7.



Serated blood cels.

(J) Under the skin of the back of a tame black and white rat was injected a fluid drachm of the afore-mentioned fetid water from the disecting-room macerating trough, swarming with animal germ-spawn. Next morning—that is to say within twelve hours,—the rat was found dead and stif with rigor mortis. Round the seat of puncture the skin was not only congested, but somewhat œdematous. The blood was coagulated, and, what was more to the point, when examined under the microscope it was found to be ful of wel-formed crystals, some almost colorles, some pink. Rat's blood is particularly prone to crystalise, especialy under many diferent pathological conditions. But this rat's blood was exceptionaly so, for it may be said to have become literaly cramful of them the moment a drop of water was aded to it. In fact, the whole field of the microscope became covered with large prismatic flat band and needle-shaped crystals, which imediately disolved on the adition of weak hydrochloric acid. When a litle acetic acid, solution of potash, or alcohol was aded before the adition of the water no crystals whatever were found. This strongly reminds me of the fact recorded by Charcot and Robin in the Comptes Rendus of the Société de Biologie, 1853, that the long prismatic crystals met with in the blood in the cases of leucocythæmia, though insoluble in water, are nevertheles soluble in acid and alkalies. The solubility of these crystals both in alkalies and acids met with in rat's and human blood, coupled with their insolubility in water, lead me to suspect that they are of a cholesterin nature, and simply tinted with the coloring mater of the blood. Besides these prismatic flat band and needle-shaped crystals there were also in this rat's blood a few much reder, colored stelate ones, such as I had never before seen in rat's or in any other animal's blood, notwithstanding my familiarity with al kinds of blood crystals (see page 49 of the second edition of my "Histological Demonstrations"). The stelate form put me more in mind of the rare star-shaped uric acid crystals of human urine than anything else. The result of this experiment was so unusual that I imediately repeated it on another brother rat, and that, too, with perfectly identical results in every single particular. I have only to ad that in my notes no mention is made of anything else abnormal having been observed in the blood of either rat.

FIG. 8.



Blood crystals.

In researches published in 1880, we are told that Koch found that the injection of putrid fluids into rabits led on one ocasion to the formation of a spreading absces. The wals of this absces were found to be ful of micrococi; and these micrococi, inoculated on another animal, again produced the same spreading supuration. The blood of these animals produced the disease in mice, and at the same time he got in some cases a peculiar progresive destruction of the tisues in the mice, and he found this was due to the spread of an organism—streptococus—in the tisues. At first he was unable to separate this organism from the bacilus, although he easily separated the bacilus from it, for the minutest portion of the fluids contained not only streptococi, but also bacili. He separated them by injecting material containing both forms into a field mouse. This animal is insensible to the bacilus, but not to the streptococus, which grows in it readily.

Koch also found that the fluid obtained by macerating mouse's skin in water for two days produced pyæmia in rabits. The cause of this pyæmia being a minute micrococus growing in the blood-vesels, and causing the red corpuscles to adhere together. In this way, emboli, consisting of mases of these organisms, with entangled blood-corpuscles, were formed; and Koch sugests that in man a similar proces may explain the obscure formation of emboli in the smal arteries. He also got a septicæmia in rabits, and found it to be dependent on a smal oval organism growing in the blood; while, lastly, erysipelas was on one ocasion found to be produced, and in this case long and large bacili were seen over the erysipelatous part.

Having now, I think, by the results obtained from the experiments of others as wel as my own, conclusively shown that there are both benign and virulent forms of microscopic organisms, and that the aparently benign may be made to produce virulent pathological efects, not only by altering the soil in which they grow and the materials upon which they feed, but also, as I shal presently show, by merely transfering them into parts of the body where they are abnormal, and find a suitable habitat in their abnormal situation for development, reproduction, and multiplication, —I shal proceed in the next chapter to clasify what, acording to the present state of our knowledge, I think, may be regarded as the distinct forms of germs which are capable of producing specific pathological results in the human body. I am constrained to do so, as it apears to me, as it must have done to many others, that some sort of clasification of disease-germs has become absolutely esential, from the fact that many writers include under the general terms of bacteria and micrococi several distinctly diferent morphological germs—to wit, the spheroidal micrococi, the sausage-shaped bacteria, and the rod-like bacili. So that in reading their papers it is imposible to know which form of germs they are realy speaking of. No doubt we are not as yet in a position to say—for reasons which I shal subsequently give—which are and which are not distinct species of germs; but, as we shal see in the next chapter, we already know that such distinctly diferent morphological germs as micrococi, bacteria, and bacili give rise to distinctly diferent and definite pathological results, both in the human subject and in animals into which they are artificialy inoculated. I even live in the hope that there may yet be discovered a distinct microscopic organism for each distinct contagious and infectious disease, which appears to me to be rendered al the more probable by the already discovered fact that diferent species of animals have diferent degrees of susceptibility to diferent forms of germs. Even a field mouse resists the atack of a bacilus to which a house mouse sucumbs. I therefore think that the time has arived when it has become imperatively necesary for us to make at least some tentative form of arbitrary clasification of the disease germs with which we are already acquainted, so I propose to give a table and figures of them in my next chapter.

(To be continued.)

THE surgeons of the Poplar Hospital have given testimony to the value of the services of the St. John Ambulance Association. "We have noticed," say Messrs. Brownfield, Corner, and Bowkett, "that since the formation of classes at the Docks for aid to the injured, the persons brought to the hospital suffering from accidents have been saved much pain before being admitted, owing to the preliminary treatment they have received at the hands of members of the Association."

NOTES ON THE

SYSTEMATIC TREATMENT OF NERVE PROSTRATION AND HYSTERIA CONNECTED WITH UTERINE DISEASE.

BY W. S. PLAYFAIR, M.D., F.R.C.P.,
PROFESSOR OF OBSTETRIC MEDICINE IN KING'S COLLEGE AND PHYSICIAN FOR THE DISEASES OF WOMEN AND CHILDREN TO KING'S COLLEGE HOSPITAL.

(Concluded from page 859.)

CASE 2. — In May, 1880, I saw with Dr. Julius of Hastings an unmarried lady, aged thirty-one. Her history was that she had been in fairly good health until five years ago, when, during her mother's illness, she overtaxed her strength in nursing, since which time she had been a constant invalid, suffering from backache, bearing-down, inability to walk, disordered menstruation, and the usual train of uterine symptoms. She used to get a little better on going to the seaside, but soon became ill again, and in October, 1879, she was completely laid up. The least standing or walking brought on severe pain in her back and side, and she gave up the attempt, and had since remained entirely confined to her bed or sofa, suffering from constant nausea, complete loss of appetite, and depending on chloral and morphia for relief. Many efforts had been made to break her of this habit, but in vain. Her medical attendant had recognised the existence of a retroflexion, but no pessary remained *in situ* for more than a day or so, and he suspected that she herself pulled them out. I was unable to do more than confirm the diagnosis that had been made as to her local condition, but the pessary I introduced shared the fate of its predecessors, and she remained in the same condition—in no way benefited by my visit. Things going on from bad to worse, Dr. Julius sent her to London for treatment in the early part of December. I now determined to try the effect of the method I am discussing, of which I knew nothing when I first saw her. It was commenced on Dec. 11th, and everything went on most favourably. A week after it was begun, when her attention was fully occupied with the diet, massage, &c., I introduced a stem pessary, being tempted to try this instrument, which I rarely use, by the knowledge that she was at perfect rest, and that no form of Hodge had previously been retained. I do not think she ever knew she had it, and it remained *in situ* for a month, when I removed it and inserted a Hodge, which was thenceforth kept in without any trouble. I may say that I do not think the retroflexion had much to do with her symptoms, except, doubtless, at the commencement of her illness, and she probably would have done quite as well without any local treatment. She rapidly gained flesh and strength, and very soon I entirely stopped both chloral and morphia, and she never seemed to miss them. On Dec. 11th, when the treatment was commenced, she weighed 5 st. 9 lb. On Jan. 20th she weighed 7 st. On Jan. 25th she walked downstairs, and went out for a drive, and from that time she went out twice daily. She complained of no pain of any kind, and, although she wore a Hodge, she did not seem to have any uterine symptoms. On Feb. 1st she went to the seaside, looking rosy, fat, and healthy, and has since returned to her home in the country, where she remains perfectly strong and well. A few days ago she came to town, a long railway journey, on purpose to announce to me her approaching marriage.

CASE 3.—My third case differed in many respects from the first two, since the patient was not in the state of extreme nervous prostration from which the others suffered. She was not, like them, excessively emaciated, and she was able to consume a fair amount of nourishment. It was, indeed, a case of pure hysteria of an aggravated form, and its cure was, I believe, chiefly due to isolation, and to moral pressure brought to bear on the patient. I commenced its treatment with considerable hesitation, and relate it chiefly with the view of showing how much such cases are influenced by a morbid craving for sympathy, and benefited when this is not within their reach.

Mrs. ——, aged twenty-six, was sent to me from one of our colonies with the following history. She had had bad labours, followed by bearing-down, backache, and other uterine symptoms, and had been subjected by various medical men to much local treatment, including the use of pessaries, constant cauterisation, and the like, most of which had, I believe, a very prejudicial effect on her. I may say that I was unable to detect any uterine disease requiring topical treatment, although such may no doubt have previously existed. I extract from the full report sent to me by her last medical attendant the following curious account of the nervous phenomena she exhibited. "Her lower limbs are partially paralysed, or, at all events, not under the proper control of her will. She is able to walk a short distance with a very uncertain gait, but the knees, after a few paces, suddenly give way, and she falls to the ground. When sitting quietly her hands are frequently affected with slight spasms, and her lips and eyelids are subject to occasional nervous twitches. Each menstrual period is preceded by violent hysterical attacks. In these seizures the body is violently convulsed, and the exhaustion which has followed has been so marked that I have occasionally failed to detect the pulse. These attacks are also brought on at other than the menstrual periods by any slight unusual exertion." When the patient presented herself in my consulting-room, although supported by her husband, she fell down on the floor six times, in the manner above described, in walking the length of the room, and this was the only way, I was informed, that she had been able to walk for some two years. She was very pale and anæmic, but fairly well nourished. I soon satisfied myself of the hysterical character of these symptoms, but had great dfficulty in inducing the patient to submit to my proposed treatment, especially as to separation from her husband, who had got into the way of constantly nursing and tending her, with a result most injurious to her health. Within twenty-four hours of the treatment being commenced she had a violent outburst of hysterical excitement, which, however, soon subsided on my proposing to dismiss the nurse and give up charge of the case. For ten days everything went on well, food was taken freely, and there was a perceptible increase in size and weight. When, however, faradisation was commenced, it led to a second paroxysm of excitement, the patient writing piteous letters to her husband declaring that she was going mad, and that the agony produced by the electricity was perfectly unbearable. Under my advice he had the good sense to write and tell her that I was perfectly prepared to stop the treatment the instant she expressed a desire that it should be so, but that, as it had been begun, he would not take on himself the responsibility of doing so, and that the decision must be made by her. I then informed the patient that as the object of the electricity was to give strength to her weakened limbs, the moment I was satisfied, by her walking downstairs without falling, that the desired result had been gained, it would, as a matter of course, be stopped. This lady was lodging rather more than a mile from my house, and, to my very great surprise, the next morning after the scene I have narrated, she was shown into my consulting-room, having of her own free will got up and dressed, sent for her husband, and walked without assistance the whole way without once falling. She has since left town apparently quite cured, and I heard from her a few days ago that she was about to start for a prolonged continental tour.

It will be obvious that in this case the massage, diet, and electricity had only a secondary effect as part of a whole that was intensely disagreeable to the patient. Clearly the main factor was the removal of injudicious sympathy, but the case seems to me worthy of record as showing the extreme value of a determined effort to break through habits of a morbid character, and the importance of trying to make a weakened will exert itself.

CASE 4.—This case is a typical instance of the kind of nerve debility and exhaustion that may be associated with old-standing uterine disease. It was placed under my care by Dr. George Kidd of Dublin, whose account of the case I prefer giving to my own, having his permission to do so. She had long been under his care and that of Dr. McClintock, and the fact that she had been treated by obstetricians so eminent is of itself sufficient proof that all had been done for her that the most advanced science could suggest. I may premise that the patient was a single lady forty-five years of age, that she had never been strong, but had not been completely laid up until 1872, since which time she had been confined to her bed or couch. Dr. Kidd wrote to me as follows:—"Miss —— has been a complete invalid for many years. She suffers from excessive pain during menstruation, and from constant pain in the left side and back, extending down the left thigh and leg, with loss of muscular power in that side. Some years ago I discovered a fibrous tumour growing from the left side of the uterus, subperitoneal, and with a pedicle long enough to allow of free movements. Mr. Spencer Wells cut down on this tumour, and removed it, but without removing either the menstrual pain or the pain in the side. The tumour has grown again in the same situation, and is nearly as large as before, probably one inch and a half in diameter. All the mucous membranes are delicate, and she suffers occasionally from vaginitis and endometritis, and also much from piles and prolapse of the rectum. Miss —— is of a highly nervous and hyperæsthetic temperament, which is probably exaggerated by the isolated life she has been leading, and by the frequent use of hypodermic injections of morphia to relieve pain." I may supplement this account with an extract from a letter from the patient herself, which graphically describes the state of her nervous system. "I can hardly tell you what a deep sufferer and how prostrate I have been. For years I have led a completely sedentary life, always lying; it is the position I am easiest in. My back aches sorely. I am peculiarly sensitive to pain. I spend very restless nights. The pain is often then very bad. I have always a sense of great weariness." I found this lady, as might have been anticipated, pale, anæmic, very wasted, and with her nutrition at the lowest ebb. She had no appetite, and consumed hardly any food, a snipe or the wing of a pigeon constituting, with half a cupful of bread-and-milk, all she took in twenty-four hours. Moreover, she had the morphia crave strongly developed, her maid giving her hypodermic injections of four minims of the pharmacopœial solution ten times, sometimes much oftener, daily, equivalent at the least to six grains of solid morphia; besides which she took draughts of chloral and morphia twice daily. I found the fibroid as described by Dr. Kidd, apparently growing from the posterior wall of the uterus, supported by a Hodge, which seemed to give her some comfort. It will be admitted that here was a case sufficiently bad to test the value of the treatment thoroughly, and, inasmuch as there was a distinct uterine lesion which could not be removed, I undertook it with considerable misgiving. I was, however, encouraged to do so on reflecting that there was nothing *per se* in such a fibroid to cause much suffering, many women having similar outgrowths which in no way affect them, and I hoped that if I could succeed in improving the vital energies and in breaking off the vicious habit of morphia taking, much good might be done. I accordingly isolated her with a nurse, having sent away her maid who had attended her during all her illness. During the first fortnight, or rather more, things went on very badly. It was reported to me that it was quite impossible to administer to her the food that was ordered, the stomach being unable to bear it; the sleeplessness was aggravated rather than lessened, and she was in the lowest state of mental depression, constantly crying and declaring that she could not possibly bear the treatment. On trying to stop the hypodermic injections, violent vomiting supervened, which lasted the whole of one night, but which was immediately relieved when the morphia was again given. At this juncture I was nearly in as great despondency as the patient, and feared that the treatment must be abandoned. On reflecting on a result so different from that which I had observed in other cases, I came to the conclusion that the fault lay chiefly with the nurse, who, although an amiable and willing woman, had neither the intelligence nor the tact necessary for such a case, and who yielded in everything to the wishes and fancies of the patient. I therefore determined to change her, and secured the services of the nurse who had managed my first case, on whose judgment and skill I could thoroughly rely. From that moment everything went on as well as could be wished; nothing more was heard of the food disagreeing, and within ten days my patient was taking three full meals a day, besides her milk and soup, with relish and appetite. She slept all night long, and began rapidly to put on flesh. As a matter of fact, I believe that the first nurse, who had no experience as a masseuse, entirely mismanaged the shampooing, giving practically no muscular exercise, and, as a matter of course, the increased amount of food could not be assimilated. It was quite surprising to note how at the end of a week, with her new nurse, the patient had lost her depression, and had become comparatively bright and very hopeful. The hypodermic injections were gradually lessened in number and quantity; in a fortnight all sedatives were entirely discontinued, and nothing of the kind has been since touched, nor has she any craving for them. It was very curious to watch this patient's progress. From leading a life of complete isolation for so many years she had fallen into a chronic state of dread and alarm, and could not at first bear the idea of meeting any stranger, and was, indeed, somewhat like a prisoner brought into the world after a lengthy imprisonment. Every step in advance was a matter of apprehension to her, and it required much encouragement and persuasion to induce her first to leave her room and walk downstairs, then to go out, and so on; but by degrees all difficulties were overcome. I eventually induced her to remove into one of our largest hotels for the express purpose of bringing her into contact with the life and bustle of such an establishment, and soon she was able to sit in the public room, to dine at the table-d'hôte, to go out for daily drives, and to go to church. She now looks twenty years younger than when the treatment was commenced, and her friends declare her to be almost unrecognisable, which is indeed the fact. For the last month of her treatment she never mentioned her uterine symptoms, and I purposely refrained from inquiring about them. She has now left, accompanied only by a maid, for a trip across the Atlantic, with the object of visiting the Falls of Niagara. Perhaps I cannot better contrast this patient's present and past condition than by again quoting from a letter of her own written as she was leaving town. "I find it impossible to get people to understand the treatment I have lately undergone, but the results have been quite marvellous and speak for themselves. My brother, whom I saw for the first time yesterday, said I am a miracle. I *really* do not know myself, and, although I sometimes have a frightened feeling, I have *much* more self-control, and the aspects of my life have completely changed for me." In a patient of this class it is, perhaps, too much to hope that when left to herself there will be no relapse—time alone can show; but so far at least, the treatment has been successful beyond my utmost hopes and anticipations.

I trust that the cases I have narrated may suffice to show that, by systematic treatment on rational principles, a class of case hitherto found most intractable is really capable of being very satisfactorily dealt with. Of course, it is hopeless to imagine that every case of the kind will be found to improve as much as those I have described, since there must of necessity be many factors in operation, the action of which can never be determined beforehand, which may materially interfere with the desired results. If, moreover, the medical man, and still more the nurse, cannot succeed in obtaining a certain moral influence over the patient, and in inspiring the confidence which is essential, failure will almost necessarily follow. In Case 4 the influence of an inefficient nurse was very distinctly shown, and I should be inclined to say that a really good nurse, of sufficient intelligence to understand thoroughly what is required, and with the necessary admixture of tact, kindness, and firmness, is by far the most important element for success, and it is needless to say that nurses of this stamp are not readily found. Short of complete cure, very material improvement in the condition of such cases may be confidently expected; and, at the worst, even if failure follows, no bad results can possibly attend the adoption of this plan. My own conviction is that Dr. Weir Mitchell has made a most important contribution to practical medicine by the introduction of the method I have been describing, which I trust the perusal of these notes may induce many to try. Beyond doubt the treatment is very troublesome, and requires much care and patience; but in cases so distressing no trouble should be considered a bar to its adoption.

George-street, Hanover-square, W.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

Miss M. A. H. Henery bequeathed £500 each to the Royal Free Hospital, the Middlesex Hospital, the Brompton Consumption Hospital, University College Hospital, and the Hospital for Paralysis, Putney. The Sea-bathing Infirmary, Margate, receives £50 under the will of the late Mr. S. Hindley of Tunbridge Wells. The Grocers' Company has given £200 to St. George's Hospital. Miss Georgina F. Downie, of Appin, bequeathed £500 each to the Edinburgh Royal Infirmary, and the Royal Infirmary and the Western Infirmary, Glasgow.

ON A CASE OF

BELLADONNA POISONING TREATED WITH PILOCARPIN.

By NICHOLAS GRATTAN, L.R.C.P. Edin.,
SURGEON TO THE COUNTY AND CITY OF CORK HOSPITAL FOR WOMEN AND CHILDREN.

The subject of the "antagonism of therapeutic agents" has of late been brought so prominently before the profession that the notes of the following case will probably be read with interest.

Mrs. M——, aged forty-two, drank by mistake a wineglassful of a liniment at 9 P.M. on Dec. 23rd, 1880. Fortunately for her, she had had a hearty dinner about four hours before. She discovered her mistake, and took two teaspoonfuls of mustard in water, with no effect. She walked a short distance into town, purchased an emetic, which she drank, returned home, felt dizzy, her sight going, shadows before her eyes, lost the power of speech, became greatly excited, had convulsions, and vomited slightly, and then lapsed into profound stupor. At 10.45 P.M. I saw her for the first time. Her pupils were widely dilated, not acted on by light; her face was swollen, and of a bluish colour, more especially her lower lip, the mucous membrane of which appeared as if it had been blistered; the pulse was imperceptible in one wrist, almost so in the other; respiration 25. I introduced a stomach-tube, pumped in mustard emetic, and washed out the stomach thoroughly. In half an hour she had vomited freely, sensibility was slightly returning, but she soon lapsed into complete stupor. From this time until 2 A.M. she was treated with cold affusion to the head, and flagellation with a wet towel over the heart. At 2 A.M. I learned from my friend Dr. Harvey (for whom I had sent, as he had ordered the liniment for Mrs. M—— at the dispensary) that she had taken ℥ ii. ʒ ii. of lin. belladon. (B. P.). There being no decided improvement in her condition I determined to try pilocarpin; this I procured at 3 A.M. and subcutaneously injected one-fifth of a grain every fifteen minutes. After the third dose there was a marked improvement; consciousness was evidently returning, her countenance became more natural, her pulse could be distinctly felt, and she was able to raise her hands to her mouth and throat. At 3.45 I administered a fourth dose of one-fifth of a grain; this had a decided effect on both pupils, which began to contract under the influence of light; she was evidently fast recovering; had a drink of tea and milk and was able to speak. At 4.30 A.M. she was so far recovered that I thought it safe to leave her, desiring her friends to send for me should she relapse into her former state. When I saw her again at 10 A.M. she had had a refreshing sleep, from which she awoke saying that she did not remember anything that had occurred. She had had in all four-fifths of a grain of pilocarpin; it appeared to act as a direct antidote to the belladonna and did not cause the least perspiration. She continued to feel slight dizziness for two days with dilated pupils, but was in every other respect quite well. I gave her half a drachm of tincture of opium each night. The third day she had perfectly recovered.

Cork.

ON THE CAUSATION OF ALOPECIA AREATA, AND ITS OCCASIONAL CO-EXISTENCE WITH TINEA TONSURANS.

By JOHN COLLIER, M.D.

Dr. Liveing in one of his works remarks that tinea tonsurans sometimes insidiously produces a smooth, bald patch, and that after a time the hair may grow again on such a patch. In such a case a microscopical examination would probably give negative results, as the disease would have completely exhausted itself. The non-discovery of cryptogams would be no proof that they might not have existed previously, and unnoticed have produced this baldness. Ringworm presenting the usual features might also be present. Now, whilst one observer, taking the *history* of the case as a guide, would describe it as one of tinea tonsurans, another might bring it forward as a curious example of the co-existence of that disease with alopecia areata. But let it be granted that sometimes these two affections do co-exist (and no doubt they do), is there anything inexplicably mysterious in such an occurrence? Suppose a boy who is afflicted with alopecia areata attends a school where there are several of his companions who are affected with ringworm; perchance he wears one of their caps, and thus by contagion the disease is communicated to him. This would therefore be an example of these two diseases occurring together in the same person; yet I apprehend there would not be the slightest etiological significance in such a fact. It cannot be too strongly enforced that there is no connexion whatever between these two affections. Moreover, it is not a very uncommon thing for two skin diseases to exist in the same subject. Cases have been recorded of the co-existence of favus and tinea circinata, of scabies and tinea tonsurans, of chloasma and acne, and even of varicella and psoriasis. Alopecia areata may be regarded as a cutaneous neurosis. Most dermatologists are agreed that it is originated by a lesion of nerve function which takes the form of a disturbance of nutrition, of the formation and reproduction, of hair. Several considerations appear to support this view; thus we often have tingling pain before the baldness appears, and afterwards marked loss of sensation in the patch. Under the microscope the diseased hairs will be seen to be simply atrophied and of a lighter tint than the natural hair. Several cases have also been recorded by Mr. Erasmus Wilson, in which this affection was caused by severe neuralgia. In such cases a paralytic condition of the trophic fibres of the sympathetic is produced; the exhausted nerve yields up its power, to a greater or less extent, and refuses to perform its function. The following examples of alopecia areata, which I have recently met with, will prove interesting and suggestive.

Case 1.—H. H——, a stalwart young fellow, last August received a blow from a cricket-ball on the right temporal region. After his recovery from this accident a patch of alopecia areata made its appearance about one inch above the seat of the blow. Subsequently the hair grew again.

Case 2.—R——, a schoolboy, aged twelve years, received, during a fistic encounter, a swinging "right-hander" over the left ear. This brought on intense neuralgia, from which he suffered for a fortnight, when one morning he discovered that he had not only lost the neuralgia, but also some of his hair. A large patch of alopecia areata was formed on the left parietal region. After being treated for about a month the hair was reproduced, but, curious to relate, it was of a grey colour, and presented a marked contrast to that which surrounded it.

Case 3.—T. A——, aged nineteen years, presented a typical picture of Addison's disease. The mulatto pigmentation of the skin, the weak action of the heart, the vomiting and diarrhœa, nervous depression and intense asthenia, rendered the diagnosis only too certain. A post-mortem examination was not allowed. The interesting point about this case was that at the commencement of the disease two extensive patches of alopecia areata appeared on the occiput. Only a short-lived lanugo was produced on these. Dr. M'Call Anderson has pointed out that this affection not unfrequently exists in Addison's disease. This is what one would expect, as it is now generally considered that the latter affection is caused by a lesion of the sympathetic nervous system.

Case 4.—F——, aged forty-five years, was suddenly reduced, by unsuccessful speculation, from a state of comparative affluence to one of poverty. On recovering from the shock, he found that the right ear was hyper-sensitive to sound. After a short time several patches of alopecia areata were noticed; these speedily enlarged, and very soon complete baldness was the result. The eyebrows also disappeared. Active treatment produced negative results.

These four cases present gradations in severity; for in the first case the hair grew again; in the second it was reproduced, but was of a different colour; in the third a few fine hairs appeared; while in the last example there will be everlasting alopecia. If the cause of the affection be local rather than general, there is a better chance for the growth of new hair. We learn from Goltz's well-known "tapping" experiments (vide Ziemssen's Cyclopædia) how comparatively slight mechanical irritation of the abdominal viscera suffices to excite a disturbance of the functions of the abdominal nerves and ganglia; therefore it is not surprising that, in Cases 1 and 2, a blow should cause a lesion of the trophic filaments of the sympathetic which supply the scalp. It is not improbable that, if we inquired into the history of every case of alopecia areata, we should find the cause to be essentially nervous in origin.

Lincoln.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

KING'S COLLEGE HOSPITAL.

ON Saturday last among the cases operated on were two of special interest. The first was the removal by Mr. John Wood of the left scapula from a young girl from whom the upper limb had been removed five months previously for sarcoma. This is the third time Mr. Wood has removed the scapula; his first case was recorded in "Mirror of Hospital Practice," Feb. 27th, 1875. The next case was that of an excision of the upper end of the right femur from a man who had suffered from hip disease for many years. After removal of the great trochanter a fragment of dead bone, the size of a filbert, and evidently the remains of the head of the femur, was discovered embedded in the acetabulum, and removed with an elevator. In some of its clinical and pathological features this case bore some resemblance to one under the care of Mr. Smith last year, and recorded in the "Mirror of Hospital Practice" on January 8th last. In that instance a large piece of dead bone was found during excision of an elbow-joint to have been the cause of inflammation and suppuration in the joint after fracture of the internal condyle.

SARCOMA OF THE SCAPULA; REMOVAL.

(Under the care of Mr. JOHN WOOD.)

For the early notes of this case we are indebted to Mr. Hugh Smith, surgical registrar.

The patient, Sarah Ann F——, aged seventeen, was originally admitted into King's College Hospital, under the care of Mr. John Wood, on January 9th, 1881. She was then well nourished, but spare, and somewhat pallid. Six months before admission she felt pain in the left shoulder; three months later swelling was noticed in the same place. On admission the outer and anterior aspects of the upper fourth of the left humerus were seen to be the seat of a rounded tumour. The skin over it was tense, the superficial veins were enlarged, and the mass felt hard, but slightly elastic on pressure. On January 15th amputation of the left arm at the shoulder-joint was performed under Listerian antiseptic precautions. Some processes of the tumour extended into the supra-spinatus and infra-spinatus fossæ, but there was no evidence of any new growth springing from the scapula itself. The muscles arising from the scapula and passing to the head of the humerus felt rather harder than normal, and so were cut off as close to the former as possible. Microscopical examination of the tumour: Spindle-celled sarcoma, with a few round cells scattered throughout the growth.

On the 20th the wound in the skin had healed, and on February 26th the patient was discharged, apparently cured. She was advised to attend the hospital from time to time, in order that the parts might be closely watched. She did not, however, return till about the middle of May, when a large tumour was found, apparently involving the whole of the scapula. The patient stated that she first noticed pain about the shoulder six weeks before.

The tumour seemed to involve the whole of the scapula, and was of semi-spheroidal shape. Across its centre the skin was nodulated, discoloured, and adherent, but there were no enlarged glands in the neighbourhood. The tumour, which was very hard and dense, was freely movable on the chest walls. The patient was kept in the hospital a few days, in order to prepare her for the operation, which, as already stated, was performed on Saturday last in the following manner, with strict antiseptic precautions (Listerian).

The patient, having been placed under the influence of an anæsthetic, an incision was made through the skin across the clavicle about its middle. This bone was then divided by means of a small saw and cutting pliers. The subclavian and the posterior scapular arteries were compressed by Mr. Royes Bell through this incision, while Mr. Wood extended the incision vertically downwards to the level of the lower border of the scapula in front. Two incisions were then made across the tumour, inclining upwards and backwards from the vertical incision, so as to include part of the cicatrix of the previous operation and those portions of the skin that were implicated by the growth. The upper and lower flaps thus formed were then dissected up from the growth, which, with the morbid scapula, was then rapidly removed from its connexions to the chest walls by cutting its attachments from before backwards. The serratus magnus and adjacent muscles did not seem to be implicated. Fifteen vessels were secured with carbolised catgut, and after the insertion of drainage-tubes the skin-flaps were neatly brought together, and fixed by deep and superficial sutures of wire and silk. The wounds were covered by "protective," and then enveloped in eucalyptus gauze. Thanks to Mr. Bell's complete control of vessels, very little blood was lost, and the patient seemed to bear the operation fairly well. Unfortunately, however, she did not rally from the operation, and died the same evening.

EXCISION OF THE UPPER END OF THE FEMUR.

(Under the care of Mr. HENRY SMITH.)

The patient, a man aged twenty-six, had had disease of the right hip since childhood, and when admitted into the hospital some weeks since was suffering from all the symptoms of advanced hip disease to an extreme degree. The limb was shortened, adducted across the other thigh; the buttock was much altered from its natural state, and was riddled with sinuses discharging much matter. The pain was very severe. The general disturbance was great, the patient suffering much from night sweats and cough, and some pain in left side of the chest; indeed, the latter symptoms were such as to lead Mr. Smith to suspect pulmonary tubercle, and an operation was postponed until repeated examinations had failed to detect any serious lung mischief. In the performance of the operation, which was of unusal difficulty, the section of the bone, which was extremely dense, was made through the trochanter, and when this had been removed it was found that the head of the bone had almost entirely disappeared, and on carefully examining the acetabulum a portion of necrosed bone about three-fourths of an inch in extent was found impacted as it were in that cavity. It was readily removed by an elevator, and was ascertained to be the remains of the head of the femur.

Mr. Henry Smith remarked that this case showed how desirable it was to remove the trochanter in this operation. As it facilitates the exploration and removal of dead bone from the acetabulum at the time, and obviates the possibility of any portions of loose bone being retained during the after-treatment. He had no doubt that in this case the necrosed head of the femur had been retained in the acetabulum for years.

GREAT NORTHERN HOSPITAL.

A CASE OF FRACTURE OF THE SKULL; CURIOUS MUSCULAR TWITCHINGS AND SPASM; DEATH.

(Under the care of Mr. ADAMS.)

FOR the following notes we are indebted to Mr. James MacMunn, late resident medical officer.

A collection of cases of traumatic and localised brain lesion followed by definite muscular disturbance may be serviceable in elucidating the physiological anatomy of this organ.

S. J——, aged four years, was admitted in October, 1879, suffering from fracture of the skull, the history being that the child had a fall on its head down an area some twenty feet in height.

On admission one hour after the accident the child was in a state of collapse. The breathing was eight per minute and irregular; the pulse 60, also irregular. The face was pale, the surface cold, whilst complete relaxation of the voluntary muscles was present. Unconsciousness existed, not, however, to irritation; thus when ammonia was held to the nostrils the child turned its head partly around as if to avoid the fumes. The pupils were dilated and reacted imperfectly. There was no stertor. The progress for a time tended towards reaction, the pulse rising in frequency and becoming regular, but signs of cerebral irritation soon supervened, whilst the symptoms worthy of notice were: 1st. Extreme and persistent flexion of the forearm, with clonic jerking of the muscles (120 times per minute), causing the hand to be bent upon the forearm and the latter upon the arm to the fullest extent. 2nd. A boring of the index-finger of the same hand in the eye of the corresponding side. The clonic spasms were powerful, and when the limb was forcibly extended and then released it immediately assumed its peculiar attitude again. The legs and right arm, as indicative of the cerebral irritation, were also slightly flexed by a tonic contraction, but not in the least disturbed by any jerkings. Convulsions came on at times most marked in the left side, and aggravating for some time afterwards the jerking in the left arm. The child could not swallow; the eyes, examined ophthalmoscopically, showed in the left eye comparative arterial emptiness; both pupils contracted to artificial light, the movement being, however, sluggish, but with no appreciable difference. There was more dilatation of the right than the left pupil. Blood was effused into the left upper lid, and was both subconjunctival and subcutaneous. The pulse rose in frequency, and diminished in force; the surface grew cold, and the patient died thirty-six hours after admission, in spite of the means taken to try to prolong life. Careful examination failed to reveal any external signs of fracture beyond those already given; indeed there was no appearance of contusion either, the child having fallen on soft ground. The necropsy showed fracture in the left side, extending from near the eminence of the frontal bone downwards, and then backwards through the orbital plate, and terminating two lines to the outer sides of the anterior clinoid process; second, a large extravasation of blood lying on the posterior part of the left frontal and the anterior third of the parietal lobes extending in a diminishing volume downwards to a rent in the ophthalmic artery. There was blood effusion into the sheath of the optic nerve. Not the least laceration of brain substance was present. There was no flattening, no lesion of the convolutions on the right side. The extravasation did not at any part extend beyond the mesial lines of the base of the brain, nor within two inches of the longitudinal fissure above and to the side.

There was therefore in this case a definitive lesion of a cerebral hemisphere, an irritation caused by blood effusion expressing itself in a marked rigidity and clonic spasm of the muscles of the arm of the corresponding side, and this in the absence of any right-sided brain lesion, direct or transmitted. Had the patient been an adult it is probable that paralysis would have existed instead of spasm, but this paralysis would be where the spasms were, for, of course, the tracts by which impulses travel are the same at all ages. Again, were the operation of trephining decided upon, which was contra-indicated by the child's low state, it would have been done on the right side—i.e., opposite to the spasms and convulsions—and the extravasation would not be found.

Advertence may be made to another case of fracture of the skull, which was admitted to the Great Northern Hospital about the same time as the foregoing. It was that of a man who suffered from simple melancholia and hallucination of vision, subsequent to, and evidently dependent on, a depressed fracture just over the angular gyrus, and including a portion of the supra-marginal lobule.

L'HOPITAL CANTONAL, GENEVA.

OPERATIONS FOR THE REMOVAL OF THE THYROID BODY IN GOITRE.

FOR the following notes we are indebted to Dr. Alfred Wise:

CASE 1.—Aged sixty-six. There was no family history of goitre in this case. She said she had always drunk wine, and but seldom drank water. She attributed her goitre to carrying heavy loads on her head. She first noticed the swelling twenty-eight years ago; it had gradually increased in volume without giving rise to pain or much inconvenience. She had never been under medical treatment. At the inferior part of the neck was a voluminous tumour, situated anteriorly—circumference at the base, 43 centimetres; vertically, 23 centimetres; transverse, 29 centimetres. The tumour was movable, elastic, fluctuating, and gave the impression of a large sac with thick walls, having hard patches of a cartilaginous material in their texture. Pulsation could be seen beneath the skin. The inferior part of the mass descended a little below the notch of the sternum, and on the left side passed under the sterno-mastoid. The sterno-hyoid and sterno-thyroid muscles were in front of the tumour, forming little cords below the skin at their points of insertion above. No signs of compression of any organs of the neck presented themselves. The pupils were normal.

On March 14th Professor Julliard made a free vertical incision over the middle of the tumour, the enucleation of which was easy until the deep attachments were reached. A large number of veins and some arteries were ligatured with catgut as soon as divided. The internal jugular was in close relation with the tumour for eight or ten centimetres, being enlarged to the size of the thumb and pulsating with each respiration. The adhesions to the trachea and larynx were broken down with the fingers, aided by scissors, directors, &c., and the mass removed without much loss of blood. The goitre was found to be developed from the left lobe of the thyroid body; and the right lobe being hypertrophied, was removed also. A decalcified bone drain was introduced into the wound, the edges were brought together by catgut sutures, and dressed with protective oil-silk; sponges squeezed out in carbolic lotion; thick layers of muslin (treated in the same way); gutta-percha tissue over this, and muslin bandages over all. The large tumour weighed 1200 grammes, and consisted of a cyst of colloid matter, encapsuled by tough walls of six to eight millimetres in thickness; it presented patches of cartilaginous material and small points of rough calcified irregularities. The smaller tumour weighed thirty grammes and presented the aspect of a parenchymatous goitre without cysts. Carbolic spray was not used in this operation, and chloroform was given sparingly. The temperature before operation was 36·2° C., evening 37·3° C.—15th: Morning temperature 36·7° C., evening 38·0° C.—16th: Morning temperature 37·0° C., evening 38·0° C. Fresh dressings were applied.—17th: Morning temperature 37·2° C., evening 37·9° C. General condidition was satisfactory.—19th: The wound was united by first intention except at the orifice of the drain. Dressings were discontinued and a piece of strapping placed over the opening.—28th: Since the last note the patient has been confined to bed again with pain, fever, and other symptoms indicating the formation of a large abscess in the neck. This has been opened and about twenty-five ounces of healthy pus evacuated, the temperature falling to 36° and 37° C.

3rd April: The discharge of pus was diminishing, and the patient was progressing favourably.

CASE 2.—Aged nineteen. In this case there was a family history of goitre, the mother and two sisters of ten and thirteen years of age being affected. The patient stated that the goitre commenced when she was eleven years old, and now became larger and harder at each menstrual period. The swelling was as large as a fist, and was situated on the left side of the median line more than on the right. It measured twelve centimetres by fifteen, and was movable, elastic, and fluctuating. No vessels were seen on the surface, and the tumour followed the movements of deglutition. On the 4th of March the patient was put under chloroform, and Professor Reverdin extirpated the whole of the thyroid body. The operation occupied three-quarters of an hour, some difficulty being experienced from the attachment of the tumour to the trachea and a number of veins requiring ligature. The patient suffered a good deal from cough and dyspnœa caused by irritation of the trachea, and was very feeble after the operation. A decalcified bone drain was inserted, the wound sutured with catgut, and dressed antiseptically. All the proceedings were carried out under carbolic spray. Temperature 38° C. in the evening.—5th: Evening temperature 39·7° C. in the rectum.—6th: Temperature 38·6° C.—8th: Temperature 38·2° C. Fresh dressings were applied. The wound had united by first intention, with the exception of the orifice where the drain had been absorbed. Cough and painful deglutition were diminishing.—10th: Temperature 37·9° C. in the axilla. Dressings reapplied. Firm union had taken place, with the exception of the orifice left by the drain, from which a small quantity of thick and slightly fetid pus escaped.—14th: Temperature 37·5° C. The patient had been up for some days.—17th: The secretion of pus had not ceased, but was without bad odour.—27th: The quantity of pus had been diminishing since the last note, and it now caused but little inconvenience. There was a firm healthy cicatrix above the fistulous opening, and the patient was able to assist in the work of the ward.

Remarks.—Professor Reverdin has operated 13 times for the extirpation of goitre, and Dr. Auguste Reverdin 4 times. Out of these 17 cases 3 have died—viz., 1 case of calcified, suffocating goitre, 1 case of ordinary suffocating goitre, and 1 case of cancer of thyroid, with thrombosis of jugular vein. Out of the remaining 14 operations 12 have healed by first intention, sometimes with little fistulæ lasting for a time, and 2 have healed by second intention.

Reviews and Notices of Books.

Minor Surgical Gynæcology. By PAUL F. MUNDÉ. New York: Wood and Co.

WHEN we first saw the title of this work we became curious to see its inside, because it appeared to us that there was no subject on which it would be more difficult to write a *manual* which would be useful to the student, the general practitioner, and the patient (for some consideration should be shown her), than minor surgical gynæcology. And this appeared to be the case for two reasons: (1) Inventive genius has been so marvellously prolific in this field of medicine that, in order to do justice to the innumerable tools of all kinds which have been or are still used by some gynæcologists, the work would necessarily degenerate into an illustrated catalogue of instruments. (2) With regard to many of the operations characterised unfortunately by the term "minor" which are practised upon the pelvic female organs, opinions so diverse are held that it would be impossible to discuss them in an adequate manner in a manual. The first of these difficulties the author appears to have felt, for he states in the preface: "I have endeavoured not to give the book the appearance of an instrument-maker's catalogue." Of the second, however, in so far as we have been able to discover, he appears to have been utterly unconscious.

The work is divided into two parts: the first, which forms about one-third of the whole, treats of Gynæcological Examination. This is again subdivided into chapters on verbal examination, methods of local examination, postures for examination, examination couches, examination without instruments, and examination by means of instruments. All these subjects are treated of fully, and the student who has mastered this part of the work will have the means at his disposal for diagnosing the conditions to be met with in the female pelvis. This part contains one hundred illustrations, of which nearly forty are of vaginal specula or drawings to explain their use. It is not easy to find the object of some of the illustrations—indeed, we have quite failed,—while many others would find their appropriate place in an "instrument-maker's catalogue" only.

The second part treats of "Minor Gynæcological Manipulations and Applications." It is in the writing of this part that the second difficulty mentioned would or should be felt. Curiously enough, however, the author has selected to describe several operations, such as division of the cervix, excision of the lips of the cervix, applications to the endometrium, the value and place of which have not yet been definitely settled, while he has omitted small operations, such as removal of cysts of the vulva and of the vagina, of extruded polypi, and division of an imperforate hymen, about which opinions are in the main agreed; so that much space is devoted to the description of operations of doubtful value and necessity—operations which are, it is true, practised and extolled by many, but are, on the other hand, rejected by others as unnecessary, or often productive of mischief.

To displacements and their treatment by pessaries, both vaginal and intra-uterine, the space and number of illustrations devoted are utterly beyond their importance. There are more than seventy drawings illustrating these instruments, many if not most of which have no peculiar value outside the imagination of their inventors. Indeed, these instruments seem to serve no good purpose except to exhibit in a very painful manner the unscientific character of our knowledge of diseases of women. Some of the illustrations in this part of the work are evidently no more than diagrams. They have not been drawn from nature; and when we compare them with what is found in nature we find them to be incorrect. We refer more especially to the illustrations of the uterus in a state of flexion. In all of these the cavity of the uterus is shown dilated. Now, there are several specimens of the flexed uterus preserved in museums, and accurate drawings of some of them have been made and published, but in none of them is the canal in a condition of dilatation. It is true that most of the illustrations bearing on this matter are not original to the author, but copies from the works of others, but they have been made according to a preconceived theory, and not from specimens. There are some things in the work which we prefer to pass without notice.

There are many matters described in it about which all are agreed, and in so far it is a sound guide to the student; but, as we have pointed out, and this is of far greater importance, the work contains descriptions of manipulations and operations about the value of which there is much doubt; and the one thing certain about them is that they are not unassociated with serious danger, and consequently they should be had recourse to but rarely. In some cases they have proved fatal, while in others they have been productive of permanent injury, rendering their subjects life-long invalids. Operations of this kind, in which benefit is doubtful and the risk great, should not be undertaken by the advanced student, nor indeed by anyone who is not perfectly acquainted with the conditions in which they may justifiably be had recourse to, and fully cognisant of their dangers. Could we regard the female pelvis as a storehouse for instruments or a laboratory for physiological and pathological experiment, we would heartily recommend the work before us as one of the best of manuals; but as we regard the patient as an important, and indeed the only important, factor in the operation, the sole object of which should be her benefit, we cannot approve the frequent recourse to means associated with so much danger. We think the author has attempted an impossible task in writing a manual on minor gynæcological surgery which would prove beneficial to student, general practitioner, and patient. The subject is at present incapable of such treatment. Although the descriptions of manipulations and operations in the work are well done, yet this is not sufficient. It is as important to know when to operate or to introduce a pessary as to know how. This knowledge cannot be gained by the perusal of a short manual descriptive of operations, but by study of the larger works on gynæcology, together with observations at the bedside. In minor gynæcological surgery the knowledge how to operate without knowing when is far more likely to prove injurious than no knowledge at all, or than mere expectant treatment. Although this work, in our opinion, lacks some of the most important qualities a manual should possess, yet we cannot withhold our admiration for the diligence, method, and ability shown in its compilation. We can only regret they were not directed to a worthier object.

Archives of Dermatology. Edited by Dr. BULKLEY. Vol. VII., No. 2. New York: Putnam's Sons.

WE have much pleasure in directing renewed attention to this very excellent publication, which is, since the discontinuance of the *Journal of Cutaneous Medicine and the*

American Journal of Syphilography and Dermatology, the only scientific journal published in the English language devoted exclusively to skin and venereal diseases. It continues to afford valuable assistance to those who give special attention to these classes of disease, and, to our mind, in a greater degree than the similar journals in France, Italy, and Germany; but it is further the aim of the editor to so enlarge its field of usefulness as "to serve as a communication between the specialist . . . . and those in general practice." Dr. Bulkley has been fortunate in the many able collaborators who have assisted him in his endeavours, and we are glad to see that two of the younger English dermatologists, Mr. Morris and Dr. Colcott Fox, have now been added to his staff—the former taking the duty of digesting the recent literature of the anatomy and physiology of the skin, and the latter therapeutics and such general topics as medicinal rashes, statistics, baths and mineral waters, &c. We hope the "Archives" will meet with the support it deserves amongst British practitioners.

The Life and the Poetical Works of John Critchley Prince. By R. A. DOUGLAS LITHGOW, LL.D., M.R.C.P. Edin., F.R.S.I., &c. In three Volumes. Manchester: Abel Heywood and Son. London: Simpkin, Marshall, and Co. 1880.

WE ought sooner to have noticed this work, and we can only do so now with much more brevity than we could wish. The work has this double interest for us, that it contains the record of a human life which, despite its poverty and its sins, has great and beautiful lessons; and, secondly, that the life is written, and the poems are edited, by a member of our profession, with a sympathy and an appreciation of genius which are never more fitly placed than in the medical man, to whom nothing is foreign that is human. To take time from a busy professional life to write the life of a working man, born in 1808, who thought himself a poet, and wrote poems that fill two considerable volumes, is not a proceeding that would commend itself to all medical men. But Dr. Lithgow has so done his work as to lay all lovers of poetry and all lovers of men under considerable obligation. We should, indeed, have noticed these volumes weeks ago but for the fact that whenever we have taken them up we have found a sort of fascination either in the poems themselves or in the life of Prince as told by Dr. Lithgow. Prince was undoubtedly a poet of no mean genius, and, though he struggled with poverty such as working men nowadays know or need know little of, this very poverty and struggle enhance the value of his poetry and our admiration of it. We commend his poems and Dr. Lithgow's "Life" to our readers—the one for their beauty, their melody, and their healthiness of sentiment, and the other for its great sympathy and its truthful narration of a life too common in its misery, but too rare in the thoughts and faculties by which even misery is elevated and mitigated.

Syllabus of Materia Medica for the Use of Students, Teachers, and Practitioners. By ALEXANDER HARVEY, M.D., and ALEXANDER DYCE DAVIDSON, M.D. Fifth Edition. London: H. K. Lewis. 1881.

THE popularity of this little book is attested by the appearance of the fifth edition. It is practically a list of the preparations of the British Pharmacopœia, and is sufficiently compact to go into the waistcoat-pocket. It is a convenient book of reference to the practitioner, and we fear also a convenient cram-book for the student. The attempt to assign the relative value to different preparations and drugs, by means of numbers, is retained, but seems to us of very doubtful utility, giving, where it does not mislead, no useful information.

New Inventions.

RESPIRATOR FOR USE AFTER TRACHEOTOMY.

DR. ARNISON, of Newcastle-on-Tyne, has designed a respirator to be attached to the front of a tracheotomy tube. The respirator is intended to obviate the risk of pneumonia, which is one very fertile cause of death after tracheotomy, and is probably caused by breathing air which has not been warmed and moistened by traversing the natural air-passages on its way to the lungs. It is on the principle of the ordinary respirator, and consists of six circular plates of fine wire gauze enclosed in a box. The box slides into a rim which projects from the front of the neck-plate, and it is so made as to be easily removed, not only by the surgeon or nurse, but also by the patient himself if he should find any impediment to breathing through fouling of the plates. The lid of the box (an open ring) takes off, and the plates can be taken out and cleaned, being quite free and not attached to each other. It has been tried on a patient of Dr. Drummond in the Newcastle-on-Tyne Infirmary, and it was not found necessary to clean the plates oftener than once in two or three days. A disc of carbolised gauze catches any discharge coughed up, and so prevents fouling. It is evident that the respirator cannot be used where there is persistent cough with expectoration, which would rapidly foul the plates. It is only adapted to cases where cough is absent or comparatively quiet, in which it may probably be prevented or relieved by breathing warm air, moisture being supplied by a steamer as usual. The tube is the ordinary tracheotomy tube, and is made in two sizes, one respirator fitting both. The respirator has been made for Dr. Arnison by Messrs. Weiss and Son. The only suggestion we would offer is that it would be an improvement if the box and plates could be made still lighter than they are, so as to lessen the weight of the respirator.

MESSRS. SOUTHALL BROS. AND BARCLAY'S SURGICAL APPLIANCES.

THE above firm are the manufacturers of some very useful materials for surgical purposes. They prepare a Dextrinised Millboard which is sold in strips and angles; it is very light and firm, and yet brittle enough to be easily broken into required lengths. When soaked in boiling water it becomes pliable in a few moments, and is then readily moulded to a part, and quickly again becomes hard, forming a very light, cleanly, and sufficiently rigid splint. We have also made a trial of their Antiseptic Pads, formed of absorbent cotton-wool enclosed in absorbent gauze, and the whole impregnated with salicylic and carbolic acids. Their absorbent power is extremely valuable, and they are a very simple and cleanly dressing for open and discharging wounds. They are made of various sizes, and some are well adapted for the lying-in room. The Antiseptic Absorbent Bandages may be useful in some particular cases. Of Southall's Antiseptic Elemi Plaster or Hospital Strapping we can only say that after a fair trial we have found it superior to any we have hitherto met with. It is very pliable, adheres without heat or moisture, is cleanly to use, does not crack off, and does not adhere too closely. Its antiseptic property may be of some value when applied directly to wounds, but whether this is so or not, its other excellences enable us to recommend it with confidence.

TINNED-WIRE STILETTES.

MESSRS. SAMUEL LAW & SONS have submitted to us some specimens of their fine tinned-steel-wire stilettes for hypodermic syringes. For strength and elasticity they far surpass those generally supplied with the syringes, and are really of use in clearing the fine tubular needles of dirt or crystallised metalloid. Similar wire of larger gauges can be utilised for the stilettes of catheters, &c.

THE LANCET.

LONDON: SATURDAY, JUNE 11, 1881.

THE high percentage of rejections at the various examinations recently held at the Royal College of Surgeons of England is of grave significance and importance to everyone interested in medical education. Some critics (perhaps unsuccessful and disappointed teachers) have indulged in angry comments on the general character of the examinations conducted by the authorities of the College, and have even impugned the competency of some of the examiners. This pique is, perhaps, only natural. The exigencies of the examination system drive teachers and examiners into open and avowed antagonism. There is constant and incessant strife over the merits of the pupil and candidate. Teachers and students, when unsuccessful, are apt to imagine that the examiners are crotchety, capricious, and unfair, while the examiners, when the rejections are high, will not hesitate to declare the candidates are ill taught and badly prepared. Considering that the oral parts of the examinations at the College are open to Fellows of the College, and to other members of the profession properly introduced, it would, at first sight, seem easy to discover the meaning and reason of this high rate of rejections. The matter is not, however, so simple, because an important element is wanting. The quality of the examination and the character of the examiner may be determined, and a sufficiently correct judgment may always be formed of the fitness of a candidate, but there is no means of discovering the merits of the absent teacher whose business it has been to superintend the candidate's training and education. In the hope of obtaining some clue to the great number of rejections we have repeatedly visited the oral examinations for the Membership as well as for the Fellowship, and we will state at once that we entertain a very strong opinion that in a large number of instances candidates are very imperfectly trained, and not a few have evidently undergone no sort of preparation for examination. This is most noticeable at the pass examination for the membership, and least noticeable at the first examination for the membership. The conditions of the Fellowship examination are peculiar, and do not materially affect the question we are now considering—namely, the average education of medical students.

No one, we imagine, will dispute the statement that the first examination, or examination in anatomy and physiology, is a more trying ordeal for the young student than the second, or pass examination; and yet, as a rule, candidates acquit themselves better at the first examination than at the final. We would go so far as to say that even at the pass examinations weak candidates are, usually, better acquainted with surgical anatomy than with practical surgery and surgical pathology. Indeed, it is not uncommon to see a candidate familiar with all the superficial markings and "landmarks" of surgical anatomy, but ignorant of many of the rudiments of practical surgery. The obvious explanation of this remarkable difference is that students are, nowadays, taught anatomy and physiology systematically, and have fairly good facilities for practical study. With practical surgery and surgical pathology, on the other hand, the reverse obtains. To be present at the practical part of the pass examination for the membership is often a melancholy occupation. Many candidates seem to have no notion as to how they should proceed to examine a patient. At a recent examination it was not rare to find candidates ignorant not only of the differences between hydrocele and orchitis, or hydrocele and hernia, splay-foot and suppuration of the tarsal articulations, enlarged bursa and periosteal swellings, or enlarged bursa and fatty tumour, but ignorant also of the methods of physical examination by which those differences might be discovered. Whether the fault be his own or his teacher's, a candidate has not been trained who cannot apply any other test to a hydrocele, or orchitis, or hernia than balancing the enlarged scrotum on the flat of his palm, who examines for fluctuation by prodding a swelling with the tip of his middle finger, who is unable to apply any other test than ocular inspection to a doubtful tumour, and who does many other things that candidates at the College are often observed to do. All this implies absence of practical training. There is in our medical schools no lack of lectures and no scarcity of demonstrations, such as they are, but there is an urgent need of larger opportunities for practical training in clinical medicine and surgery. As no one can acquire skill in practical chemistry or physiology by means of lectures alone, and without practising experiments and manipulations in the laboratories, so no one can become a skilled medical practitioner without actual personal labour in the various departments of a hospital. There is reason to fear that in straining after a transcendental pathology and an over-elaboration of physical aids to diagnosis, the student is not taught the rudiments of his art. This must be patent to anyone who will take the trouble to visit the College examinations, especially during the off season.

We have no desire to pose as apologists for any body of examiners or any examinations, nor do we wish unduly to disparage the candidates. We wish merely to express the conviction based upon a large experience—namely, that as regards practical surgery and surgical pathology, the medical student is at best but imperfectly trained, and at worst he is not trained at all. Nor will this be a matter of surprise when we consider the difficulties of providing dresserships and clinical clerkships for all the pupils at a large school. Even at the largest hospitals there is a dearth of clinical offices compared with the number of applicants, while at the smaller hospitals many students have practically to go without dresserships. From some hospitals many students are compelled to present themselves for examination without any other knowledge of practical surgery than they have been able to acquire while writing prescriptions for the out-patient surgeon, or in opening once or twice abscesses in connexion with impetigo of the scalp, or occasionally strapping an ulcerated leg. Some remedy for this unsatisfactory state of things will have to be found. One way out of the difficulty might be to adopt a proposal made some time ago, to open up the workhouse infirmaries for clinical instruction to medical students. There are doubtless many drawbacks to this plan, but probably not more than to any other. It would, however, be necessary that the authorities of the schools should exercise full and efficient control over such extra-academical hospitals.

◆

AMONG the most important recent additions to our knowledge of the pathological changes which attend and characterise inherited syphilis is that of the affections of the growing extremities of the bones which leads to the separation of the epiphyses. It is not, indeed, a new discovery. VALLEIX, in 1835, described an instance of separation of the epiphyses, with suppuration and with overgrowth of the periosteum, in a newly-born child, and recognised its dependence on inherited syphilis, but the observation remained isolated for thirty years, until, in 1864, RANVIER and others published some additional examples of the change. Our present knowledge of the subject, however, dates chiefly from the careful account of it given by WEGNER in 1870, to which important new facts have been added by PARROT, TAYLOR of New York, GOODHART, and BARLOW. The affection of the ends of the long bones has lately been carefully studied by HEUBNER and VERAGUTH, whose papers appear in the last number of the *Archiv für Path. Anatomie.*

WEGNER regarded the change as an inflammatory irritation commencing in the deepest layer of the cartilage, and extending from this to the bone, while WALDEYER, KÖBNER, and PARROT consider that the bone is the seat of the primary change. The view of WEGNER has been upheld by HAAB, who described a peculiar fissuring of the cartilage, which he considered to be the initial change, and to constitute a primary syphilitic chondritis, and this conclusion is now confirmed by VERAGUTH, from a careful examination of a well-marked case. HAAB described finely granular linear degenerations extending through the cartilage, but VERAGUTH found in addition a peculiar fibrillation of the cartilage which seemed to be the immediate cause of the cleavage. It is probable that these fibres are not of new formation, but exist normally. According to TILLMANNS and KASSOWITZ, they may be rendered visible by the maceration of thin sections of normal cartilage in dilute nitric acid, or in a solution of chromic acid, and have then precisely the arrangement which the syphilitic process discloses. They interlace in all directions, but in the proliferating zone there is a preponderating arrangement in parallel bundles. Hence, according to VERAGUTH, the first step in the pathological process is that under the influence of the virus in the blood of the syphilitic child there occurs an excessive formation of vessels in the cartilage, and a corresponding overgrowth of the cellular elements. The change is greatest in the proliferating zone, and soon assumes a distinctly inflammatory character. *Pari passu* with this productive activity of the cells a retrograde process occurs in the intercellular tissue. The cementing substance between the fibrillæ becomes softened, or as it were dissolved, and the solidity of the cartilage is lessened in consequence, especially in the proliferating layer, in which the parallel arrangement of the fibres renders the effect of the change in the interfibrillar material the greater, and ultimately permits the occurrence of the parallel fissures which then extend through to the perichondrium. The cells increase in number by proliferation, and to them are added numerous lymphoid elements which wander in from adjacent vessels. Several observers have described a transformation of the medulla of the bone into granulation tissue, and the growth of this tissue into the fissures in the cartilage. This was not present in VERAGUTH'S case; many of the vascular canals of the cartilage contiguous to the growing papillæ of the medulla contained spindle-shaped and angular cells, but not in sufficient abundance to suggest an actual ingrowth of the medulla, so that the latter must clearly be regarded as an after-effect, the result of the fissuring, and not its cause. Some morbid changes were found in the bone itself, but these were of a degenerative character—fatty degeneration of the cells of the medulla, deficiency of osteoblasts, and abundance of giant cells,—and are to be regarded as secondary to the affection of the cartilage, which is thus, as HAAB asserted, a primary syphilitic chondritis.

This affection of the growing bones is usually painless, non-febrile, and readily influenced by treatment. It is very different with a morbid state which sometimes accompanies it—suppuration into and about the joints adjacent to the bone disease. This complication is accompanied with fever, often runs an acute course, almost like that of an acute specific disease, is attended with much pain and a pseudo-paralytic condition of the affected limbs, and is generally fatal in spite of treatment. It is to this that HEUBNER'S paper is devoted, and two well-marked cases are described. The comparative rarity of suppuration shows that it is not a necessary consequence of the bone disease, although the latter must be regarded as the exciting cause of the formation of pus, since no case unattended by the peculiar affection of the ends of the bone has yet been met with. Of the cause of the predisposition which exists in some cases, and permits the disease of the bone to excite suppuration, little is yet known. It has no relation to the extent of the osseous mischief. In one of HEUBNER'S cases this was comparatively small, and was lessening, together with a syphilitic eruption, under treatment, when the suppuration occurred, and ran a most rapid course. Moreover, a disposition to the formation of pus can scarcely be regarded as a characteristic of syphilitic lesions. It may be that the chief influence is that tendency to suppuration which is so often manifested by all children during the first few months of extra-uterine life. SENATOR has lately called attention to the great frequency of purulent pleurisy and pericarditis in infants at the breast, and HEUBNER points out also that primary purulent meningitis is almost confined to this age. Moreover, purulent joint affections have been met with in infants as complications of other diseases, such as purulent inflammation of the pleura. This tendency, then, may constitute the predisposition; but although it explains the occurrence of the suppuration, it scarcely explains its rarity. Some additional general or local condition must exist when it supervenes, and this, it is suggested, may be the conveyance of irritating material by the lymph channels from the diseased bone. It is well known that in bone slight influences, scarcely recognisable, may determine the benign or malignant character of an inflammatory process, as in the development of osteo-myelitis. Indeed, the joint affection we are now considering bears resemblance in many particulars to a pyæmic process, and is attended with a similar jaundice.

Its practical importance is very great. It has apparently been almost invariably fatal, and its nature during life has rarely been recognised. Its symptoms—high fever, severe pain, and immobility of limb, with swelling of joints supervening on a slighter affection of the ends of the bones in a subject of inherited syphilis—are so characteristic that the nature of the malady need never be mistaken.

◆

THE *Evening Standard* is dreadfully irate in its own decorous fashion because, in a recent notice of the association for providing nurses for the sick poor, while expressing unbounded sympathy with the main object of this Society, we avowed a certain degree of doubt with regard to the policy, and some misgivings as to the result, of the proposal "to raise the standard of nursing and to improve the social position of nurses." Our courteous contemporary observes censorially: "There is a feeling of uneasiness lest raising the standard of nursing should mean raising the standard of revolt against the heaven-born custom of calling in and paying a doctor always and everywhere. There is an almost sacerdotal fear that if the laity get to learning more than to open their mouths and shut their eyes, and take what the doctor sends them, we shall perchance some day find them applying their own sticking-plaster, dressing a burn, or even putting on a bandage." Considerable candour characterises the way in which the argument is put, and it is impossible to avoid recognising the elegance of the remark about "paying the doctor"; but we are not in a complaining spirit, or inclined to be hypercritical as to words. It may be confessed we do view with suspicion and regard with fear the attempt to develop a separate craft of nursing, and to encourage the "laity" in applying their own sticking-plaster, dressing burns, and putting on bandages; and we will tell the *Evening Standard* and all who may be good enough to be interested in our opinions, why. Trained nurses are, perhaps not unnaturally, prone to magnify the quasi-medical knowledge they pick up in the wards of a hospital, and relying on their intelligence and experience, they apply the sticking-plaster to fractured skulls, dress the burns according to their own notions of expediency, with remedies of their own selection or concoction, and put their bandages on still dislocated or unset fractured limbs. Being intelligent women, and therefore, in their own estimation at least, more gifted than men, they assume, or claim to have acquired, a "practical" knowledge of the art of healing in the course of a brief training under a "sister" not less incompetent than themselves, which qualifies them to act *with* instead of *under* the physician or surgeon in charge of a case, and by their presumption jeopardise the success of his treatment, or even induce the friends of the sick person to dispense with his services. Besides this, the professional recognition given to these women fosters a feeling in the public mind that medicine and surgery are, after all, very simple methods or practices in aid of recovery, and that a "knowledge" which can be acquired in a few months cannot be really very important.

The "trained nurse" tends to displace the doctor, and the intuitive instinct of "common sense" prevalent among the community will in its turn supersede the "trained nurse." The whole movement is essentially retrograde. Medicine has with difficulty succeeded in raising itself to the level of a scientific calling, and now by the creation of a class of professional nurses, it is preparing the way for a return to the days of the "wise women," and further back to that older time, when a false sentiment of religion claimed the art of healing as a mysterious attribute of the priests and their agents, and obviated the need of a laborious investigation of the laws of Nature by an affectation of skill to treat disease by the light and aid of the supernatural. When once the trained nurse is raised above the level of an agent charged to carry out the instructions of the medical man in attendance on a case, she quickly begins to *help* the doctor, and will in the end replace him. We are content to take our contemporary's own account of the use to which the knowledge assumed to be acquired by these nurses is destined. "Take the not uncommon cases of paralysis of the lower limbs, or spinal curvature, with bed-sores. Is it a movement to be viewed with suspicion, that a doctor having such a case under him should have it attended every day for him, and the necessary work done by a nurse who has had the benefit of training?" &c. It is curious that the illustration selected should be one of bed-sores accompanying some cerebro-spinal affection! Has our contemporary forgotten one or two of the more prominent incidents of the recent struggle at Guy's Hospital? Did it not occur to his recollection how in one case want of power, the effect of disease, was mistaken for sulkiness or hypochondriasis; while in another, the "nursing department" in its wisdom routed up a patient suffering from an acute brain affection, and who ought on no account to have been moved, in order to apply a routine dressing of dusting-powder for imaginary bed-sores? Had the nurses in these instances not been "trained," the physicians in attendance might, indeed, have been put to the trouble of giving explicit directions as to their management, and, in order to attain the knowledge requisite to enable them to give these directions, they must, as young men, have mastered the art of *nursing* the sick in practice as well as principle; but all this pain and labour would have been amply compensated by the assurance that the sick under their care were skilfully attended. There is nothing to be gained by "training" nurses beyond the point of making them docile and intelligent attendants on the sick, qualified to carry out the instructions of a medical practitioner efficiently—but *not* qualified to undertake even the *nursing* without his express orders, still less to usurp his position at the bedside, and treat the case.

It is time the profession and the public took the question of training for nurses into very serious consideration. We concede that it is a trouble-saving expedient, but for the sake of ease at the moment we are sowing the seeds of greater trouble in the future. No question can arise as to the need and benevolence of providing nurses for the rich and the poor, particularly the latter; but the nurses so provided should be *nurses* simply and exclusively, not pseudo-practitioners. The practical difficulty arises from the fact that women are naturally of an aspiring nature, and they have for some time past been incited by unscrupulous agitators to struggle for what they are pleased to consider enfranchisement—an enfranchisement from all that is feminine and womanly. They are no longer content to achieve excellence in the *manner* of nursing. The aim—most shortsightedly encouraged by the profession—is to make nursing something more than sick-tending. The "trained nurse" of the day scorns the simple notion of keeping a patient "clean and comfortable," and doing what the doctor tells her in regard to the administration of food and medicine. She must have room to "exercise her discretion," and unless the discretion left is wide, and the "order" given expresses or implies recognition of her special character as the professor of an art of "nursing" which is something beyond the ken of the medical practitioner, she will either "retire from the case"—that is the phrase,—or with mute malignity take it into her own hands behind the back of the doctor and treat it after her fashion. These nurses will do anything to exalt their position and magnify their importance. It every now and again comes to the knowledge of medical practitioners that, having established a reign of terror or blandishments over the patient, they will adopt measures of treatment and even give medicines in secret. As we write, a case recurs to our recollection in which it was discovered that a skilled nurse had been systematically dosing a lady after her confinement with chamomile-tea to such an extent as to prevent her taking proper nourishment. There was no question as to the *bona fides* of this nurse. She meant excellently well, and was treating the case to the best of her "skill" for a symptom which she preferred to keep from the knowledge of the doctor. Neither the patient nor her immediate friends dared to complain, or to breathe a misgiving, to the medical man in attendance until the condition became serious. This was a small matter, and we mention it because it may be thought comparatively insignificant. It is against the small beginnings of insubordination we need to contend. If any association can or will take the trouble to convince the medical profession that its *sole* aim is to train nurses to carry out the instructions of practitioners, the movement will inspire confidence, and deserve our warm support. Nurses should be trained as cooks and housemaids are trained, not to order the dinners or to arrange the domestic business of the household, but to do as they are bidden. If women of "superior intelligence" and "social position" are willing to engage in work of this class—which, however, seems to the last degree unlikely—they may do it as well as those who are less favoured in the matters of birth and education, but there is no reason to suppose they can discharge the onerous and essentially disagreeable duties of the sick chamber more efficiently than respectable women of the classes immediately below them. There is not less need of a new opening for honest work available for the daughters of the artisan class and small shopkeepers, than for the daughters of medical men, clergymen, and the seemingly well-to-do but really struggling classes midway in the ranks of society. We must confess to a strong persuasion that it is from the lower middle classes and the families of the industrial orders of the community nurses should be taken. And being derived from these classes the young women should be trained not to act as *professional* persons in hospitals and private houses, with a profound contempt for menial work, and a proud assumption of the right to be "waited on" and "obeyed" by all about them, but simply to deport themselves and do their duty as tenders-of-the-sick, having the intelligence suited to their position, and showing their skill in the strict and simple performance of the tasks specifically entrusted to them, without either claiming to possess or pretending to exercise a knowledge of disease and its treatment, which must always in fact, and should therefore also avowedly, lie beyond them. It is in the interests of the sick, not less than of the professors of the art of healing, we give expression to these views on the subject of trained nurses, and we are convinced that sooner or later the public and the profession will see cause to agree with us.

◆

LONDON is not only the largest and the healthiest of the large cities of the world, but it is, probably, the only city which possesses trustworthy mortality statistics extending over a period of forty years. The Registrar-General has just issued his Annual Summary of the Vital Statistics of London and other large English cities for the year 1880, completing the fourth decade of observation since the Registrar-General's Weekly Return was first published. The death-rate in London during 1880 is reported to have been equal to 22·2 per 1000 of its inhabitants; and we are told that in only five other of the last forty years has so low a death-rate been recorded. It must be remembered, moreover, that when this Annual Summary was under preparation the results of the recent Census were not known, and that the population of London in the middle of 1880 was, therefore, under-estimated. We now know that the true London death-rate during last year did not exceed 21·5 per 1000, a lower death-rate than which has been recorded in only three of the past forty years. The fatality of zymotic diseases somewhat exceeded the average last year, which was mainly due to the epidemic prevalence of summer diarrhœa; the deaths referred to fever (including typhus, enteric, and simple) showed, however, a further considerable decline, and were fewer than in any year on record. The 475 fatal cases of small-pox showed an increase of 25 upon the number in the previous year, and exceeded the average for non-epidemic years.

The main interest of the present return, however, centres in the retrospect it affords of the health statistics of the forty years 1841–80. The decade which closed with the year 1880 was one of lower mortality in London than any of the three preceding decennial periods for which trustworthy statistics are available. It appears that the death-rate, which had ranged from 23·7 to 24·9 in the three decades of the thirty years 1841–70, and which averaged 24·3 during the whole period, declined to 22·8 in the ten years ending 1880. The rate in the most recent decade, moreover, is further reduced to 22·4, if the mean population of the period be calculated in accordance with the number recently enumerated. The health of London, which was practically stationary during the thirty years ending 1870, showed a marked improvement during the following ten years, and it may be estimated that, at least, 70,000 persons within Registration London were living at the end of the ten years who would have died had the mean death-rate of the preceding thirty years been maintained. It is satisfactory to note, moreover, that if the last decade be divided into two quinquenniads the death-rate in the later is considerably lower than that in the earlier five years. These facts are referred to by the Registrar-General as affording strong evidence that the sanitary efforts of recent years have not been unfruitful, more especially as the increasing density of the population in London would inevitably have led to increased mortality if not counteracted by improved health organisation. The reference of the lower death-rate of the last decennium to improved sanitation in the metropolis appears the more fully justified when it is borne in mind that the saving of life is almost entirely due to diminished mortality from zymotic diseases. It is shown that this mortality, which had been all but stationary during the three preceding decennia, fell during the last decade no less than 25 per cent. below its previous average. A considerable portion of this gain was doubtless due to the immunity from fatal Asiatic cholera during the ten years; but the decline of fever fatality affords undoubted evidence of improved sanitary condition. The average annual death-rate from fever differed but slightly in the first three decades of the past forty years, and averaged 0·92 per 1000. In the ten years 1871–80 this fever death-rate dropped to 0·37 per 1000. We are reminded that these figures signify that nearly 19,000 more persons would have died from fever during the ten years in London if the rate from this cause had remained at its previous level; and further, that more than 100,000 Londoners were preserved from attacks of fever by the improved health condition of the metropolis. The fatality of scarlet fever during the past ten years was also considerably below that recorded in any of the three preceding decades. The death-rates from measles, whooping-cough, and diarrhœa were also somewhat lower during the last decade, although the decline was less marked. Perhaps the most unsatisfactory feature of the recent mortality statistics of London is the slight decline that has taken place in the rate of infant mortality. Infant mortality, measured by the proportion of deaths under one year to births registered, was equal to 158 per 1000 in London during last year, and corresponded with the mean rate in the ten years 1871–80; in the preceding thirty years infant mortality, measured in this manner, averaged 159 per 1000. Bearing in mind the considerable decline in the general death-rate and the marked decrease of zymotic fatality, a larger fall in the rate of infant mortality should have been recorded. Although infant mortality is probably fully as much a social as a sanitary question, it is a subject demanding more attention at the hands of sanitary authorities than it has hitherto received.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL MEDICAL CONGRESS.

THE preparations for the forthcoming meeting of the International Medical Congress are well in hand, and would appear to be worthy of the occasion, which promises to be one of very great interest. The final arrangements for the places of meeting are made, and all the Sections—sixteen in number—will be accommodated in the rooms of the University of London, or of the various Royal Societies close by. The Royal College of Physicians has given up rooms for the offices of the Reception Committee, and this will form the lay head centre of the Congress. The list of members of the Congress is opened already, and those intending to join are requested to enrol themselves at the College of Physicians without delay. At the last there is sure to be a great rush of foreigners, and for this reason, and also to enable the Committee to have a good idea of the number likely to be present, it is desirable that all who can should join at once. We would remind those who have subscribed to the expenses of the Congress that such subscriptions do not include the entrance fee of one guinea. This is charged to everyone, subscriber or non-subscriber, and will hardly cover the bare cost of the literary material presented to each member. We may add that this will consist of a volume, published before the meeting, containing an abstract, in English, French, and German, of all the papers presented to the Congress, and, later on, the volume of Transactions, with all the papers in full. The expense of publishing these volumes will be so great that the fees of membership are hardly expected to meet it. The list of subscriptions is still open, and as there are yet some members of the profession who have not responded to the appeal of the Executive Committee, we would remind them of the adage, *Bis dat qui cito dat.* One of the features of the meeting will be a Museum of Pathology; for this all objects of medical or surgical novelty relating to pathology or the illustration of disease will be acceptable. But the Committee has wisely decided to keep two or three special points in view. One is to show groups of patients illustrating the following rare diseases: Addison's Disease, Coincidence of Gout and Rheumatic Arthritis, Charcot's Joint Disease, Myxœdema, Syphilitic Bone Disease in Children, Mollities Ossium, Primary Muscular Atrophy, Rupture of Large Nerve-trunks, Morphœa, Keloid of Alibert, True Leprosy, Lupus Erythematosus, and Xanthelasma. Dr. Ord has promised to exhibit a series of cases of Myxœdema, and Dr. Dyce Duckworth one illustrating the various phenomena of Gout. It is needless to enlarge upon the instructive nature of a collection of Leprosy cases—say six or ten—such as no one individual could possibly see together without a journey to Norway or India. It is hoped that by the assistance of the various metropolitan hospitals this part of the undertaking will be made very successful. The Committee is anxious that all who have now under their observation cases of the kind asked for will keep the addresses of them, and make arrangements in good time for their attendance. Another feature of the Museum will be a classified collection of drawings, photographs, or models of diseased conditions. It is also proposed to exhibit a collection of Vesical Calculi of unusual character, or those which have been removed by unusual methods, more especially by Bigelow's operation; and of Biliary Calculi of large size which have been passed per anum or removed by operation. Intending contributors to the Museum should signify their intention as early as possible to the Sectional Secretary, Mr. H. H. Clutton, 16, Palace-road, S.E.

THE EFFECT OF PERIPHERAL IRRITATION ON ANÆSTHESIA.

THE interesting observations of M. Grasset on the removal of anæsthesia of cerebral origin by the application of blisters to the skin, to which we directed the attention of our readers in a former number, demonstrate in a striking manner the influence which peripheral impressions exercise on the action of the central nerve-cells. That a similar influence may be produced when the cause of the anæsthesia is not central but peripheral, is shown by an interesting case lately brought before the Société de Biologie of Paris by M. Malécot. There was anæsthesia of the shoulder, arm, and upper part of the forearm following a wound two centimetres long, three fingers'-breadth below the outer extremity of the clavicle, and a finger's-breadth within the anterior axillary line. The resulting anæsthesia involved the shoulder, arm, upper part of the forearm, and the front of the thorax on the same side, being bounded by an irregular line, not corresponding to the distribution of any nerve. There was also some muscular weakness in the forearm. The wound healed, but the anæsthesia remained for two months unmodified by any treatment. The anæsthesia being regarded as reflex, the result of an action on the centre, a blister, ten centimetres square, was applied over the cicatrix. Next day the sensibility had returned in the forearm and inner part of the arm, just above the elbow. A second blister, just above the wound, increased the area of sensibility, and after a third blister the anæsthesia of the shoulder and thorax gradually disappeared.

THE COLLEGE ELECTIONS.

MONDAY next is the last day for sending in applications for election into the Council of the Royal College of Surgeons. The Fellows who may be expected to compete are Sir James Paget, Mr. Haynes Walton, Mr. Sydney Jones, Mr. Hulke, Mr. Croft, Mr. C. Heath, and Mr. Reginald Harrison.

EMPLOYMENT FOR SOLDIERS' WIVES.

IT is satisfactory to know that those with whom rests the responsibility of the nursing in military hospitals are by no means so blind to the difficulties involved in Lady Strangford's scheme for the employment of soldiers' wives in that duty as the report of the proceedings of the meeting at Woolwich fairly seemed to indicate (see THE LANCET of June 4th). It appears from a statement in the *Broad Arrow*, that the report of that meeting which was furnished to the daily papers was very inaccurate, one-sided, and incomplete. While it recorded the presence of Lord Chelmsford, Sir Frederick Roberts, and Lady Strangford, it omitted all reference to Surg.-General Shelton, who might be naturally supposed to have more practical knowledge of the subject than most of those who took part in the proceedings. But he did not, like Lord Chelmsford, endorse all the views held by the lady patroness; on the contrary, he pointed out the practical objections to the scheme, and foreshadowed the difficulties likely to arise in working it, and on that account, we presume, his presence at the meeting was ignored, and his remarks were not reported. The point to which Mr. Shelton chiefly called attention was the existence already of agencies for nursing in the army. These are—(1) The Army Hospital Corps, which has shown itself so efficient on service in the Transvaal; (2) the regular staff of trained female nurses at Netley and Woolwich, always available for service when they may be required; (3) the staff of female nurses supplied by the National Aid Society, and now undergoing training in the military hospitals; and (4) the female nurses specially employed wherever there is a hospital for women and children. With these resources in existence, Mr. Shelton doubted the expediency of starting another organisation which could only be carried on efficiently at a very considerable outlay. Is such a course necessary, and is it justifiable? We are disposed to answer these questions in the negative. It seems much more desirable to improve, and if necessary to extend, systems now in operation, and which are doing really valuable though unostentatious work, than to start new societies with the usual staff of paid officials, and with the drawback of coming into unnecessary competition with those already in existence. The omission from the report of the Woolwich meeting of any reference to Surgeon-General Shelton—the representative of the Army Medical Department—to the telling remarks made by him on the unnecessary expenditure of labour and money likely to arise from carrying out the scheme, and to the clear exposition he gave of the adequate provision already in operation for nursing in military hospitals, has given rise to an unpleasant feeling with reference to a movement which, if necessary, ought to enlist the warmest sympathies of all who feel an interest in the welfare of our soldiers.

ST. GEORGE'S HOSPITAL AND THE ATKINSON-MORLEY CONVALESCENT HOSPITAL.

THE annual report of St. George's for this year is an interesting one, though we can only note a few of the principal facts. As to out-patients, means have been taken to reduce the number, so that relief should be given only to the necessitous. The decrease in 1880, as compared with 1879, is 142. We are struck by the smallness of this number. As regards in-patients, the most noticeable fact is that 2500 out of 3543 were admitted without letters of recommendation, and in consideration only of the urgency of their cases. The Hospital Saturday Fund withheld £100 on account of not receiving more letters, though it received in the same proportion as the Hospital Sunday Fund, and 52 more than it used. The hospital makes out so good a case that the Hospital Saturday Fund should send the £100, especially as the managers of the institution, in consequence of decrease in receipts and increase in expenditure, have had to sell nearly £8000 worth of stock. In the letter of the secretary to the secretary of the Hospital Saturday Fund, it is said that of the number treated in the hospital, 1500 were working men or their wives and children. We are curious to know the occupation of the remaining 2000, which, the secretary would seem to imply, were *not* of the working class. Of the 3180 patients discharged from the hospital in 1880, 681, or 21·35 per cent., were admitted to the Atkinson-Morley Convalescent Hospital.

FISH.

THERE can be no question that fish might with advantage form a more common article of diet than it now does. It is notorious that the market supply is manipulated to keep up prices, the commodity being regarded as a luxury rather than a necessary. Nobody is to blame for treating the article thus *commercially*, but it is a reproach to the good sense of the community that the value of fish as an article of food is not generally recognised. It is eminently a form of nutriment well suited for the use of a population working to a very considerable extent with its brains, and exposed in no ordinary degree to the wear and tear caused by worry. If proper arrangements were made for the rapid transit of fish to the metropolis, and an adequate and accessible market were provided for its sale, the population might be well supplied at reasonably low prices. Obviously those who trade in fish cannot be expected to incur the risk of loss by the spoiling of a peculiarly perishable article before it can be distributed, and they may well be excused for some finessing to keep up prices; but difficulties such as these ought to be overcome. It is not necessary to point out to medical readers the importance of a full and good supply of fish, but it is time the profession took means to bring considerations well known to themselves under the notice of the public, so that the opportunity which seems to have occurred for the removal of needless obstacles to the use of fish as an element of ordinary diet may be utilised.

ANOTHER HOSPITAL DIFFICULTY.

WE understand that a serious difference of opinion exists at the Bristol General Hospital between the Staff of the institution and the Committee (or rather a small majority of the Committee) as regards the material best suited for use in the reflooring of the wards. It appears that when the hospital was rebuilt in 1856, cement floors were laid down, and that in the brief period of twenty years these floors had become so bad that it was necessary to renew them. The Staff held strongly that cement was not suitable for the flooring of a hospital, and that wood was the only material that should be used; the Committee, however, in the face of this, by a bare majority, decided to relay cement; and accordingly this material was used throughout the building. Within a few months the condition of these new floors had become so faulty that the Committee were warned by the Staff of the danger that might arise to the patients under treatment in the institution. Various experiments were tried in the attempt to put the existing floors into a satisfactory condition, but without success; and the latest decision of the Committee has been to entirely relay one of the wards with cement—the very material that had already so signally failed—turning a deaf ear to the emphatic and repeated protests of the Staff, and to all the scientific evidence that has been furnished them in proof of the great superiority of wood. The matter has assumed so serious an aspect that the president of the hospital has resigned his post, on the ground that he cannot share the grave responsibility thus incurred by the Committee; and we believe that the Staff are taking measures to bring the whole case before the general body of governors of the institution. It is difficult to conceive how a body of men possessed of average intelligence and capable of forming an unbiased opinion, could have taken so erroneous a course as that adopted by the Committee. The cement floors had signally failed; surely if the same material was worthy of any further trial, it should possess advantages from a medical point of view far greater than any other. But exactly the reverse is the fact. In the first place cement is highly absorbent, and is therefore calculated to form a fit soil for the development of those preventable diseases—erysipelas and the various forms of blood-poisoning—against which it is the aim of modern science to defend a hospital. Further—and this, too, is a very grave objection—a cement floor is exceedingly cold, and cannot but exercise a most injurious influence upon many patients. It is well known that even persons in apparent health will suffer from rheumatic pains after standing on stone or cement floors; and upon patients whose vitality is lowered by disease the chilling effects of such floors will in many cases exercise a most prejudicial influence. Wood is unquestionably the only material fit for hospital floors. It can be so laid and coated as to be non-absorbent, it is easily cleaned and kept in good condition, it is far less noisy than cement, and is warm and comfortable for the patients—in short, it is in every respect incomparably superior to cement. The latter material is suitable for barns and warehouses, but is altogether out of place in a hospital. We cannot but think that those members of the Committee who are so anxious to perpetuate the mistake originally made in the hospital would hardly select cement as a flooring for their own bedrooms. It appears that, according to the existing rules, the Staff send two representatives to the Committee, but that these have no power to vote. The position in which men of scientific training and high professional standing are thus placed is most anomalous; and recent events have shown how important it is that those who are best qualified to decide the scientific questions that from time to time come before a hospital committee should be able to enforce their opinion by a vote. We believe our view will be endorsed by the governors of the hospital when the matter comes before them for consideration.

INOCULATION OF RABIES.

M. PASTEUR and his assistants have succeeded in communicating rabies by the inoculation of the brain of a dog dead of the disease. The experiments were successful with pieces of the cortex and of the medulla oblongata, and with the cerebro-spinal fluid. There is, of course, nothing very remarkable in this result. It has long been known that the virus is widely diffused in the body of the dog, and it would be strange if the brain did not contain it, when we consider the demonstration which the symptoms afford of the action of the poison on the nerve-centres. M. Pasteur moreover asserts that by trephining a healthy dog, and placing in contact with its brain cerebral tissue from a rabid animal, not only is the disease communicated with certainty, but the incubative period is reduced to a few days in every case. The disease may manifest itself in either of its two habitual forms—the ordinary form, or "dumb-madness."

BANQUET TO THE PRESIDENTS OF THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.

ON Saturday, the 4th instant, Sir William Jenner and Mr. Erichsen were entertained at a banquet at St. James's Hall, given in their honour by their colleagues in the Faculty of Medicine of University College and on the staff of University College Hospital. The chair was occupied by Professor John Marshall, F.R.S., who was supported on his right and left by the two guests of the evening. In addition to members of the present staff, there were present Dr. Russell Reynolds, Sir Henry Thompson, Dr. Hare, Dr. George Harley, and Dr. Maudsley. Dr. Walshe and Mr. Quain were unavoidably prevented from attending. The meeting was purposely made as informal and as friendly as possible, and the only toast was that of the two distinguished guests, who, having been fellow-students together and colleagues both at the college and hospital, had respectively risen to the highest attainable distinction in their respective branches of the profession. It was pointed out by the chairman that, although it is necessarily a somewhat rare event for the Presidents of the two Colleges to be supplied from the same medical school, it is by no means without precedent. The dinner was excellent, and the evening will long be remembered as a pleasant social gathering of friends to do honour to colleagues of whom they may well be proud.

SUICIDE WITH A REVOLVER.

A VERY remarkable case of suicide occurred at the village of Priors Marston, near Leamington, on May 15th. The deceased, a master bricklayer, aged fifty-nine, was found by his brother-in-law, dead, lying on his right side near a chest of drawers, and with his clothes on fire. This was at 12.20 P.M. on Sunday, May 15th. Mr. F. W. S. Culhane deposed that on stripping the body he found the skin under the left nipple blackened and charred, and in the centre of it a wound, which had the appearance of a bullet wound, and was found to traverse the pericardium and both ventricles of the heart. The sixth rib was broken, and the pericardium full of blood. The bullet was not found. The body when first seen was quite warm. The charring and burning of the chest were due to the clothes being on fire. The burns had the character of post-mortem burns. When first found the heels of deceased were almost touching the chest of drawers. The top drawer was partially open, and in it was found a seven-barreled revolver with one chamber recently discharged and the other six loaded. The case presents several points of interest. In the first place the burning and charring were so considerable (the coarse jacket, corduroy waistcoat, shirt, under-vest, and band of trousers being destroyed almost entirely on the left side) as to lead to the idea that death was in some way connected with burning, and it was only on a close examination that the bullet wound was discovered in the middle of the charred wound. The dropping of the pistol into the drawer in which it was found was a very peculiar circumstance, and the accidental closing of the drawer by the first person who came into the house made he cause of death still more of a puzzle at first sight. However, there was no doubt that it was a self-inflicted wound, and the only question lay between ccident and suicide.

ROYAL COLLEGE OF PHYSICIANS.

A MEETING of the Royal College of Physicians was held on the 8th inst., under the presidency of Sir William Jenner, Bart. A letter from the Secretary to the Medical Acts Commission inviting the College to specify any matters within the scope of the Commission upon which the College could afford further information was under consideration; but no conclusion was arrived at. After some discussion it was decided to summon a special meeting at an early date for the purpose of obtaining a definite expression of opinion on the part of the College as to the way in which its interests would be affected in the event of a State Licensing Board being instituted; and also to give the Commission such information as might be deemed necessary upon the whole subject.

M. LITTRÉ.

BY the death of M. Littré the medical profession loses one of its most distinguished members. Though M. Littré was not a medical man in the strictest sense of the term, he devoted ten years of his earlier life to the study of medicine and the allied sciences. He was finally prevented from taking his degrees by the loss of his father, which compelled him to lay aside for awhile his intention of practising physic to take to literature. Next to his famous dictionary of the French language his best known work is his edition of the Hippocratic treatises. To the preparation and publication of this work he devoted more than twenty years of painstaking labour. Littré's "Hippocrates" is, and will probably remain for many years to come, the most complete and scholarly collection of the treatises written by the "father of medicine" and his disciples. M. Littré was a conspicuous illustration of the healthfulness of hard work. His industry was as inexhaustible as his learning, and though over eighty years of age his energy until a few months ago showed but little abatement.

ARMY MEDICAL OFFICERS' BENEVOLENT SOCIETY.

AT the annual meeting of the Army Medical Officers' Benevolent Society, held on May 21st, Inspector-General Lawson in the chair, £770 were voted, in various sums ranging between £10 and £50, to thirty-one orphan families of medical officers, with the object of assisting in their education. This Society, which was founded in 1820 by the late Sir James McGrigor, Bart., for so many years the Director-General of the Army Medical Department, has during the long period of sixty years been the means of affording valuable and much-needed assistance to the orphans of medical officers. Very careful inquiries are made into the circumstances of all candidates before any recommendations are made by the committee, and we have reason to believe that the affairs of the Society are efficiently and prudently conducted, and that it well deserves the countenance and support of the Department.

CHURCH BELLS.

THERE is not a word to be said against church bells in the abstract, or in their proper place—that is to say, in the country, where a peal of bells may be useful to call the residents scattered over an extensive district to service; but in towns they are an intolerable and most mischief-working nuisance. To the sick, suffering from headache and nervous irritation, the ding-dong and jangle of church bells constitute a very serious annoyance; and we do not hesitate to say, in many cases, the loss of rest and the general disquietude they produce not only lessen the chance of recovery, but may expedite a fatal issue. This is a grave charge, but we make it advisedly. The labour of covering the roadway with tan or straw, to drown the noise of passing vehicles, is vain while the bells of the neighbouring churches remain unmuffled. It is difficult to exaggerate the magnitude of the evil to which we draw attention. It is a daily cause of injurious excitement to the sick, and a provocative of ill-temper to the healthy. The time is approaching when it may be needful, in the interests of the weak and suffering, to apply to the Legislature for a special enactment prohibiting the ringing or tolling of church bells in populous localities. For the present, however, the appeal lies to the humanity of the clergymen and churchwardens of city and suburban parishes. Surely they will not persist in a perfectly unnecessary infliction, which is shown and known to work dire evil!

"HOMŒOPATHIC REMEDIES" DO NOT ACT HOMŒOPATHICALLY.

THE medical profession and the public will be interested to learn, on the highest authority, that homœopathists do not themselves believe that what are called "homœopathic remedies" act *homœopathically*. It seems that no homœopathist has of late years even pretended that the drugs he employs cure disease on the principle *similia similibus curantur!* This dogma is simply a statement of the so-called "principle" on which the homœopathist selects his remedies. This is obviously a minor consideration, and one in which the public has little if any interest. What the patients of homœopathic practitioners expect from these gentlemen, and fee them for, is "homœopathic *treatment.*" It is a matter of perfect indifference to the sick man or his friends how the physician *selects* his drugs. The only practical question is how he treats his cases, and in what manner the drugs act. Having elicited a frank confession of the facts as to the action of drugs, we can only appeal to honest men still connected with this so-called "Homœopathic School" to abandon openly a position which they admit does not exist, and which is, therefore, only a name—full of meaning to the lay public, but of no significance to themselves. We do not wish to speak strongly on the subject, but it is certainly the reverse of candid to retain a name which means nothing and deludes the public. With the publication of the letters which appear in another column, the discussion must end. The truth is now at length before our readers on the admission of leading homœopathists, and the only possible inferences are writ large and plain.

THE INFLUENCE OF THE VAGUS ON THE HEART.

M. FRANÇOIS FRANCK has endeavoured to determine on what part of the heart the influence of the vagus is first manifested. He has found that if the peripheral extremity of the divided pneumogastric is stimulated with a current so feeble as to just produce the arrest of the cardiac action, the ventricles alone cease to contract; the auricles on the contrary go on pulsating, but more slowly than before, and if the stimulation is continued or is increased, they also stop. It is supposed that, normally, the systole of the auricles is the immediate excitant of the systole of the ventricles, but the stimulation of the pneumogastric in this case appears to prevent this normal response to the auricular contraction, although the effect of the latter in distending the auricle continues, as a manometer introduced into the ventricle demonstrates. This is true, however, only of the right side of the heart. When the ventricles are arrested the left auricle receives little or no blood, while the right auricle becomes distinctly overfilled. The difference is probably due to the slight tonicity of the pulmonary vessels compared with those of the general system. It is not owing to any simultaneous contraction of the vessels of the lungs, due to the stimulation of the vagus, for, as Brown-Séquard and others have shown, the vaso-motor nerves of the lungs are derived from the sympathetic, and not, as has been taught, from the pneumogastric nerve.

BILLROTH'S CASE OF EXCISION OF THE PYLORUS.

WE learn from the *Wiener Medicin. Blätter* that the woman upon whom Professor Billroth performed the operation of excision of the pylorus and adjacent part of the stomach, with temporary success, for the cure of a cancerous growth, has just succumbed. The operation was performed in January, and all promised well until about a month ago, when she began to fail, and death took place from exhaustion. She has lived long enough, however, to testify to the practicability of the operation.

PROVIDENCE IN MANCHESTER.

THE forty-ninth annual meeting of the subscribers to the Manchester and Salford District Provident Society was lately held. The committee seems to have been able to give a good account of its stewardship. Reference was made to the Provident Dispensary Association thus:

> "The establishment of provident dispensaries was contemplated in the original scheme of the Society, and the amalgamation was welcomed by the Provident Dispensaries Association, whose organisation for want of sufficient funds was at the time only making slow progress towards providing efficient medical aid and medicine, at low weekly subscriptions, for the families of working men who, not able to pay ordinary medical fees, were either left to neglect, plunged into debt, or were reduced to beg for charitable aid. The experience of the past year had taught the Committee that the task they had undertaken would be no easy one, and that they must expect little aid or sympathy from existing medical associations. It was thought that the expenditure—spread over three years—of £2500 would be sufficient to meet the requirements of the Society for that purpose, but the Committee now believed they would require at least £4000 to thoroughly establish and accomplish the work they desired to do."

MUMPS.

MM. CAPITAN and CHARRIN, having regard to the clinical evidence on which mumps is classed among the acute infective diseases, have searched for an organised virus in the secretions of patients suffering from the disease. In the blood of every case they found an abundance of minute organisms, for the most part spherical, but partly prolonged, and in the form of mobile rods. In the saliva, as is usual, there were large numbers of organisms, but most of these resembled those found in the blood. None could be discovered in the urine.

WE learn that Dr. Pavy has been pursuing his investigations upon the physiology of sugar and its allied principles in the animal system, and has obtained results which have opened out a fresh line of research, and led up to a new light being thrown upon the subject. His results will be brought before the Royal Society at the last meeting of the session on Thursday next.

DR. BARCLAY of London, Dr. A. Ransome of Manchester, Dr. De Chaumont of Netley, and Dr. Corfield of London, have been appointed examiners for the sanitary science certificate at Cambridge. The examination will commence on Oct. 4th. Professor Liveing is the secretary.

A MEETING for the purpose of discussing the project of establishing a Scarlet Fever Convalescent Home is announced to be held at the Mansion House on the 27th inst., at 3 P.M.

IN Edinburgh the winter months are now so largely occupied by systematic lectures that students are anxious to overtake most of their practical work during the summer session, and this accounts for the increase in the number of short courses on special subjects which are undertaken at this time. These lectures are mainly voluntary as regards attendance, and yet they are in many cases crowded—as, for instance, the class of Practical Physiology in the University. The Histological and Practical courses on Pathology in the University and extra-mural schools are also well attended, while in the dissecting-rooms students in unusually large number are at work. The new class-room in the Botanical Gardens is now in use.

WE direct the attention of our readers to important notices with reference to medical registration. Gentlemen are occasionally astonished to find themselves no longer on the Medical Register. The explanation is that they have changed their address without giving notice to the Registrar. Under these circumstances the Council is empowered to remove names. It is important to notice that it is not enough to intimate change of address to any Registrar. The intimation must be made to the Branch Registrar by whom the practitioner was originally registered.

A SPECIAL hospital has been opened at St. Petersburg for the treatment of epileptics and idiots—classes of patients excluded both by the existing general hospitals and the lunatic asylums. The hospital is situated out of the city, on the line of the Finland railway, in a healthy position amidst gardens and pine forest, and is furnished with great comfort. Dr. Thiling, who has given special attention to the treatment of mental maladies and diseases of the nervous system, has been placed at the head of the medical staff.

AT a stated meeting of the New York Academy of Medicine, held May 19th, 1881, the following resolution was moved by Dr. Charles C. Lee, seconded by Dr. Alfred C. Post, and unanimously adopted:—"That the congratulations of the New York Academy of Medicine be transmitted to T. Spencer Wells, Esq., Foreign Associate of the Academy, for his remarkable and unprecedented achievement of one thousand operations of ovariotomy, by which the lives of seven hundred and sixty-nine women have been saved."

MR. MCALISTER, who was senior wrangler in 1877 and subsequently pursued medical study at Cambridge and at St. Bartholomew's Hospital, has been appointed medical lecturer in St. John's College, Cambridge. The office is a new one, and its occupation by so distinguished and able a person is likely to attract medical students to the College and to give additional efficiency to the medical school of the University.

WE understand that a conversazione will be held at the South Kensington Museum on Wednesday evening, June 29th, to celebrate the fiftieth anniversary of the Harveian Society. A committee to carry out the arrangements has been appointed, consisting of the President, Mr. Henry Power, Dr. J. E. Pollock, Dr. Farquharson, M.P., Mr. George P. Field, and Mr. Malcolm Morris.

A SORT of Co-operative Workmen's Medical Association has been started at Chatham. About two thousand artisans residing at Rochester and Chatham are said to have joined the Society. They will appoint their own medical officers, purchase their own drugs, &c.

DR. STURGES has been appointed Foreign Examiner in Medicine at the University of Durham for the present year.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Port of London.—The Reports of the Port of London Sanitary Committee and of its medical officer of health for the half year ending the 31st December contain several matters of much interest. They give an account of valuable work done during the period to which they refer, and suggest certain important questions for further consideration. It appears that the number of ships visited during the half year was 8740, including 398 "outward bound," and that of these ships 354 were found in a more or less insanitary condition. The total number of ships visited during 1880 was 16,341, of which 563 had to be cleansed or otherwise dealt with sanitarily. But the diminution in the number of unwholesome ships visiting the port since the Port Sanitary Authority commenced its work is remarkable. In 1873 no less than 17 per cent. of the vessels inspected were found uncleanly; during the six months to which this report refers, only 3 per cent. had to be so classed. Hitherto the detailed sanitary work of the port has had to be done by the medical officer of health, aided by two inspectors. This strength of staff has not been found equal to the demands made upon it by the new arrivals daily, and the visitation of ships in dock has had to be neglected. The Sanitary Committee has now decided to appoint a third inspector. Dr. Collingridge reports the health of the port as having been exceedingly good, with the exception of certain outbreaks of infectious sickness on board the training ships. Sixty cases of sickness were removed from ships to hospital. The state of the water in the river during the summer gave rise to some anxiety from the large quantity of sewage it contained. This was derived in part from the floating population of 15,000 to 20,000 persons, from numerous still open drains and closets which empty into the river, and which will require special attention, and from a proportion of sewage derived, Dr. Collingridge states, from the outfalls of the great metropolitan sewers at Barking and Crossness. Dr. Collingridge evidently is suspicious that the sluices at these outfalls have been at times opened during the flow of the tides. It is clear that the vexed question of the influence of the sewage outflow at Barking and Crossness upon the state of the water in the river above the outfalls is not yet fully settled, the Metropolitan Board of Works notwithstanding. But readers of the report will probably be more interested in the suggestion made by Dr. Collingridge that a further epidemic of typhoid fever on board the reformatory school ship *Cornwall*, anchored, if we mistake not, five miles below the metropolitan sewage outfalls, may have been determined by the sewage poured from these into the river and diverted into the bight where the ship rides. He writes of the volume of sewage being visible in the stream where the ship lies, and of chemical evidences of greater sewage pollution of the water on the north shore than the south. "If the constant outpouring of the sewage continues," he writes, "it will become sooner or later a grave question whether the Thames will any longer be a proper or safe river for stationing training-ships." In view of the serious question here suggested, and of other questions not less serious, it is to be hoped that Dr. Collingridge will give continuous attention to the subject. His statement as to visible evidence at Purfleet of the large outflow at Barking and Crossness will strike many persons with surprise; and with regard to the chemical evidence considerable doubts will be entertained. The metropolis is often accused by residents on the lower reaches of the river of "stinking them out" by the offensive refuse it frequently sends down for agricultural purposes in barges. Dr. Collingridge's revelations as to the enormous quantity of fish condemned at Billingsgate indicate in part a source of the intolerable stench to which people inhabiting the rural districts on the Thames below London are subjected. Dr. Collingridge has some observations on the port sanitary authority's hospital-ship, the *Rhin*, which suggest increased doubts as to the wisdom of the selection of a ship for hospital purposes by the Metropolitan Asylums Board, to relieve the pressure upon them in reference to small-pox.

Greenock.—A copy of a correspondence as to landing infected persons from emigrant ships at Greenock accompanies the reports for the month of April of the medical officer of health (Dr. Wallace) and sanitary inspector (Mr. Mackay). From Mr. Mackay's report we learn that emigrants suffering from infectious diseases have been sent ashore and forwarded to Glasgow in the most promiscuous way, without information being conveyed to the sanitary authorities either of Greenock or Glasgow. Now that attention has been called to this matter no doubt the arrangements for the medical inspection of emigrants, which are described as "inherently bad," will be modified.

Hastings.—Mr. Ashenden reports for the first quarter of the year a birth-rate of 30·19 per 1000 of the population, and a death-rate of 16·75. The advantage of the borough possessing a sanitary hospital was shown by the occurrence of two cases of small-pox (a mother and child) who were removed there, and the spread of the contagion arrested.

Birmingham.—Dr. Hill reports for the first quarter of the present year births at the annual rate of 39·59 per 1000 population, and deaths at the annual rate of 21·29 per 1000 population.

Dublin.—Dr. Cameron reports for the five weeks ending 30th April that the mortality of the city was in the annual ratio of 31·78 per 1000 living, the rate being 31·8 on the northern side of the city, and 32·36 on the southern. Typhus predominated among the zymotic diseases.

THE CARDIFF UNION WORKHOUSE.

Dr. Alfred Sheen, the medical officer of the Cardiff Union Workhouse, has issued an excellent report on the medical condition of the workhouse and schools belonging thereto for the year 1880-81. The cases of sickness admitted to the workhouse hospital during the year numbered 1087, of whom 617 were discharged cured, 183 relieved, 16 transmitted to the asylum, and 131 died, 140 remaining under treatment on the 25th March. It is evident that during the period to which the report refers the workhouse has been sorely put about from insufficiency of space to bestow upon its sick, and in respect to accommodation of cases suffering from infectious maladies. But these difficulties, it appears, will presently be remedied, as a new Union workhouse is now being erected which will give double the accommodation afforded by the old one. The question of nursing in the workhouse hospital seems to require attention, for the arrangements do not appear to have been framed with due regard to the number of serious cases of maladies now received in it. The consumption of stimulants in the workhouse, which Dr. Sheen showed in his previous report had been largely reduced, was still further reduced last year. The schools are reported as having been free from any serious amount of disease during the year. We learn that it was the custom until recently to allow children born in the workhouse to leave the house unvaccinated to swell the section of the population unprotected against small-pox. This Dr. Sheen has now remedied, and finds, it would appear, little difficulty in obtaining the mother's consent to the vaccination of the child before she goes forth among the general population. The reference to the fact calls attention to this curious oversight of the Vaccination Authority (the guardians themselves forsooth), and how readily it may be overcome without anyone's feelings being offended as soon as attention is directed to it.

THE METROPOLITAN WATER-SUPPLY.

Colonel Bolton, R.E., reports that the water in the Thames in that part of its course where the Metropolitan Water Companies draw from the river their supplies was good in quality during the whole of April; and Mr. Crookes, Dr. Odling, and Dr. Meymott Tidy report for the month ending May 19th that the waters supplied by the different water companies had been "uniformly clear, bright, and almost colourless, proving that they had been well and efficiently filtered." Examined chemically they showed "excellent aeration and great freedom from organic matter. They leave nothing to be desired for dietetic purposes."

AN IRRECONCILABLE COW.

At the recent Dorset Quarter Sessions, on the discussion of a report from the county analyst, Viscount Portman brought before his colleagues the case of a cow which utterly disregarded the provisions of the Adulteration of Food Acts. The proprietor of the animal had been convicted by the magistrates for selling milk deficient in cream, and had appealed against the decision. After careful examination the Inland Revenue Department Laboratory found that the deficiency arose from no manipulation of the milk, but was peculiar to the cow from which it was obtained. The law has made no provision for a contingency of this sort. The milk was normally abnormal, and we presume that cows so constituted will have to be discarded from contributing to the public milk-supply. Practically, we presume that every milk-farmer should submit the product of his kine to the county analyst before he ventures to send it into the market.

ALDERSHOT AND SMALL-POX.

Those persons who never tire of decrying vaccination might profitably reflect on the immunity enjoyed by the camp at Aldershot. There has not, we have reason to know, been a single case of small-pox at Aldershot, and there can be no doubt in the minds of unprejudiced people that this happy state of matters is due to the excellent arrangements for securing the revaccination of every recruit in the Service. It cannot be doubted that constant intercourse must go on between London and Aldershot; but between vigilance and vaccination the disease has found no footing in the latter place. One soldier lately on furlough was known to have been staying with his mother, who had just died of small-pox. On returning to the camp he was put into quarantine until it was apparent that he was not the bearer of infection.

In view of the persistence of small-pox in London, and mindful of the sufferings which befell their borough ten years ago, the Nottingham Town Council have issued posters and are distributing an excellently prepared pamphlet by their medical officer of health, Dr. Edward Seaton. An attempt has been made to counteract the beneficial effects which the posters and pamphlet are likely to have by a correspondent of one of the local papers throwing doubt upon the policy of revaccination and quoting a series of arguments against *compulsory* revaccination, put forward in a recent discussion before the French Academy of Medicine on the subject. Nothing is said by this correspondent of the arguments to the contrary, although they have resulted in the Academy voting by a large majority for the establishment of both compulsory primary vaccination in France and compulsory revaccination.

The Midland Railway Company have prosecuted at the Bedford Petty Sessions two individuals (brothers) who had travelled by their line to that town while suffering from small-pox. In one case the individual was on his way from London to Leek, but his condition being discovered, he was removed from the train at Bedford and taken to the Small-pox Hospital there. The second case was curious. The individual sickened at a later date than his brother, but failing to obtain admission into a hospital in the metropolis, he deliberately travelled to Bedford in hope of getting admission into the hospital there, in which his brother was then under treatment.

The Lord Chancellor has declined to add to the roll of justices of the peace for the borough of Southampton the name of a gentleman who had been twice convicted and fined for offences against the Vaccination Act, notwithstanding he was sheriff of the town and county. In answer to a question on this subject in the House of Commons, the Home Secretary observed that "a gentleman who had not himself recognised the duty of obeying the law was hardly a suitable person to add to the roll of borough magistrates."

Small-pox, it would appear, has seized hold of Gravesend. Seventeen cases of the disease are under treatment in hospital there, while others are being treated in their own homes. In one instance, it is stated, where a child suffering from the disease was improperly lodged in a house occupied by other families, the magistrates refused to give an order for removal to hospital, and three of these families have since contracted the disease.

The want of an infectious disease hospital for Rochester and Chatham has now, it is reported, been met by the joint action of the Corporation of the former with the Local Board of the latter. The cost of the building is estimated at about £5000.

It is understood that the West Ham Local Board is about to apply for an injunction against the Poplar Board of Works in respect to their Small-pox Hospital in the West Ham district. It is not stated whether West Ham will seek an injunction against its own Small-pox Hospital, which adjoins the Poplar Hospital, or whether it will close it of its own accord, or whether it will use it if necessary.

The Corporation of Huddersfield have successfully prosecuted a householder for not having notified under the Local Act the existence of infectious disease in his family, a medical man not having been called in. This being the first case under the Act a heavy penalty was not pressed for, and the Bench simply inflicted a fine of 1*s.* and the expenses.

Opposition has been withdrawn to the Bill before Parliament authorising a company to construct conduits from Lancing, on the Sussex coast, to London for the supply of sea-water to the metropolis.

It is reported that at the request of the Metropolitan Asylums Board a second ship is to be prepared for the reception of small-pox patients, it having already been found that the *Atlas* will not be equal to the demands upon it.

Professor Ruskin has raised his voice against the pollution of Coniston Lake, and it appears likely that the Ulverston Rural Sanitary Authority will give ear to his remonstrances.

A French lugger recently put into Aberdeen with one of the crew ill from small-pox.

A fatal case of revaccination in a lady over sixty years of age is reported from Sittingbourne.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a slight increase last week. In twenty of the largest English towns, estimated by the Registrar-General to contain in the middle of thi year a population somewhat exceeding seven and a half millions of persons, 5194 births and 2967 deaths were registered last week. The births exceeded by 8, while the deaths were 290 below, the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had been equal to 20·8 and 20·0 in the two preceding weeks, rose again to 20·3 last week. The lowest rates in the twenty towns last week were 12·6 in Brighton, 14·4 in Wolverhampton, 15·3 in Plymouth, 16·9 in Leicester, and 17·0 in Bradford. The rates in the other towns ranged upwards to 22·7 in Sheffield, 23·7 in Sunderland, 23·9 in Bristol, and 25·5 in Manchester. During the first nine weeks of the current quarter the death-rates in the twenty towns averaged 21·1 per 1000, against 23·2, the average rates in the corresponding periods of the five years 1876–80.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 396, 424, and 452 in the three preceding weeks, declined to 446 last week; these included 116 from measles, 91 from whooping-cough, 85 from small-pox, 60 from scarlet fever, 37 from fever (principally enteric), 43 from diarrhœa, and 14 from diphtheria. The annual death-rate from these principal zymotic diseases averaged 3·1 per 1000 in the twenty towns, and ranged from 0·0 and 1·0 in Plymouth and Brighton, to 3·4 in Leicester, 3·7 in London, and 4·0 in Sheffield. Measles showed the largest proportional fatality in Bristol, Sheffield, and Newcastle-upon-Tyne; scarlet fever in Wolverhampton; and whooping-cough in Leicester, Sheffield, Leeds, and Manchester. The 14 deaths referred to diphtheria included 9 in London and 3 in Portsmouth. Enteric fever caused the highest death-rate in Portsmouth, Hull, and Newcastle-upon-Tyne. Small-pox caused 90 more deaths in London and its outer ring of suburban districts, and 1 each in Liverpool, Manchester, and Newcastle-upon-Tyne; no fatal case of this disease was recorded in any of the seventeen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased from 942 to 1552 during the four preceding weeks, further rose to 1644 on Saturday last; of these 583 were accommodated in the Convalescent Camp Hospital at Darenth. The new cases admitted to these hospitals, which had been 346 and 402 in the two previous weeks, were 359 last week. The Highgate Small-pox Hospital contained 86 patients on Saturday last, and 28 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had been 256 and 241 in the two preceding weeks, were 249 last week, and corresponded with the corrected average number in the last ten years; they included 133 from bronchitis and 84 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 3·4 per 1000 in London last week; while the rate from the same diseases was 5·2 in Liverpool and 3·5 in Salford.

The causes of 44, or 1·5 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths in London did not exceed 0·9 per cent., whereas it averaged 2·1 in the nineteen provincial towns. No uncertified deaths were registered last week in Brighton, Portsmouth, Norwich, Wolverhampton, or Nottingham; whereas the proportions of such deaths were largest in Salford and Oldham.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half of persons, the annual death-rate last week was equal to 20·6 per 1000, showing a slight increase upon the low rate that prevailed in the previous week; this rate was 0·3 above the average rate last week in the aggregate of the twenty large English towns. The ratio in these eight Scotch towns ranged last week from 10·6 and 13·7 in Paisley and Dundee, to 26·0 and 27·3 in Leith and Perth. The Registrar-General of Scotland again notes that he has not yet revised his estimates of population in accordance with the numbers recently enumerated; it is pointed out, however, that the rates in some of the towns, especially in Paisley, are probably over-stated through an under-estimate of their present population. The deaths referred to the principal zymotic diseases in the eight towns, which had been 61 and 72 in the two preceding weeks, declined again to 62 last week; they included 14 from whooping-cough, 14 from diarrhœa, 13 from scarlet fever, 10 from "fever," 6 from measles, 5 from diphtheria, and not one from small-pox. The annual death-rate from these zymotic diseases averaged 2·4 per 1000 in the eight towns, and was 0·9 below the average rate from the same diseases in the twenty large English towns. This zymotic death-rate ranged in the eight Scotch towns from 1·3 and 2·1 in Dundee and Paisley, to 3·5 and 3·9 in Leith and Perth. The 14 fatal cases of whooping-cough in the eight towns showed a decline of 5 from those returned in the previous week, and included 6 in Glasgow, 3 in Edinburgh, and 2 in Leith. The 14 deaths from diarrhœa were fewer by 4 than the number in the previous week, but in proportion to population were more than twice as numerous as in the twenty English towns. The fatal cases of scarlet fever, which had been 5 and 11 in the two previous weeks, further rose to 13 last week, of which 2 occurred in Glasgow, 8 in Edinburgh, and 2 in Leith. The 6 deaths from measles, however, all of which were returned in Glasgow, were less than half the number in the previous week. The 10 deaths referred to "fever" (including typhus, enteric, and simple) showed a further increase upon recent weekly numbers, and included 6 in Glasgow and 2 in Aberdeen. The annual death-rate from this cause in the eight towns was equal to 0·40 per 1000, and considerably exceeded the average fever rate in the twenty English towns. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) in eight towns, which had steadily declined from 140 to 89 in the four preceding weeks, rose again last week to 106, and were equal to an annual rate of 4·2 per 1000; the rate from the same diseases in London did not exceed 3·4.

HEALTH OF DUBLIN.

The rate of mortality showed an increase again in Dublin last week. The annual death-rate in the city, which had been equal to 29·9, 25·2, and 24·9 per 1000 in the three preceding weeks, rose again last week to 26·4. The rate in the city averaged 28·6 per 1000 in the first nine weeks of the current quarter, against 20·7 in London and 20·6 in Edinburgh. The 169 deaths in Dublin last week showed an increase of 10 upon the number in the previous week, and included 12, or rather more than 7 per cent., which were referred to the principal zymotic diseases, against 14 and 13 in the two preceding weeks. Of these 12 zymotic deaths, 7 resulted from "fever," 4 from scarlet fever, and 1 from diarrhœa, whereas not one was referred either to small-pox, measles, diphtheria, or whooping-cough. The annual death-rate from these principal zymotic diseases did not exceed 1·8 per 1000, while the rate from the same diseases was equal to 3·8 in London and 3·3 in Edinburgh. The deaths referred to "fever" (including typhus, enteric, and simple) in Dublin, which had been 7 and 9 in the two previous weeks, declined again to 7 last week, but were equal to a rate more than four times as high as the average rate from the same cause in the twenty large English towns. The 4 deaths from scarlet fever exceeded the numbers returned in recent weeks. The deaths of elderly persons corresponded with the number in each of the two previous weeks, whereas those of infants showed a further considerable decline.

THE HEALTH OF ROME.

A letter from the Rev. H. W. Wasse, Chaplain in Rome, which appeared in *The Times* of Wednesday last, aptly illustrates the danger of writing on health statistics without full acquaintance with the import of figures relating to this subject. The object of the letter is stated to be to counteract the effect of reports "as to the unhealthiness of Rome during the past season." Mr. Wasse's facts are, first, that among English Protestant visitors six deaths have occurred within the city since October last. Now, this information is absolutely valueless unless the number of such visitors was known, and even their bare number would not be much assistance, as it would be unwise to accept the crude death-rate among a fluctuating number of visitors of unknown ages as any test of the health condition of the city. Unfortunately, however, for the sanitary reputation of Rome, Mr. Wasse goes on to state, in the second place, that of those six deaths among English Protestant visitors since October two resulted from typhoid fever and one from diphtheria; in other words, that fifty per cent. of those deaths were referred to diseases of generally acknowledged filth origin. Well might the Roman authorities wish to be protected from their friends. It appears from the official returns of mortality statistics published in Rome, which are reproduced in the Registrar-General's Weekly Return, that the annual death-rate in that city during the first half of the current quarter averaged 26·6 per 1000, showing a marked decline from the rate that prevailed during the first quarter of the year. The recent death-rate in Rome, although showing a large excess upon the average rate in large English towns, does not compare unfavourably with the death-rates in most other European cities. The fatality both of typhoid fever and diphtheria very considerably exceeds that recorded in English towns, but has recently been below the Roman average. Small-pox caused 103 deaths between the 1st of January and the middle of May, but this disease was considerably more fatal in London during the same period.

THE SERVICES.

ARMY MEDICAL DEPARTMENT DINNER.

THE officers of the Army Medical Department held their first annual dinner on Saturday last at the Inns of Court Hotel, Sir William M. Muir, K.C.B., Director-General, in the chair. Nearly one hundred officers, past and present, attended, including Sir Galbraith Logan, K.C.B., Surgeon-Generals T. Longmore, C.B., A. Shelton, W. Rutherford, C.B., H. H. Massy, C.B., S. Fasson, R. Lawson, W. Maclean, C.B., J. A. Fraser; Deputy Surgeon-Generals C. D. Madden, J. Irvine, J. Hendley, C.B., F. Holton, J. P. Cunningham, J. O'Nial, C.B., T. W. Fox, J. E. Moffatt, J. Crerar, P. S. Laing, G. Anderson, J. Jee, V.C., C.B., J. Mure; Brigade-Surgeons J. B. C. Reade, J. Ekin, L. Kidd, G. M. Slaughter, O. Barnett, C.I.E., F. Collins, J. C. Johnston, J. Johnston, J. Adcock, E. D. Tomlinson, W. Creagh; Surgeon-Majors R. W. Jackson, C.B., H. R. Veale, T. N. Hoysted, A. F. Bradshaw, E. F. O'Leary, C. Mackinnon, I. Inkson, J. Warren, W. G. Don, W. C. Boyd, J. S. Comynd, F. Scanlan, T. Walsh, T. M. O'Brien, A. J. Ferguson, E. Hoile, A. Allan, J. E. Clarke, S. K. Ray, G. E. Will, C. H. Godwin, C. A. Maunsell, F. B. Scott, W. Nash, W. T. Martin, F. Howard, M. Cogan, J. Candy, A. F. S. Clarke, J. Maturin, R. Tobin, G. Evatt, H. W. Mackinnon, J. L. Notter, S. Moore, J. Macartney, T. J. Gallwey, J. D. Gunning, G. E. Dobson, J. Walker, E. V. MacSwiney, W. Gasteen, T. Ligertwood, J. G. Randall, G. C. Gribbon, J. E. Purdon, P. H. Johnston; Surgeons J. M. Beamish, H. Bradford, J. A. Smith, J. Martin,

H. A. Fogerty, J. Forrester, S. H. Carter, H. C. Kirkpatrick, H. Grier, C. C. H. Smith; Professors F. de Chaumont, F.R.S., W. Aitken, F.R.S., Flower, F.R.S., late 63rd Regiment; Drs. Farquharson, M.P., late Coldstream Guards, Pearson, late Rifle Brigade. Dr. Reid, Director-General of the Naval Medical Department; and Sir Joseph Fayrer, K.C.S.I., were guests of the officers.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major James Bonnyman, M.D., has been granted retired pay, with the honorary rank of Brigade Surgeon.

Deputy Surgeon-General M. F. Manifold, Surgeon-Majors W. L. Farmer, B. J. Jasdowski, A. J. Bartley, and R. W. Hinds are on passage home from India in H.M. troopship *Euphrates*, which left Bombay on May 11th. Brigade Surgeon J. W. Hulseberg and Honorary Surgeon Munday of the Bengal Medical Service have been provided with passages in the same ship.

Surgeon-Major A. F. Preston, who was severely wounded at the battle of Maiwand, has been granted extension of leave from April 16th to October 16th, by the Commander-in-Chief in India.

Deputy Surgeon-General Simpson, Bombay Medical Service, has been appointed Principal Medical Officer of the South-Eastern Afghan Field force at Quettah.

Surgeon J. T. Carey, Army Medical Department, has been granted six months leave from India on urgent private affairs.

ADMIRALTY. — The following appointments have been made:—Staff Surgeon William D. Isaac, to the *Urgent*, vice Beale, sent home in the *Humber* in charge of invalids; Staff Surgeon William Galloway, M.D., to the *Griffon*, vice William D. Isaac; and Staff Surgeon St. Lawrence Ffrench Mullen, M.D., to the *Dasher*, vice William Galloway, M.D., in lieu of a surgeon; Surgeon E. W. Luther, to the *Warrior*, vice F. R. M. Loftie.

THE INODOROUS PROCESS OF EMPTYING CESSPOOLS.

FOR the last nine months a company, called the "Société Anonyme des Vidanges Inodores à Vapeur de Paris," has been employed in Paris in emptying the cesspools with which that fair city abounds, by a novel, economical, and, in a sanitary point of view, a most admirable system, abolishing not only the filthy smells, but all the somewhat loathsome concomitants connected with night-soil men and their appliances. Anyone who has experienced the disgusting stench arising when cesspools are emptied in the ordinary way, must acknowledge that any plan which can effect the object with rapidity, cleanliness, and perfect immunity from smell of any description, is worthy of fair trial, and, if proving to do all it professes, of being regarded as a very great boon in sanitary reform. We had an opportunity last week, through the courtesy of the directors of the company, conveyed through T. Lawrie, Esq., of witnessing a practical test of the system at Kew. The process has been patented by M. Talard, one of the inventors, who was present at the trial, and who, with Mr. Lawrie, gave a clear explanation of the machinery and plant used in the system, before the experiment commenced. The following is a brief description of the apparatus used.

1. A small portable locomotive engine of five-horse power, fitted with a steam vacuum pump.
2. Receivers, made of light steel plates, barrel-shaped, and of a capacity of about three and a half cubic yards. They are mounted on four wheels, and are easily drawn by a pair of horses. A glass indicator is fitted at one side to show when the receiver is full, and at the lower end behind is a valve to which a flexible tube is attached.
3. A large covered waggon for stowing the pipes used in extracting the sewage; these pipes are partly flexible, partly galvanised iron, made in convenient lengths and fixed together by a remarkably ingenious lever joint, very simple and yet, with an india-rubber disc, quickly and hermetically sealing the end. The tubes are five inches in diameter; one of them is fitted with a protected glass box, so that the contents of the cesspool can be seen as they pass through. (It was stated that in Paris the body of an infant, a bunch of keys, a gold watch, and other articles had been detected passing through and recovered.)

The process of emptying the cesspits may be described as consisting of pumping the excreta by atmospheric pressure into the receivers, from which the air has been previously exhausted. So far the plant used. At Kew, a cesspit which was estimated to contain about five tons of sewage, and which had not been cleaned for twelve months, was selected for experiment. The engine was placed a short distance, some five or six yards, from the pit, which was in a garden close to an empty mansion; the pipes were taken from the waggon and connected together, one end fixed to a receiver, which was drawn up adjacent to the engine; the other plunged to the bottom of the cesspit; a canvas cover protecting the hole in the pit's mouth, and preventing the escape of any noxious gas. The pipes which connect the engine and receiver are flexible, two inches in diameter; these being attached, the engine was started. Should fetid gases exist, they are first extracted from the cesspits, passed through the furnace and burned. The receiver was then exhausted of air by the pump, and the valve opened; the contents of the cesspool rushed up, filling the vacuum in three minutes and a half; the valve was then closed, the pipes disconnected, and the receiver taken away, to be replaced by a second, until the pit was empty. Each receiver holds nearly four tons of matter, and the one under operation was full in less than the same number of minutes; two minutes more sufficed to clear the pit of its remaining contents. No smell of any kind was detected during the operation. The pipes were then sluiced with water and repacked in the waggon, the two receivers were drawn away by horses, and the trial, which was witnessed by a large number of scientific gentlemen, was finished, universal opinion being expressed that it was most satisfactory, and had thoroughly borne out the superiority claimed for the system by its inventors. It will be asked what is done with the receivers and their contents. In Paris they are discharged into closed barges, specially constructed, and which finally empty the sewage into the Seine. But they can equally be carried to farms and used for fertilising purposes, or discharge the sewage into filtering tanks, or taken to the coast for final disposal, according to local arrangements and requirements. It may be added that only four men are required to work the process, and the cost paid at present in Paris by the municipality to the company is five francs per cubic metre, or about 3*s.* 6*d.* per cubic yard; the cost in England is stated to be never less than 10*s.* per cubic yard. Another advantage claimed for the system is its workability by day. The trial we witnessed extracted, as before stated, five tons of sewage matter in about six minutes without dirt, smell, or annoyance of any kind. The pipes can be laid from a cesspool wherever situated, and, if necessary, could pass through a room without causing any disagreeable odour; the occupants unless told would be unaware that anything of an unpleasant nature was being done. The company, we understand, contemplate working their patent in this country, and from our observation at Kew, we cannot but think the process is worthy the attention of all interested in sanitary work.

THE SANDERS MEMORIAL.

AT a meeting of members of the medical profession held in the hall of the Royal College of Physicians of Edinburgh on the 23rd ult., resolutions were adopted to the effect that expression should be given to the esteem in which the memory of the late Professor Sanders is held, by the erection of a permanent monument; and that a committee, consisting of Dr. Haldane, Mr. Imlach, and Professor Maclagan, be appointed to consider in what manner this object may best be carried out, and to raise the necessary funds for doing so. This committee has now recommended that the memorial should consist of a monument, to be erected over the grave, and that drawings should be obtained from John Hutchison, Esq., R.S.A., of a monument, of which a bust, or medallion in high relief, of Professor Sanders should be a prominent feature. It has been ascertained that such a work would cost not less than £300 The drawings will be submitted to a general meeting of subscribers. Intimation of subscriptions may be made to the honorary treasurers and secretaries, Dr. J. Batty Tuke, 20, Charlotte-square, Edinburgh; and Dr. Blair Cunynghame, 6, Walker-street, Edinburgh.

ROYAL COLLEGE OF SURGEONS.

AT an ordinary meeting of the Council of the Royal College of Surgeons, held on Thursday last, the report of the Committee for the nomination and appointment of examiners was received and adopted, after some discussion relative to the appointment of *substitute* examiners. The report of the President and Vice-Presidents of the Erasmus Wilson Fund was received and adopted. Mr. Marshall was unanimously appointed representative of the College in the General Medical Council as successor to Sir James Paget, resigned. The present professors and lecturers were nominated for re-election in July. A letter from the General Medical Council, relating to a compulsory preliminary scientific examination, was referred to the committee on further preliminary examinations, to consider and report thereon to the Council. A letter from the secretary to the Royal Commission on the Medical Acts was read, and the President and Vice-presidents were requested to take such further steps as they might deem necessary to secure a proper representation of the interests and opinions of the Council. There was a strong expression of opinion that the secretary, Mr. Trimmer, should be one of the representatives of the College to give evidence before the Commission.

IRISH MEDICAL ASSOCIATION.

THE annual general meeting of this association was held in the Royal College of Surgeons in Ireland on Monday the 6th inst. The report stated that since the last annual meeting, the Registration of Births and Deaths Amendment (Ireland) Act had become law, and the Council, while regretting that some important clauses in the Bill were struck out, regard the Act, which affords a much more perfect system of registration, as a decided improvement in the law. The Bill to amend the law relating to medical charities in Ireland was not favourably received in the House of Commons, and it had been deemed better to have it withdrawn until the Legislature is more fully informed as to the nature and extent of the abuses to which the present system of Poor-law medical relief is subject. It was hoped that a measure would then be introduced which shall define clearly who are to be eligible to receive dispensary medical relief, the term "poor person" now adopted being too vague, and thus a stop may be put to well-to-do or comparatively wealthy ratepayers obtaining medicine and medical attendance gratuitously. The Council were gratified to report that the Bill for the amendment of the Vaccination Act was withdrawn. The question of superannuation had exercised the attention of the Council, and a deputation had an interview with the Chief Secretary for Ireland, and acting on his suggestion a Bill had been drawn up for presentation to Parliament, which had since been handed to Mr. Meldon and other members to introduce. The proposed Bill seeks that the provisions of the Superannuation Act of 1879 shall be extended in a slightly modified manner to the medical officers of the Poor-law services. The subject of the compulsory notification of infectious diseases had also occupied the Council, and last year a series of resolutions were adopted, which, while recognising the advantage of an efficient system of early and compulsory notification of infectious diseases, protested emphatically against the onus of such notification being imposed upon medical practitioners, and suggested that such duty should attach to the householders, for whose benefit the advantages of the proposition were intended. The Bill introduced by Messrs. Gray and Brookes was considered objectionable in some of the provisions, and measures were taken to endeavour to have the Bill modified, or rejected if necessary. Reference was also made in the report to the Lunacy Law Association (Ireland) Bill, and the Bill to amend the Coroners (Ireland) Act; and a scheme had been drafted proposing that all new entrants into the Poor-law medical service under the age of forty shall be obliged to contribute a small annual payment to a fund from which an annuity to each widow and orphan shall be payable, with an optional power to those at present holding office to become contributors to the fund on certain conditions. The report having been adopted, resolutions were carried to the effect that the Association is of opinion in reference to the Medical Act (1858) Amendment Bill now before Parliament, that no alteration of the existing law can be satisfactory which does not provide for a sufficient degree of professional competency, guaranteed by a uniform curriculum of study and examination, as well as by similarity of fees throughout the kingdom, a reconstitution of the General Medical Council, and adequate representation of the profession at large in that body; that poor-law medical officers are equitably entitled to superannuation as civil public servants; that the existing system under which medical relief tickets are granted has been productive of gross abuses, and that the Council be requested to seek a legislative remedy for the present system; that the scheme proposed for making provision for widows and orphans of poor-law medical officers is a desirable one; and that the extension to Ireland of the English system of inspection of vaccination, and the granting of rewards for excellence in results, is practicable and desirable, and would prove highly advantageous to the public interest.

The members, with some guests, dined together in the evening in the Albert Hall of the College of Surgeons.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Friday, June 3rd, petitions were presented from Joseph West, asking for inquiry to be made into the Vaccination Acts; also petitions from London and Devonport for the prevention of vivisection. An address was agreed to for a copy of a letter from the general commanding the forces in Ireland as to the expediency of extending the application of the Contagious Diseases Acts to Dublin, and the return was subsequently presented.

Correspondence.

"Audi alteram partem."

THE COLLEGES OF PHYSICIANS AND SURGEONS AND JOINT EXAMINATION.

To the Editor of THE LANCET.

SIR,—The feeling in England in favour of having some kind of joint board has its just root in the objection to the state of the law which permits registration on a partial qualification, and in the desire to see the Colleges of Physicians and Surgeons form a joint examination. The Colleges of Physicians and Surgeons of Edinburgh formed a joint examination twenty years ago; but, though thus far in advance of the London colleges, the weak point there is that the colleges continue to examine separately for their separate licences, on one of which registration may be effected. When I ask my friends of the Edinburgh corporations why they do not resolve to drop the separate examinations, the answer is they are afraid the London colleges would not follow their example; and when I ask friends of the London colleges why they do not voluntarily form a joint examination, and refuse the issue of partial qualifications, a like answer is made—that they are afraid the Edinburgh corporations would not do so. Each stands hesitating on the bank, afraid to take the plunge, though it must be now evident that the corporations must either take this step or be superseded.

Were such a junction for examination formed voluntarily, and a Registration Act passed requiring a complete qualification before registration, the licensing difficulty would be virtually at an end. I am satisfied, from what I have heard from members of the corporations of London and Edinburgh, that both are desirous of taking the step, and I am persuaded that if the mistrust were put aside an understanding might readily be come to by which both would feel free to proceed to form such a joint examination. No one who appreciates the value of these corporations to the profession, and who knows the honourable spirit which actuates their leaders, notwithstanding much that the public is asked to believe to the contrary, can wish to see the Colleges of Physicians and Surgeons put aside, if they will only move on with the times.

But if they still hesitate to resolve on the step before the Royal Commission has them in hand their fate seems inevitable. I am, Sir, your obedient servant,

Aberdeen, June 6th, 1881. JOHN STRUTHERS.

SOLDIERS WIVES AS NURSES.

To the Editor of THE LANCET.

SIR,—With reference to the annotation in your journal of last week, page 925, on the subject of the employment of soldiers' wives as nurses, you truly observe "this importtant step was taken by an army medical officer in Dublin a few years ago;" but the real origin of this movement—viz., providing each regiment with qualified nurses—was as follows, and as some little fuss has recently been made over the subject at Woolwich, it may not be uninteresting to your readers to know the exact facts.

Some thirty years ago I was the surgeon of H.M. 9th Regiment, not long returned from India, and at the time quartered in Ireland. The regiment contained a very large proportion of women married without leave, and as the assistant-surgeon was in delicate health, a considerable amount of very troublesome night work was thrown on my shoulders. It occurred to me that the employment of one or more soldiers' wives—if educated for the purpose, in the very legitimate work of attending on their own sex—would relieve the medical officers of much troublesome and unpleasant duty, and at the same time confer a benefit on these poor women and children. I therefore addressed a letter to the C.O., the late Col. Davis, C.B., for transmission to the Secretary of State for War, pointing out the advantages both to the officers and soldiers' wives of having an educated midwife in each regiment. The reply was not unfavourable to the suggestion, but it pointed out there were no funds available for such a purpose! Ultimately permission was obtained to take a small sum, £20, from the canteen fund. An intelligent sergeant's wife was selected by me, and, after a short preliminary training, sent to the Rotundo Lying-in Hospital for final training, and in six months returned to the regiment as a qualified nurse. Her services proved so eminently useful and satisfactory, that when the regiment was proceeding on foreign service it was deemed advisable to educate another woman for the same purpose; but the War Office declined to sanction a further appropriation from the canteen fund.

A subscription was then set on foot, to which the married officers cheerfully and liberally responded, and a second nurse was thus provided. Without entering into the subject of the Nightingale nursing controversy, I believe this to be the only legitimate and proper mode of utilising the services of soldiers' wives as nurses, considering their proper sphere of usefulness among the women and children of the regiment, and not in the wards of a military hospital.

I am, Sir, yours obediently,

J. MOUAT,

London, June 6th, 1881. Surgeon-General (retired).

A GENERAL MEDICAL INDEX.

To the Editor of THE LANCET.

SIR,—From Dr. Saundby's note on this subject, which appeared in THE LANCET of the 28th May, it would seem that some members, even of the literary portion of the profession, are not aware of the present position of the matter. Dr. Saundby suggests that international co-operation should be sought for in aid of the construction of a general index of medical periodical literature; but, fortunately, a scheme of this kind has become as unnecessary as it would have been impracticable, for the Index may be said to be in existence. Under the supervision of Dr. Billings the construction of a catalogue of the Library of the Surgeon-General's Office, United States Army, was commenced in 1873; and the first volume of the work (A—Ber) was, through the liberality and public spirit of Congress, published last year and widely distributed. Unfortunately, its title, "Index-Catalogue," by no means indicates the invaluable character of its contents. It not only supplies the list of books belonging to one of the largest medical libraries in existence, which, although itself a work of great interest, would prove so to only a limited number of persons beyond those who had access to the library, but it does far more than this; for it furnishes an index of the whole of the very large collection of periodical and serial publications contained in the library. It thus becomes a most valuable possession for the medical world at large; and if not exhaustive, is so comprehensive as to entitle it to be regarded as well-nigh complete. The second volume is now printing, and there can be no doubt that Congress, with its usual liberality, will provide the funds necessary for the publication of the remaining five or six volumes in rapid succession. The inexhaustible zeal and industry of Dr. Billings and his coadjutor, Dr. Fletcher, have thus succeeded in producing a work which will be as useful to the medical inquirer as the Catalogue of Scientific Papers of the Royal Society has proved to be to the man of science; indeed, it will be much more useful by being more detailed in its construction. How such an index will be valued and consulted can only be judged of by those who have observed the warm appreciation that has attended the publication of Neale's "Medical Digest," which yet embraces less than a dozen English periodicals. The periodical and serial publications of all times, and in all languages, which come within the grasp of the "Index-Catalogue," are numbered not by hundreds, but by thousands.

The Index-Catalogue thus renders the whole range of medical literature easily accessible down to the year 1878; and under the title "Index Medicus" its author has devised an annual supplemental volume, with the object of referring to all the articles which have appeared in each year. Two volumes of this Index have appeared, and that for 1880 is publishing in monthly parts; but although its price is moderate (25*s.*), there is great doubt whether it will be continued. For two years the spirited publisher, Mr. Leypoldt of New York, has lost considerable sums upon it, but has consented to try it for another year. With what success the appeal which was last year made to the profession has been responded to I have not heard; but if such a publication of signal utility to inquirers in all parts of the world is allowed to collapse for the want of the few hundreds necessary to secure its continuance, an opportunity will be lost not very likely to recur.

It will thus be seen that the great desideratum of a general index down to 1878 will soon be supplied, and all our energies should be turned towards securing the continuation of the Index Medicus. It is a subject well worthy of being brought before the approaching Medical Congress.

I am, Sir, yours obediently,

Royal College of Surgeons of England, JOHN CHATTO.
June, 1881.

DR. GEORGE HARLEY'S CACOGRAPHY.

To the Editor of THE LANCET.

SIR,—Many years have elapsed since my name has figured in your columns, and one reason for this has been that though I may have felt inclined to comment on communications addressed to you, I have generally found that by the exercise of a little patience some other correspondent has supplied the remarks I had to offer. Lest, however, I should be disappointed in the present instance, I lose no time in entering my protest against the singular display of unscholarly writing inserted in your last issue as the lucubrations of Dr. George Harley.

By your kind indulgence, Sir, the many have the opportunity of airing their crotchets in THE LANCET, but that now called in question is simply "out of all whooping." Reformed spelling, forsooth! Does not Dr. Harley perceive that his system entails also reformed pronunciation, and that, if ever we adopt the "Fonetik Nuz," we shall lose the derivation, and consequently the true meaning of our words?

It may be all very well for those who, from advancing years, may have forgotten much that they learned in their youth, among which orthography is perhaps one of the most notorious, to adopt that plan or licence which countenances spelling in any way that comes uppermost, and call it "reformed." But I hold that when a member of our profession addresses that body through your medium, he owes it that respect that he should solve his doubts by reference to some authorised source. I dare say I have woefully slipped behind the world, and that prepositions have come to be used differently than heretofore. Formerly we used to say "the solution *of* a cause," and not "the solution *to* a cause;" but, no doubt, *nous avons changé tout cela.*

I have been a reader of, and subscriber to, THE LANCET from its very commencement, but I candidly avow I never found in it anything that has given me so great a shock as Dr. Harley's ill-considered production.

Yours faithfully,
JOHN CHIPPENDALE, F.R.C.S.
Upper Phillimore-place, Kensington, W., June 6th, 1881.

SMALL-POX HOSPITALS.

To the Editor of THE LANCET.

SIR,—The *raison d'être* of the small-pox hospitals was to afford depôts for the segregation and isolation of all cases of that disease, and so prevent the spread of infection from individual to individual. How far such hospitals, as at present constructed and managed, have answered this purpose—how, as isolation depôts, they have proved themselves thorough shams—the following statistics of the neighbourhood of the Fulham Hospital will irrefutably show:—

Hospital receiving convalescent cases only, for three months up to Dec. 25th, 1880.		*Hospital fully opened for acute cases, for three months ending March 25th, 1881.*	
Kensington[1]	2	Kensington	87
Chelsea[1]	3	Chelsea	73
Fulham[1]	3	Fulham	97

Thus showing that since the opening of the hospital for acute cases small-pox has been more than thirty-two times as rife as before.

At the commencement of the present year every practitioner living within the mile radius of the Fulham Hospital was asked by the Local Government Board to send in a record of every case coming under his cognisance between Dec. 25th, 1880, and March 25th, 1881. In other words, the outbreak, if any should occur, after the re-opening of the hospital for acute cases should be regarded in the light of an experiment that would most decisively affirm or negative the contention that small-pox hospitals are in themselves the originators of the oft-recurring and irrepressible outbreaks in their neighbourhoods.

It is now more than two months over the date assigned for the ingathering of these statistics, and the Local Government Board has not thought fit (in a matter so vital to the health of the community) to publish, whether in their favour or not, the deductions they have drawn from them.

I am, Sir, your obedient servant,
ALFRED GODRICH, M.A., M.R.C.S., &c.
Fulham-road, June 6th, 1881.

CLINICAL TEACHING AT ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

To the Editor of THE LANCET.

SIR,—In your issue of last week is a letter respecting clinical teaching at Addenbrooke's Hospital, Cambridge. It seems to me that requiring students, ignorant of anatomy and physiology, to attend, or, rather, to obtain benefit from attending, clinical lectures, is about on a par with expecting a man to appreciate the binomial theorem without a knowledge of the elementary facts of algebra and arithmetic. In any revision of the system of medical education, it seems to me that the first two years of student life should be spent in learning the scientific portion of a medical education, such as anatomy, physiology, chemistry and physics—if these two latter could not be learnt at school—materia medica and pharmacy; taking care these subjects are thoroughly learnt.

Then the next two years, or more if the student can spare time and money, would be devoted to medicine and surgery, medical jurisprudence and therapeutics (as something over and above materia medica). During these last two years clinical lectures and teaching would be thoroughly appreciated, especially if given by such accomplished professors as are at Cambridge. Then I would have each student, before he be allowed to practise on his own responsibility, be required to bring a certificate of having acted as assistant to a Poor-law medical officer, or to have had charge of patients at some dispensary where the sick are visited at their own homes. This period should last at least six months. Judging from my own personal experience and the effects produced on my brother, who is now at Addenbrooke's Hospital, no good results from clinical teaching before a knowledge of anatomy and physiology is obtained. During my own student life, now some eighteen years ago, I tried to carry out this system; and to show that it was not altogether unsuccessful, I may be allowed to sign myself

ONE WHO TOOK HONOURS IN ALL SUBJECTS AT THE SECOND M.B. EXAM., UNIV. OF LOND.
June 6th, 1881.

A NEW ANTISEPTIC.

To the Editor of THE LANCET.

SIR,—In your issue of May 21st you published some remarks upon the recent important proposal of Professor Lister relative to eucalyptus oil, and in view of the interest thus excited the following notes may be found to have some value.

Dr. Gimbert of Cannes used for many years the leaves of the Eucalyptus globulus, instead of lint, for dressing wounds, with excellent results. He also described many experiments illustrative of the anti-putrescent properties of the oil of eucalyptus.[1] M. Gubler[2] and M. Marc have also both testified to the same effect, and employed an aqueous infusion of the leaves with great success in purulent catarrhal affections of the urethra and vagina. Again, Mr. Stearus, in a report[3] upon the oil of eucalyptus, writes, "Its chief value, however, is as a sedative and antiseptic in asthma and throat diseases, nasal catarrhs, and affections of the mucous membranes." He used both the alcoholic tincture and the spray of the pure oil.

Further, a "Report of the United States Commissioner of Agriculture"[4] embodies a number of experiments bearing upon the antiseptic and oxidising properties of the oil of eucalyptus, and in explanation of these latter the reporter accepts the writer's investigations which have from time to time been communicated to the Chemical Society of London and elsewhere.

I think I may fairly claim to have placed the antiseptic and oxidising properties of all the essential oils upon a scientific basis; and those of your readers who may care to become acquainted with the whole history of the Eucalyptus globulus and the characters and chemistry of the essential oils, I beg to refer to my "Nature's Hygiene,"[5] in which volume I have incorporated the entire results of my investigations so far as these had extended up to the end of 1879.

I now come to another and more important matter, and that is to announce the discovery of what is, I believe, a better antiseptic than oil of eucalyptus for use in surgery; at the same time it is chemically allied to that substance, and but for economical considerations can be produced therefrom. The product to which I refer is an oxidised oil of turpentine; in other words, the product which I obtain by forcing a current of air through turpentine in the presence of water (or otherwise) during a prolonged period, lasting in practice from one to two hundred hours. By this process of air-oxidation the turpentine absorbs an enormous quantity of oxygen, increasing in density accordingly, and losing its very volatile character. Although the product is not strictly speaking soluble in water, it forms in contact therewith, or even in contact with any moist surface such as is presented by every wound, certain principles which pass into aqueous solution. These principles are strongly antiseptic, and amongst them peroxide of hydrogen is to be numbered.

My product is much cheaper than oil of eucalyptus, it is more intensely antiseptic, and is, as I have shown, free from the objections which you, Sir, have already pointed out to exist in the case of the eucalyptus oil. It is freely soluble in spirit, and is perfectly miscible with other oils, and with petroleum bases, &c. A gauze can be readily made from it which keeps its strength, so far as I can judge, very well; and what is of much importance, it is a very powerful oxidant as well as an antiseptic. Thus we have a quite new combination, which I earnestly trust will be found available for the purposes of antiseptic surgery.

---

[1] These were sent from the three neighbouring parishes.

[1] See Pharm. Journ., vol. iv., p. 494.

[2] Journ. de Pharm. et de Chimie, Dec. 1871.

[3] Contributed to the Californian Academy of Science in July, 1872.

[4] An extract from which is given in the Pharmaceutical Journal, Jan. 12th, 1878.

[5] Published by Messrs. Baillière, Tindall, and Cox, 1880.

I should add that, beyond my own investigation of its anti-putrescent and other properties, these have also been examined and certified to by Professor Roscoe, LL.D., F.R.S., of the Owens College, Manchester, and President of the Chemical Society, and Professor T. E. Thorpe, F.R.S., of the Yorkshire College, Leeds.

Finally, I may, perhaps, mention that Professor Lister has very kindly undertaken to make trial of the product.

I am, Sir, yours faithfully,
C. T. KINGZETT, F.C.S., F.I.C.,
Author of "Animal Chemistry, or the Relations of Chemistry to Physiology and Pathology," &c.
Tottenham, N., June 4th, 1881.

MANCHESTER.

(From our own Correspondent.)

I AM glad to see that the Infirmary Board have at their last meeting instructed their secretary to write again to the Paving Committee of the Manchester Corporation, calling their attention to the subject of paving with wood, or other noiseless material, the thoroughfares round the Royal Infirmary. Doubtless this will be done at once; and while on this matter I would like to draw attention to the fact that St. John-street, in which the Eye Hospital and the Consumption Hospital are situated, is still unprovided with noiseless pavement, and that opposite St. Mary's Hospital only *one-half* of the breadth of the street is paved with wood. Now that the weather is hot and windows are kept open, the noise of the traffic over the granite setts is deafening and very detrimental to the welfare of the patients who have to lie on a bed of pain the livelong day, listening wearily to the grinding past of heavenly laden vehicles, longing for an interval of rest which never comes. I am sure this state of matters need only to be brought under the notice of the Corporation to be remedied at once.

It is reassuring to be told, now that we are on the brink of a possible epidemic of small-pox, that the accommodation at Monsal Fever Hospital is ample for at least ten times the number of infectious cases that have been received on an average during the last three or four months; and that, in addition to this, there is unoccupied land contiguous to the hospital, upon which temporary hospital accommodation could be provided sufficient for the needs of the whole population of Manchester and the surrounding neighbourhood. The Infirmary authorities deserve all credit for the manner in which they have dealt with the subject of provision for the treatment of infectious diseases in this city.

A very important meeting has just been held by the Medico-Ethical Association, to inquire into the present working and management of the Provident Dispensary scheme in Manchester. Several very remarkable revelations were made as to the management of the dispensaries and the method of obtaining members. The whole question was referred to a committee, which it is to be hoped will thoroughly investigate into the alleged abuses, and remedy them by an appeal to the committee of the Provident Dispensary Association—a body which is composed of gentlemen of standing in this city, and who would be the last in the world to put themselves in antagonism with the medical profession.

I observe that Dr. Glascott commences his summer course of ophthalmoscopic demonstrations at the Royal Eye Hospital next week. This course, which is given as a supplementary one to Dr. Little's systematic course of ophthalmology at Owens College, was well attended and much appreciated by the students last year, and owed much of its usefulness and interest to the large number of ophthalmoscopic cases examined by the class, each member being practically instructed in the use of the ophthalmoscope and allied methods of investigation of deep-seated eye disease.

GLASGOW.

(From our own Correspondent.)

THE new wing of the Western Infirmary, which gives two hundred beds additional, or, in fact, doubles the accommodation of the institution, was formally opened a few days ago. This new wing has been built with funds left by the late Mr. John Freeland, of Nice, whose family was one of the oldest in Glasgow, the name of his father's firm appearing in a directory of more than a century ago, and existing till within the last few years. In the course of a speech made at the opening ceremony, the Lord Provost stated that even yet there is a deficiency of hospital accommodation in Glasgow, and referred to the effort which is being made to have a hospital erected on the south side of the city. He showed that, as regards the number of available hospital beds, Glasgow is far behind other large cities, and expressed a hope that any further increase made would not be accomplished by adding to the two existing infirmaries, which are large enough already, but by the erection of a hospital elsewhere.

The Hon. John Ure, Lord Provost of Glasgow, has issued a pamphlet, full of sound practical suggestion, in support of a movement on the part of the cities and large towns of Scotland for the amendment of the Public Health (Scotland) Act, 1867. He advocates, in the first place, a reconstitution of the Central Health Authority, on the ground that its present constitution affords no guarantee that it will efficiently administer public health functions; and proposes either that the present Board of Supervision should be cast aside altogether, and that the care of the public health in Scotland should be entrusted to a separate State department, or that the existing Board of Supervision should be strengthened by the addition to its membership of some who have made sanitary science a special study. The vesting of the powers of local authority in the parochial boards is shown to result, in rural districts, in very lukewarm enforcing of the Act, sometimes in its complete neglect. The rural sanitary areas, therefore, should be enlarged, either on the basis of the county or by combination of parishes, so as to secure administration beyond local influence. The following are some of the changes which Mr. Ure proposes should be made in the scope of the Health Act itself: that enlarged powers over the erection of new buildings should be conferred on the sanitary authorities; that compulsory hospital accommodation be provided in every district; that the registration of infectious diseases within each district should be compulsory; that the milk trade be put under the supervision of the sanitary authorities; that the supervision and enforcement of the Vaccination Act be transferred to the sanitary authorities; that the medical officer and sanitary authorities obtain power to make inquiry into the cause of any uncertified death.

IRELAND.

(From our own Correspondent.)

THE annual meeting of the Fellows of the Royal College of Surgeons to receive and discuss the report of the Council for the past year was held on Saturday last, and was largely attended. The proceedings commenced with a resolution being proposed by Dr. Jacob and seconded by Dr. Martin, to the effect that the annual report was unsatisfactory, and that for the future a *précis* of the proceedings of Council should be sent quarterly to the Fellows for their information. It appears that a resolution had been adopted by the Council last year to carry out this arrangement, but in January last was rescinded, yet not the slightest reference to this important subject was included in the annual report—a convincing proof, if any were required, that the report sent to each Fellow excludes a large number of topics which those taking an interest in the proceedings of the College may never have an opportunity of becoming acquainted with. The only excuse given for not issuing a quarterly summary of the proceedings of Council appears to be the trouble of making an abstract and the expense. On a show of hands being called for, 26 voted for the resolution and 11 against, the result being that the recommendation that quarterly abstracts should be issued will be brought before the new Council at their next meeting. After some criticisms on the manner in which the financial part of the report was presented, Dr. Mapother, a member of Council and ex-president of the College, proposed a resolution that it be recommended to the Council that the Education Scheme as amended in committee should not be enforced until equivalent regulations had been adopted by a majority of the other licensing bodies, and that a scheme should be prepared in conformity with the recommendations of the General Medical Council. He paid a high compliment to the thought and labour given to the scheme, but believed that it would have a most prejudicial effect on the finances of the College by reducing the number of the candidates for the licence, and urged that its adoption should be deferred, more especially as the Royal Commission now sitting would most probably suggest a measure which could be generally adopted. Further, he showed the mistake of placing such subjects as the elements of chemistry and botany in the first professional examination without requiring certificates of having attended lectures in those branches of medicine, and was of opinion that the proposed scheme would be more expensive to the student than the existing regulations for the licence of the College. The resolution was seconded by Mr. Jolliffe Tufnell, who urged various reasons for deferring the adoption of the scheme. Drs. Kidd, Barton, Jacob, and others combated Dr. Mapother's statements, and were of opinion that if the new regulations were adopted they would add to the prestige of the College without diminishing its funds. The resolution was ultimately lost, the numbers being 27 against, as compared with 31 in favour of the scheme. On Whit-Monday the annual elections for president, vice-president, secretary, and council took place, when Mr. Samuel Chaplin was elected president, Mr. J. Kellock Barton vice-president, and Mr. Colles secretary. For the council the only alteration was the substitution of Mr. E. H. Bennett, professor of surgery in the University of Dublin, for Mr. F. Alcock Nixon.

At an adjourned meeting of the committee appointed to effect the establishment of a convalescent home in Dublin or neighbourhood, for the reception of persons suffering from infectious diseases, held last week, a communication was read from the authorities of the Cork-street Fever Hospital. The governors of that institution stated that they were willing to undertake the expenditure of the money obtained for the erection of the proposed home in improving and remodeling their accommodation for convalescent patients, which is at present unsuitable and inadequate; and to devote any beds not required for their own patients to similar cases sent in from other hospitals. It was resolved that a general meeting of the subscribers be held to take into consideration the offer of the governors of Cork-street Fever Hospital; and it is probable that the suggested arrangement will be adopted, as, in spite of every effort made for obtaining funds for a convalescent home for infectious diseases, the donations so far have been altogether inadequate for the purpose.

At the distribution of the Hudson Scholarship Prizes connected with the Adelaide Hospital, Dublin, last week, the first prize of £30 and a gold medal was awarded to Mr. E. Gordon Hull, and the second of £10 and a silver medal to Mr. F. W. Elsner. During the meeting Dr. James Little gave an interesting outline of the career of the late Dr. Alfred Hudson, in whose memory these scholarships have been founded.

Dr. Cameron, medical superintendent officer of health for Dublin, last week gave the second of the series of lectures on health, which are now being delivered under the auspices of the Ladies' Sanitary Association, in the theatre of the Royal Dublin Society. "Food" was the topic selected, and the lecturer described the composition of the different kinds of food and drink, illustrating his remarks by means of diagrams, specimens, and experiments. He referred also to the processes of digestion, and gave some valuable information on the subject of cookery.

Dr. Joseph E. Miller, J.P., of Derry, has been presented with an address and valuable piece of plate by the Derry Town Council and citizens, on resigning the office of alderman, which he has held for nearly half a century. Dr. Miller, I may add, has been elected Mayor of Derry on five successive occasions.

The June medical examinations of the Queen's University in Ireland commenced last Monday, and will terminate on the 20th inst. A meeting of the University to confer degrees will be held in Dublin Castle on the 20th inst.

The thirty-ninth annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held in the College of Surgeons last Monday, the chair being occupied by the President, Dr. McClintock, who regretted that the amount at their disposal for distribution for the present year fell short of the sum granted last year. It was therefore a matter of congratulation that the Society had about £17,000 invested, which returns an annual income of some £600. The committee in their report state that anticipatory grants to urgent cases had been given to the amount of £153; of the claimants three were medical men, and vouched to be in absolute distress. Further grants to the amount of £976 have been now allocated, making the total sum of the awards recommended since last report £1129, of which £340 was to medical men, £691 to widows, and £98 to orphans. The committee, in referring to the fact that there must be some 1500 medical practitioners in Ireland who do not contribute anything to the Fund, remark that the Society has to contend with deplorable apathy amongst those from whom it should naturally expect the warmest sympathy—namely, the provincial medical men. The office-bearers having been appointed for the ensuing year, a vote of thanks to the Chairman for presiding terminated the proceedings.

Obituary.

CHARLES HARRIOTT ROPER, M.R.C.S. ENG.

MR. ROPER, whose death, after a painful illness, took place on the 23rd ult., was the son of the Rev. R. Roper, Principal of Mount Radford House School, and Rector of St. Olave's. He pursued his professional studies at the Devon and Exeter Hospital, and afterwards at St. Bartholomew's, where he distinguished himself as a prize-winner. After obtaining his diploma as Member of the London College of Surgeons and his Apothecaries' licence, he commenced practice at Exeter, where he remained till his death. Mr. Roper was a Fellow of the Royal Microscopical Society, held the post of Senior Surgeon of the Devon and Exeter Hospital, and of the Lying-in Charity, besides other appointments in the neighbourhood. He had also at different times occupied important civic positions in Exeter. Such a man could not pass away without being greatly missed, and Mr. Roper's loss will for long be acutely felt by numerous patients and a large circle of friends.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members having passed the required examination for the Fellowship on May 26th, 27th, 28th, and 30th, were, at a meeting of the Council held on the 9th inst., duly admitted Fellows of the College.:—

Bowlby, Anthony Alfred, L.S.A., Warrington-crescent; diploma of Membership dated July, 1879.
Boyd, James Stanley Newton, M.B. Lond., Huntley-street, Bedford-square; July, 1878.
Burton, Samuel Herbert, M.B. Lond., St. Giles-Street, Norwich; January, 1876.
Carter, Fredk. Heales, L.S.A., Bellevue-road, Upper Tooting; July, 1875.
Crew, Wm. Thomas, L.R.C.P. Lond., Park-lane Macclesfield; July, 1879.
Heath, William Lenton, The Plains, Totnes; July, 1877.
Pollard, Bilton, M.B. Lond., West Dulwich; November, 1879.
Reid, Robert William, M.D. Aberdeen, Nottingham-place, Regent's-park. (Not a Member.)
Sheppard, Charles Edward, M.B. and L.R.C.P. Lond., Addison-gardens; July, 1877.
Symonds, Charters James, M.D. Lond., St. Thomas's-street, Southwark; July, 1875.
Turner, Edward Beadon, L.R.C.P. Lond., Sussex-gardens, Hyde-park; July, 1876.
Wadham, Frederick, L.R.C.P. Lond., Bayhorne, Horley; Nov. 1878.
Williams, William Roger, L.R.C.P. Lond., Bush Hill-park, Enfield; April, 1877.
Williamson, Robert Isherwood, M.B. Oxon., L.R.C.P. Lond., Ripon, Yorkshire; April, 1879.
Willis, William, M.D. Edin., Oak House, Monmouth; July, 1858.

Two other candidates passed the examination, but, being under the legal age (twenty-five years), will be admitted Fellows at a subsequent meeting; and ten candidates failed to reach the required standard, and were referred for one year's further professional study.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 2nd:—

Cooney, John Edwin, Calcutta.
Sykes, Matthew Carrington, Barnsley.

The following gentlemen also on the same day passed the Primary Professional Examination:—

James B. Brewitt, St. Bartholomew's Hospital; Richd. Philip Samut, Guy's Hospital.

OVER fourteen tons of bad meat were seized last week in the Holborn district.

CAMBRIDGE UNIVERSITY.—At a congregation held on the 2nd inst., the degree of M.D. was conferred on Henry French Banham, St. John's College.

DR. ALFRED SANDERSON, Surgeon-Major, Madras Medical Establishment, has been placed on the Commission of the Peace for the county of Edinburgh.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination held by the above Institute on June 2nd and 3rd, six candidates presented themselves, and the Institute's certificate of competency as Local Surveyor was awarded to Samuel S. Grimley and to Arthur Whitcombe; and the Institute's certificate of competency as Inspector of Nuisances was awarded to John Tatem Cowderoy, to Joseph Rains, and to William Wilkinson.

DR. J. E. MILLER, lately Alderman of the East Ward of Londonderry, has, on severing his connexion with the corporation, received a testimonial from his former colleagues and fellow-citizens in the shape of a solid silver centre-piece. The presentation was accompanied by an address, signed by the Mayor and the Town Clerk, conveying in very flattering terms the sense of the members of the Town Council of Dr. Miller's worth.

A VERY flattering testimonial has been presented by the members of the Portland Lodge of the Nottingham Albion Order of Odd Fellows to their medical officer, Mr. E. J. O'Mullane, L.K.Q.C.P.I., &c. The testimonial consisted of an illuminated address, mounted in a gold frame, and expressive of the subscribers' high sense of the value of Mr. O'Mullane's professional services, and of the estimation in which they hold him as "a gentlemen, a scholar, and a philanthropist."

THE BRITISH ASSOCIATION.—The first general meeting of this Association is fixed for Wednesday evening, Aug. 31st, when Sir John Lubbock, M.P., will assume the presidency, and deliver an address. On Thursday evening a *soirée* will be held, and on the following Friday and Monday evenings addresses will be delivered by Professor Huxley and Dr. Spottiswoode, President of the Royal Society. On Tuesday another *soirée* will take place, and the concluding general meeting will be held on the Wednesday after. The Chemical Science section will be presided over by Professor A. W. Williamson. The Biology section will have as President Richard Owen; the Vice-Presidents being Professor W. H. Flower and Professor J. Burdon Sanderson; Professor Flower will preside over the department of Anthropology, and Professor Burdon Sanderson over that of Anatomy and Physiology.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the lates*

BARLOW, J., M.D., C.M., M.R.C.S.E., has been appointed Extra Surgeon to the Glasgow Royal Infirmary Dispensary.

BARNS, J. G., L.R.C.P.L., M.R.C.S.E., has been elected Assistant House-Surgeon to the Liverpool Dispensaries, vice P. O. Haynes, M.R.C.S.E., resigned.

COOPER, J. W., M.R.C.S.E., has been appointed Medical Officer of the Infirmary and Workhouse, St. George's-in-the-East, vice Belcher.

FISHER, W. W., M.A., has been appointed Public Analyst for the County of Oxford. Remuneration by fees.

GRUBB, P., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Warminster Urban Sanitary District.

HAMIL, R. J., M.R.C.S.E., has been appointed Assistant Medical Officer to the Infirmary and Workhouse, St. George's-in-the-East.

HITCHCOCK, Dr., has been appointed Medical Officer for the East District of the Gamrie Union, vice Collie, deceased.

KEMPE, C. M., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Shoreham Port and Urban Sanitary Districts.

MEESON, A., L.S.A.L., has been appointed Resident Medical Officer to the Workhouse of the Toxteth Union, vice M'Donnell, resigned.

NANCE, H. C., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Whitehaven and West Cumberland Infirmary, vice W. E. Hoyle, resigned.

PRICE, W. H., M.R.C.S.E., has been appointed Medical Officer for the Western District of the Corwen Union.

RICHARDSON, J. H. H., has been elected Resident Medical Officer to the Wandsworth Provident Dispensary.

SYSON, E. J., L.R.C P.Ed., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the St. Neots, Caxton, and Arrington Rural Sanitary District for one year.

WANKLYN, A. J., F.C.S., has been reappointed Public Analyst for the Borough of Peterborough.

WHITE, T. G., L. & M.K.Q.C.P.I., L.R.C.S.I., has been appointed Surgeon to the Colar Gold Mining District, Mysore, India.

WILLIAMS, W. R., F.R.C.S., L.R.C.P., has been appointed House-Surgeon to St. Peter's Hospital for Stone &c., vice W. Neale, M.B., M.R.C.S.E., whose term of office has expired.

WILLS, J. P., M.B., has been appointed Medical Officer to the Metropolitan Convalescent Institution's new Home at Bexhill, Sussex.

WOODCOCK, R. F., L.R.C.P.L. & M.R.C S.E., has been appointed an Honorary Medical Officer to the Royal Albert Edward Infirmary and Dispensary, Wigan.

Births, Marriages, and Deaths.

BIRTHS.

CHURCHILL.—On the 1st inst., at Cranley-gardens, South Kensington, the wife of Frederick Churchill, M.D., F.R.C.S., of a son.

CROOM.—On the 3rd inst., at 25, Charlotte-square, Edinburgh, the wife of Dr. Halliday Croom, of a daughter.

DAVISON.—On the 8th inst., at Langton House, Battle, Sussex, the wife of Rashell Davison, M.B., M.R.C.S E., of a son.

DE BRENT.—On the 1st inst., at Church House, Aveley, Essex, the wife of Mortimer de Brent, M.R.C.S.E., L.S.A.L., of a daughter.

POTTER.—On the 6th inst., at George-street, Hanover-square, the wife of John B. Potter, M.D., F.R.C.P., of a daughter.

MARRIAGES.

BROWN—THORBURN.—On the 6th inst., at John's-place, Leith, J. Graham Brown, M.D., M.R.C.P.E., to Jane Pasley Hay, daughter of the Rev. David Thorburn.

KEMP—HALAHAN.—On the 1st inst., at St. James's, Piccadilly, by the Rev. Dyer Tovey, John R. Kemp, L.R.C.P.L., M.R.C.S.E., to Harriet, eldest daughter of Peter Halahan, Esq., of South Kensington.

OGG—VINCENT.—On the 2nd inst., at St. Philip and St. James's Church, Whitton, Hounslow, Surgeon-Major G. S. W. Ogg, Madras Medical Service, to Clara, widow of J. H. Vincent, Esq., of Southampton.

READ—GIBBS.—On the 1st inst., at Waltham Abbey, Charles Read, F.R.C.S., of Upper Wimpole-street, to Ethel, second daughter of W. A. Gibbs, of Gilwell-park, Sewardstone.

REEVE—TODD.—On the 1st inst., at Hollington Church, near Hastings, by the Rev. — Adams, Henry Reeve, son of the late Henry Reeve, of Victoria-park, to Barbara, youngest daughter of John Waterloo Todd, of 301, Mile-end-road.

TURTON—RUGG.—On the 8th inst., at Hove Parish Church, by the Rev. T. Peacey, M.A., Vicar, James Turton, M.R.C.S.E., of Heckmondwicke, to Ellen Bradley, fourth daughter of Richard Rugg, F.R.C.S.E., of Lansdowne-place, Brighton.

WILKINS—MANNING.—On the 8th inst., at St. Mary's Church, Carisbrooke, Isle of Wight, by the Vicar, the Rev. E. B. James, M.A., Robert Bird, second son of Dr. Wilkins, of Newport, Isle of Wight, to Rosalie, only child of J. L. Manning, Esq., of Alvington Manor, Carisbrooke, Isle of Wight. No cards.

DEATHS.

BIRD.—On the 1st inst., at St. Leonard's-place, York, William Bird, M.D., aged 49.

BISHOP.—On the 5th inst., at Tonbridge, Kent, Henry Bishop, M.R.C.S.E., aged 49.

CLOSE.—On the 5th inst., at Sorrento, Italy, Percy Close, M.R.C.S.E., youngest son of John Close, Esq., of Dringhouses, York, aged 24.

DOUGLAS.—On the 13th February, at Port Chalmers, New Zealand, Margaret Louise, younger daughter of T. Kennedy Douglas, M.B., C.M., Tapanui, Otago, New Zealand, aged 10 months.

LANG.—On the 1st inst., at Lansdowne, Southport, Phebe, widow of John Lang, M.D.

SHEPHERD.—On the 4th inst., at Swansea, James Shepherd, M.R.C.S.E., L.S.A.L.

WHITE.—On the 29th ult., at Ferryhill, Aberdeen, Robert White, M.D., aged 61.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, June 13.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor Jonathan Hutchinson, "On the Laws of Inheritance in Relation to Disease."

Tuesday, June 14.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. J. Park Harrison: Exhibition of Danish and French Photographs.—Major-General A. Pitt-Rivers, "On the Discovery of Flint Implements in the Gravel of the Nile Valley, near Thebes."—Mr. Alfred Tylor, "On the Human Fossil at Nice."—Mr. Gerrard A. Kinahan, "On Sepulchral Remains at Rathdown, Co. Wicklow."—Mr. J. H. Madge, "On Notes on some Excavations made in Tumuli, near Copiapó, Chili, in June, 1880."—Mr. F. E. im Thurn, "On some Stone Implements from British Guiana."—Mr. G. Bertin, "On the Origin of the Semites."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8 P.M. Ballot.—8.30 P.M. Mr. Morrant Baker, "On a Case of Urticaria Tuberosa."—Mr. John Croft, "On Immediate Treatment of Fractures of the Leg by Plaster of Paris Splints."—Mr. C. T. Dent, "On the Pathology of Acute Periostitis."—Mr. Clement Lucas will show a Case of Aneurism by Anastomosis of the Face and Orbit, and a successful Case of Nephrectomy.

Wednesday, June 15.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor Jonathan Hutchinson, "On the Laws of Inheritance in Relation to Disease."

Thursday, June 16.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, June 17.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor Jonathan Hutchinson, "On the Laws of Inheritance in Relation to Disease."

Saturday, June 18.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

A NEW MEDICINAL FISH OIL.

THE oil of the oolachan or boulican (*thaleichthys*), a fish inhabiting the waters of British Columbia and Vancouver's Island in enormous quantities, is (says *The Colonies and India*) finding its way into the English markets as a substitute for the cod-liver oil. This fish is of so oleaginous a nature that it is dried and used as a candle by the natives of British Columbia, being known by the name of the "candle-fish." The oil has long been valued for its medicinal virtues among the native Indians, but has only lately been prepared in such a form as to compete with cod-liver oil, for which, however, it is said to be a valuable substitute.

W. T.—We regret we cannot comply with our correspondent's request.

Dr. Robert Bell.—We are unable to devote space to the subject at present.

Fiat Justitia.—The question should have been addressed to the Local Government Board.

Dr. A. Harbinson.—If microscopical sections are prepared and forwarded they will be examined.

CONCURRENT VARIOLA AND VACCINIA.

To the Editor of THE LANCET.

SIR,—I cannot think that "M.B.'s" "facts" by any means explain my case, and I cannot believe that it is good pathology either to regard the "invasion" of small-pox as coincident with constitutional symptoms, or to look upon the incubatory period as one of absolute quiescence.

The authority of Section 86 of the "Medical Digest" notwithstanding, I venture to assert that the concurrence of confluent small-pox with vaccinia is extremely rare.

My case reached the period of greatest intensity four days after the appearance of the eruption. There was enormous swelling of the head and neck, obliteration of features, blindness, severe sore-throat, and partial delirium, which after about thirty-six hours rapidly abated, and the man has made a good recovery. Thus the case much resembles that of Mr. Box. As, however, out of thirty-eight cases of small-pox I have had under my care in the last month, two of the confluent kind have shown this quick abatement, I do not think it should be hastily assumed that the concurrence of vaccinia was the cause. "O. H.'s" case was one of revaccination; the other two, aged thirteen and twenty-six, of vaccination in infancy.

I must, I fear, still subscribe myself, Sir, yours,

June 7th, 1881. IN PERPLEXITY.

ERUPTIONS FOLLOWING VACCINATION.

To the Editor of THE LANCET.

SIR,—I would be glad to know, through the medium of your journal, if vaccinators are unfortunate occasionally in having eruptions follow their vaccinations. I have had a few only, although I vaccinate some hundreds in the year. The other day I had a case with eruptions, and four other babies vaccinated with the same lymph are perfectly well. I believe that in those cases that "break out" there must be a predisposition to have some form of skin disease, and that the vaccination acts as an excitant. If vaccinators will please give their opinion and the percentage of cases that have occurred with them they will oblige.

I am, Sir, yours truly,

June 6th, 1881. T V

A FREE PICTURE GALLERY.

RECOGNISING as we do the wholesome influence upon the general public and especially upon the industrial classes, of facilities for the study of works of art, we are glad to notice the liberality of the managers of the United Art Gallery, New Bond-street, in opening their exhibition free on every Saturday evening during the month of June. On Whit Monday gratuitous admission was accorded to the rooms, which were visited, we understand, by over 2000 people.

THE NATIONAL VACCINE ESTABLISHMENT AND ITS LYMPH

To the Editor of THE LANCET.

SIR,—With reference to the article in your last issue, I wish to point to what seems to me to be a probable cause of the inefficiency of lymph supplied by the National Vaccine Establishment. Tubes sent to the National Vaccine Establishment by public vaccinators are submitted to an examination at the National Vaccine Establishment, and it is this examination I believe to be the great source of feeble lymph being stored by the National Vaccine Establishment, for if the lymph in a tube under examination is opaque, it is invariably rejected. Now, I have repeatedly noticed that, after carefully selecting and opening what are designated as "true Jennerian vesicles," and collecting lymph as it exudes from vesicles in half a dozen or more tubes, the lymph collected in the first two or three tubes is more opaque than the lymph collected in the remaining half-dozen or more tubes; and likewise, after selecting an arm with other than "true Jennerian vesicles"—viz., one having vesicles with well developed areolæ—that very often perfectly clear and transparent lymph will flow from them and in great quantity. I have recently collected and vaccinated with lymph of this description, and have utterly failed in both primary and revaccinations. I also find that vaccinations performed with the first lymph that flows on opening "true Jennerian vesicles" are most successful both as regards number of vesicles and the small amount of attendant inflammation.

I am, Sir, yours obediently,
Woolwich, June 7th, 1881. J. GASCOIGNE WEBB, M.R.C.S.

To the Editor of THE LANCET.

SIR,—As an impression seems to be abroad that the lymph supplied by the National Vaccine Institution is more or less inert, permit me to state that on the 10th inst. I had but two tubes of lymph (received from that institution) wherewith to revaccinate eighteen boys, and that of the eighteen revaccinated fourteen resulted in a perfect vaccine vesicle, and four in a modified one, showing that the virus "took" in every case. Everyone of these boys bore the mark of a previous vaccination.

My mode of proceeding was as follows:—My supply of lymph being so scanty, I blew out the contents of the two tubes on to a piece of glass, and added an equal quantity of water. I then scratched the arm with a lancet, but not so deeply as to draw blood, making the skin tense with my left hand. I then charged the lancet, and "dabbed" the diluted lymph well into the abrased surface, with the results above stated.

I have practised various modes of vaccination, but find this the most effectual. I am, Sir, your obedient servant,
P. KEELAN, Fleet Surgeon.
H.M.S. *Ganges*, Falmouth, May 26th, 1881.

To the Editor of THE LANCET.

SIR,—Until lately I should have been disposed to have joined in the outcry against the lymph supplied by the National Vaccine Establishment, but during the last twelve months I have been driven to seek supplies twice from that establishment, and on those occasions I adopted the plan of touching the point of my lancet with a wet sponge before charging it with lymph, and my success was all that could be desired.

I am, Sir, yours faithfully,
June 7th, 1881. A PUBLIC VACCINATOR OF FORTY YEARS' STANDING.

To the Editor of THE LANCET.

SIR,—I think we could help our London friends in the way of vaccine in their present emergency very considerably. If they would write at once to their country friends many could keep up a stock for a time; but as we cannot procure points in the country, let it be understood that they return uncharged points at once, as a neglect of this part cripples one's action. I am, Sir, yours truly,
Bocking, June 7th, 1881. THOS. TAYLOR.

To the Editor of THE LANCET.

SIR,—It is not often that I require vaccine matter. The week before last I wrote to the National Vaccination Establishment and received three tubes; with one of these I revaccinated a boy whose parents required it to be done. Nothing could be more satisfactory than the result of the use of the vaccine matter supplied.

I am, Sir, yours truly,
Marlborough College, June 6th, 1881. WALTER FERGUS, M.D.

To the Editor of THE LANCET.

SIR,—With reference to the correspondence on the lymph of the National Vaccine Establishment, I have to say I have been supplied on some twenty occasions during the last dozen years from that establishment, and have had only two failures.

I am, Sir, yours faithfully,
Brentwood, June 4th, 1881. J. R. WHITE, M.B.

*** This discussion must now cease.—ED. L.

THE FALLACY OF HOMŒOPATHY.

To the Editor of THE LANCET.

SIR,—In your leader of last week you seem to invite a reply to your arguments. Had you been as familiar with the literature of homœopathy as I am obliged to be, you would have been aware that your argument that though the medicine be selected according to the rule *similia similibus* its action is on the principle *contraria contrariis*, has been advanced over and over again by partisans of the homœopathic school, so that we may adopt it and yet remain convinced of the truth of our homœopathic therapeutic rule.

With the exception, I think, of opium and alcohol, all the examples you give of the apparently opposite action of large and small doses are untenable, for the conditions under which they so act are not alike. Thus you rightly state that a full dose of aconite "will produce the local and general symptoms of fever and inflammation," but you should have added "on the healthy;" and, again, you are correct in stating that a smaller dose will "reduce the local and general symptoms characteristic of the state called 'feverish' and 'inflammatory.'" But, as you observe, this opposite action of the small dose is in disease, not in health. The same remarks apply to your illustration of the opposite effects of nux vomica in large and small doses. I cannot say anything about your illustration of the aperient action of cathartics in large and their constipating effects in small doses; the word "cathartics" comprises such an immense number of medicines that this opposite action may be true of some of them, but not of others; every "cathartic," besides an aperient, having other actions differing from those of other medicines placed by your school in the same category. I know nothing of the sedative or constipative action of calomel in large doses, and you do not mention whether this is an absolute or only a relative action. We are quite willing to grant that "as far as the action of remedies is concerned homœopathy is a misnomer," and I do not know of anyone in the homœopathic school who has even plausibly contended for the homœopathic action of the drugs he homœopathically selects, unless perhaps Hahnemann himself in one of his early theories regarding the mode of action of remedies. The theory to which I allude was never accepted by any of his disciples, and was tacitly abandoned by Hahnemann himself.

Thus you observe, as "honest men we must confess that you are right, and that the homœopathy of our system concerns only the mode of selecting drugs, not their action." But this is what we have held all along; so now that you know this we expect you to have a more favourable opinion of us and our system than you have hitherto had.

But you say that should we take this ground (which we have always held), you will then have to show that homœopathy is untenable, "because the selection of a drug by an inverse process of induction from its supposed effects can never be a sure or safe guide to its use." You add, "the effects are not located in the drug!" But no one ever said they were; the drug is the cause of the effects it produces in the organism. Again you say, "the only rational way to try a drug is first in health and then in disease." Here, too, we are at one; only you do not say how the effects observed from the preliminary trial of the drug in health are to guide us in trying it in disease. Our "rule" says try it in those diseases whose symptoms resemble the effects of the drugs we have tried on the healthy. What better—what other—rule have you to offer? for it is impossible you can wish us to try a drug in all possible diseases after having carefully tried it on the healthy. The results of our trials of a drug in health must surely give us some clue to its application in disease; if not, what was the use of our painful trials of it in health?

I must join issue with you when you say "the homœopathist does not choose his drugs on the principle *similia similibus*," for we do endeavour to choose our drugs on this therapeutic rule; but we certainly do not abandon experience; in fact, the only thing we have to show the truth of our rule is experience, and it is a curious fact that one of Hahnemann's earliest essays in which he announced the homœopathic therapeutic rule bears the title of "The Medicine of Experience."

I heartily agree with you when you say "so far as the homœopathist is a practitioner of medicine at all, he must and does employ drugs on rational and common-sense principles," and my earnest hope is that the great body of the medical profession will speedily adopt our rational and common-sense principles, and thus will be effected that reconcilement of the two schools "on grounds welcome to both parties."

I am, Sir, your obedient servant,
London, May 23rd, 1881. R. E. DUDGEON.

To the Editor of THE LANCET.

SIR,—It is with much interest that I have read your leader on the "Fallacy of Homœopathy" in your last week's issue. Allow a "reputed homœopath" to say that it affords the alone instance in ordinary medical literature—perhaps with the exception of certain articles by Dr. Ross in the *Practitioner*—in which the subject receives sober and dignified treatment; and the suggestion with which your article closes—viz., that this "regrettable alienation and controversy" be done away with for ever, will strike a chord in the heart of every honest thinking medical practitioner.

With most of the subject matter of the article I thoroughly agree, and should have agreed at any time since I studied homœopathy. Most "thinking homœopaths" heartily acknowledge the law of similars to be a phenomenal, indicative, law only; they maintain vigorously the apparently opposite actions of large and small doses, and believe with you that these opposite effects do not lie in the dose, but in the different action of the system under different doses; and many of us hold in consequence that though our selection of remedies is by the law of similars, the curative action of the small dose is by the law of contraries (antipathic).

On these points, then, THE LANCET and most "thinking homœopaths" (to our great surprise and joy, I own) are at one. Our points of difference are, therefore, narrowed to this—"Is the selection of a drug by an inverse process of induction from its supposed effects a sure and safe guide to its use?" I answer that it most undoubtedly is so. As a matter of fact, it has historically been so over and over again. Aconite, nux vomica, ipecacuanha, opium, cathartic remedies which you have instanced in your article, were all used by "reputed homœopathists" in the diseased conditions you roughly name, because it was known that they produced similar effects in health, and this years—ay, a generation and a half—before they passed empirically into the ordinary practice of physic. When Ringer's experiments elicited the diaphoretic action of jaborandi, I at once began to use it in the night-sweats of phthisis. When the emetic properties of apomorphia were discovered "homœopaths" at once suggested it as useful in emesis. Moreover, it is the coarse, semi-poisonous effect of the large or middling dose that alone can be noticed by the physician in the healthy. The finer therapeutical action, so noticeable in disease—as, for instance, the "tonic action" of ipecacuanha in emesis—cannot be, or very seldom can be, from the very nature of the case, discovered in a healthy subject.

Look at it how you will, if you are to utilise in any great measure at all the pathogenetic effects of drugs on the healthy, it must be done by recognising the apparently opposing actions of small and large doses, and by giving the small dose where the large dose is homœopathically indicated. This is what I, for one, understand by homœopathy, and how, so far as in me lies, I endeavour to use it in practice.

One word more. If this is all the difference between us, is it worth while for a great and learned and dignified profession to keep up, as it has for so long done, its ban against a small if "thinking" minority? If I and the writer of your article are to prescribe the same thing in nearly the same dose in similar cases, is it worth while for him to excommunicate me because I arrive at my treatment by a consideration of the effects in health of larger doses, and he at his by a consideration of the effects in disease of smaller doses?—I am, Sir, yours faithfully,

HERBERT NANKIVELL, M.D. Edin.

Penmellyn, Bournemouth, May 23rd, 1881.

To the Editor of THE LANCET.

SIR,—As there are some important points in your leader of May 21st with which the majority of homœopaths, and I among the number, agree, I request a short space in your columns, as you say "we shall be curious to see how the homœopathists attempt to answer this objection." This "objection" is that "homœopathy is a misnomer, and involves a fallacy," inasmuch as, according to your correct description, the drug symptoms correspond with those of the disease when the drug is given in large doses only, whereas for curative purposes, as it is given in a small dose, it produces the opposite effect, or acts by *contraria contrariis*, and that therefore the "homœopathy of their system concerns only the mode of selecting drugs, and not their action."

I answer this "objection" by perfectly agreeing with you; but your suggestion of the really contrary action of "homœopathic" remedies is not novel. In "Fletcher's Pathology," published in 1842, we find the author speaking of homœopathic medicines and their theory of action, and saying "They cure, not by the stronger, but by the opposite impression which they make; so that homœopathic medicines, after all, operate on the antipathic principle." Again, Dr. Dudgeon, in his able lectures on "The Theory and Practice of Homœopathy," delivered in 1852 (p. 111), says, "Whilst this (the law of similia) expresses only the rule for the selection of the remedy, the actual curative process is rather *contraria contrariis*, for the impression we effect with our remedial agent is the opposite of the existing condition of the diseased part." And if you will consult our periodical literature since this date, and especially within the last ten years, you will find the same view is maintained by the majority of homœopaths. The law or aphorism *similia similibus curentur* is simply one for the selection of the remedy, and involves no theory of the actual *modus operandi* of it. Theories on this point have been numerous, beginning with Hahnemann himself, whose theory, it is well to notice, and those of all since him, simply endeavours to explain facts; but, whether right or wrong, this theory in no way alters the facts.

But it is quite another matter to say that because the actual *modus operandi* of the small dose in cure is contrary, not similar, to the disease, therefore "the homœopath does not give his drugs on homœopathic principles, and cannot claim it as homœopathic, because he employs it in doses which do not produce effects like, but widely unlike, the symptoms of the disease he seeks to cure." This is simply to play upon the word. A medicine which produces in full doses symptoms closely like those of a given disease, and at the same time is found to cure it in a small dose, whatever the theory of the action may be, is in the fullest sense homœopathic to the disease. The fact of this double relation of the drug to the disease was the thing that was recognised by Hahnemann and his followers when the name "homœopathy" was adopted to express the treatment of disease in accordance with this relation, and before any theory was mooted as to the *modus operandi* of the drug.

Some word must have been used and must still be used to express treatment in accordance with this drug and disease relation, and as not only was the similarity of the effects of the large dose to the disease the prominent feature brought into notice, but the actual guide for the choice of the remedy, so is such treatment properly and correctly styled homœopathic. I hope, therefore, that as since 1852 it has been admitted that the real action of the small dose of a medicine which is homœopathic to a case of disease is that of contraries, any play upon the word or the correctness of it as applied to the small or curative dose only will be abandoned, as beside the main point at issue.

Next, Sir, you state that this explanation of the action of the small dose "explains the reiterated assertion made by homœopathists, to the effect that remedies which they believe to act homœopathically are recommended by accredited authors in standard works on therapy. It must be so. All remedies lie open to the charge or claim of being "homœopathic," if the homœopathist may class them by the effects they produce when given in one dose, while he employs them in another dose, of which the effect is totally different, and nearly always opposite. This is quite correct, but we never claim that "accredited authors in standard works on therapy" adopt homœopathic treatment, unless we find them recommending the treatment of a disease by a smaller than the usual pharmacopœial dose of a remedy which in a full dose will produce in the healthy body a similar state of disease. You correctly state that the curative dose must be smaller than that which will induce the disease symptoms, and wherein (1) the drug chosen is one which has produced a similar state in a larger dose, and (2) it is given in a smaller dose than will aggravate, the treatment, I maintain, is homœopathic. How small the best dose is is merely a question of experience. The illustrations you adduce are amply sufficient; but, may I ask, how much nearer are you towards settling the question by saying "Now, how do nux vomica and its preparations act in small doses? Why, as tonics to the muscular system." In the same way the late Dr. Anstie, when reviewing in the "Practitioner" Ringer's first edition of his "Therapeutics," says of the action of drop doses of ipecacuanha wine in sickness, that "it is not homœopathy, but only shows that these small doses of ipecacuanha wine have tonic effect upon the vaso-motor nerves of the stomach." This may be very true, but as far as the real question at issue is concerned, it is merely throwing dust in the eyes. Is it not much better to men philosophical simply to admit the fact that these medicines cure in small doses symptoms similar to those they produce in large ones, and are undoubted examples of "homœopathically" acting remedies?

3. You state that "the selection of a drug by an inverse process of induction from its supposed effects can never be a sure or safe guide to its use." This is a question for experiment to settle. Homœopaths maintain that it is a sure and safe guide.

4. You say "it is unscientific to speak of a drug as producing 'effects' or 'symptoms' in the organisms. . . . . The effects are not located in the drug." Who ever said they were? Is not this also mere play on words?

5. "It follows that the only rational way to try a drug is first in health and then in disease." Precisely so; this is what Hahnemann did, but he and his followers confined their trials in disease to those cases where a similar train of symptoms was present to those produced by the drug on the healthy body.

6. "In short, it is not possible to predict the 'effect' which will follow its use until we have actually tested it first on a healthy and then on a morbid organism. The pretence of selecting remedies on any principle or theory of their mode of action in health alone is manifestly an affectation of the impossible." On this point all homœopaths join issue with you. Hahnemann "predicted" that camphor, veratrum, and cuprum would be the leading remedies in cholera. Arsenic was added to the list afterwards by "prediction."

We "predicted" that apomorphia, when first brought out as an emetic, would cure sickness, as ipecacuanha does, that chloral would cure urticaria, &c.; all which "predictions," and many others, proved true, as was anticipated. In fact, it is one of the strong points of the use of *similia* as our guide in selecting the remedy that we can thus "predict" its curative sphere as soon as we know its effects in health.

Nothing would rejoice the homœopaths more than to see a reconciliation of both "schools," "on grounds welcome to both parties in this regrettable alienation and controversy," to quote your own courteous words. Apologising for the length of this communication,

I am, Sir, yours, &c.,

Seymour-street, Portman-square, D. DYCE BROWN.
May 23rd, 1881.

DREAMS.

To the Editor of THE LANCET.

SIR,—I shall feel obliged by an answer from some of the very influential subscribers to your valuable paper to the following vital and important subject—viz., what, so far as is known, are the causes of dreams in general, their effect, and the best known method of avoiding them? I am, Sir, yours obediently,

King's Bench-walk, Temple, June 2nd, 1881. GABAM.

"HYPODERMIC INJECTION OF MORPHIA."

To the Editor of THE LANCET.

SIR,—Your correspondent, "J.," asks how best to ward off sickness following subcutaneous injection of morphia. I have extensively used the hypodermic method for twenty years. I would suggest nervine tonics both as food and drugs: as forming part of food malt extract and cod-liver oil; as medicine Fellows's syrup of hypophosphites, three times a day, given an hour before the injection; to persevere for some time. Electricity should also be tried to the painful part.

I am, Sir, yours faithfully,

Dinorwic Hospital, Llanberis, June 6th, 1881. T. HUGHES, M.D.

Medico.—Our correspondent is mistaken as to the relative rank of acting surgeons. The regulation on the subject is very clear. "The relative rank of medical officers in the volunteer force is determined by the same rule as that prescribed for medical officers of the army, except that acting surgeons always rank as lieutenants irrespective of their length of service. Surgeons appointed before October 1st, 1877, under previous regulations, will continue to hold the relative rank of major." We do not suppose that acting surgeons will get a step of rank on retirement, as no provision seems to be made for such a case.

Dr. Dale will see that we have gained the point in view, and the discussion will now cease. We are obliged for his letter.

Mr. W. B. Hunter's letter must stand over till next week.

So. Bong.—The law requires that the holder of an inspectorship of factories should be free from any personal interest in a factory or workshop he may be called upon to inspect.

"LICENSING BODIES AND THEIR DIPLOMAS."

To the Editor of THE LANCET.

SIR,—Many persons object to part with diplomas of deceased relatives If documents of the kind were sent to headquarters, accompanied by a certificate of death, there to have "Deceased" punched into their substance, no amount of after-manipulation could render them available for illegitimate purposes.—I am, Sir, yours faithfully,

June 6th, 1881. J. B. GILL, M.D.

VACCINATION REVIVED.

To the Editor of THE LANCET.

SIR,—On the 15th of last month I vaccinated a nurse who had been vaccinated on the right arm in four places without result four years ago. I vaccinated her on the left arm in four places, producing one fairly well marked secondary vaccine vesicle, with the usual inflammatory blush extending down the arm, and somewhat affecting the lymphatic glands of the axilla, chest, and neck.

Now occurred what was to me the extraordinary part of the case. The four places on her right arm where she had been vaccinated four years ago, without any apparent effect, became distinctly visible, exuded an appreciable amount of lymph, threw out a distinct areola, and became, in fact, tolerably characteristic of secondary vaccination. I can only account for the above facts by supposing that the vaccine virus inserted in these places four years ago had been revived and stimulated into action by the effects of the virus I inserted into the other arm on the 15th of last month. It seems to me that this affords a pretty strong proof of the capability of animal poisons to lie dormant, but perhaps a better explanation may be given.

I am, Sir, yours obediently,

F. A. J. SHEPHERD.

St. Olave's Union Infirmary, Rotherhithe, S.E.,
June 7th, 1881.

P.S.—I have thought of the possible bearing of this case on latent cases of hydrophobia. Is it possible that other diseases may exist for an indefinite period in a state of latency, and be called into action by their appropriate stimuli?

Messrs. J. & C. Lloyd & Co.—The controversy had better be confined to the journal of the Society in connexion with which the charge complained of was made.

F. R.—The L.R.C.P. qualification does not confer on the holder the right to style himself "Dr."

Mr. Crespi's letter arrived too late for insertion in our present number.

Mr. Eddowes (Stamford).—If the Licentiate of a College of Surgeons is admitted to be a surgeon it would be difficult to show that the Licentiate of a College of Physicians is not a physician. The possessor of such qualifications is a doctor in the vulgar sense of being a medical man, but not in the sense of being a graduate of a university, nor is he entitled to use the prefix "Dr."

Appetitus Rationi Pareat.—The appointment is legal.

Questioner should apply to the secretary, Mr. Blackett, 28, Green-street, Grosvenor-square, W.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

ON HOSPITALS:

THEIR MANAGEMENT, CONSTRUCTION, AND ARRANGEMENTS IN RELATION TO THE SUCCESSFUL TREATMENT OF DISEASE, WITH REMARKS ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS.

By FREDERIC J. MOUAT, M.D., F.R.C.S.,

FORMERLY PROFESSOR OF MEDICINE, CLINICAL MEDICINE, AND MEDICAL JURISPRUDENCE IN THE MEDICAL COLLEGE OF CALCUTTA, AND FIRST PHYSICIAN OF THE HOSPITAL ATTACHED TO THE COLLEGE; DEPUTY INSPECTOR-GENERAL OF HOSPITALS (RETIRED); VICE-PRESIDENT AND FOREIGN SECRETARY TO THE STATISTICAL SOCIETY OF LONDON, ETC.

II.—THE CONSTRUCTION AND ARRANGEMENTS OF HOSPITALS.

FOR more than a century past the subject of the construction of hospitals has attracted attention, and been discussed and re-discussed by a multitude of able men. Sometimes with scientific precision uninfluenced by personal feeling; often with anger and acrimony; and not unseldom with the profoundest sentiments of sympathy with the sick and suffering, and the most earnest desire to place them in the position best calculated to afford them the fairest chances of life, and restoration to health.

The labours of John Howard in this field are well known; but the first serious attempt to treat the subject with scientific accuracy was that of MM. Tenon and Bailly, when considering the grave defects of the old Hôtel Dieu, and the best means of remedying them. The classical work of the former laid the foundations of the system now being adopted, and is the most valuable contribution ever offered on the question. It is somewhat singular, that after the lapse of nearly a century, the question of the entire removal of the same Hôtel Dieu should again have given rise to prolonged discussions in the Academy of Medicine and the Surgical Society of Paris, and of the official commission appointed to consider and carry it into effect. The conclusions arrived at by the Société de Chirurgie have since guided the action of the most advanced reformers in this direction, as I shall endeavour to show further on.

The Crimean war, the contest between Prussia and Austria after the Schleswig-Holstein conflict, the great war of secession in the United States, and the Franco-German war, again strongly directed the attention of the public and of the profession to the best means of dealing with accidents, injuries, and disease in large bodies of men suddenly collected in overwhelming numbers, so as to avoid the fearful destruction of human life, inseparable from the old methods of managing such matters. The successful application of the arts of peace to the operations of war, was shown in the adoption of the principles so long ago advocated by Tenon.

The removal of St. Thomas's Hospital, the building of the Herbert and Netley Hospitals, the reconstruction of the Edinburgh and the building of the Western Glasgow Infirmaries, and the building of several new hospitals in different parts of England, attest the practical interest in the subject taken by ourselves.

The detailed, elaborate, and excellent report of Messrs. Bristowe and Holmes, with the remarks of the distinguished medical officer of the Privy Council, published as a parliamentary paper, with the writings of Miss Nightingale and Captain Douglas Galton, are still authorities of great value on this important and vexed question.

To attempt to take note of the ground covered by the various contentions in this century of conflict of opinion, would be as unprofitable, as it is impracticable, in a reasonable compass. It is, however, unnecessary. It will be sufficient for my purpose to state the conclusions arrived at, after prolonged discussion in Paris in 1864, inasmuch as they have in the main been observed in the latest hospitals built on the Continent of Europe, and in some of those recently constructed elsewhere, the chief exceptions being the costly failures of the new Hôtel Dieu and St. Thomas's Hospital, the former from a deliberate and intentional disregard of the true principles which have taken so long to establish, the latter from a singular, and not very intelligible misapplication of those principles. With us the deathblow to the aggregate or palatial plan was given by the late Sir James Simpson and Mr. Erichsen; for although the accuracy of the basis of the arguments of the former has been disputed, and the views of both have not obtained the same acceptance with us that they have done in other countries, their practical adoption in the most recent hospitals of Germany, France, and the United States, affords the best possible proof of their accuracy.

It was well said by Léon Lefort, one of the most competent authorities on the subject, that it is sometimes supposed that the question of hospital construction is an easy one, that architectural considerations should predominate, that hospitals should serve for the ornamentation of towns, that they are as easily planned as streets, and that the science of health or hygiene has little to do with them. He disputes the correctness of this view, inasmuch as the best authorities on health and disease have shown, that it demands the application of the most profound knowledge of medicine in all its branches, for its correct understanding.

The celebrated Philibert Delorme, the *protégé* of Catherine de' Medicis, and first architect of the Tuileries, now in ruins, in his "Traité Complète d'Architecture," published three centuries ago, foreshadowed the true principles involved in the construction of hospitals. "It would be better," he wrote, "for the architect to fail in ornamentation, such as columns and facettes, which all study most, than in those rules of nature which tend to the convenience, use, and profit of the inhabitants, and not the decoration, beauty, and enriching of buildings, which are only for the contentment of the eye, and bring no advantage to the *life and health of man.*"

Compelled by the exigency of time and space, I pass over other authorities, some of considerable eminence, to come to one who will, I believe, exercise a more permanent influence on the whole question of collective dwellings, than most of his predecessors or contemporaries. I refer to Monsieur C. Tollet, a French civil engineer and architect.

In 1876 M. Tollet presented to the Academy of Sciences in Paris, a memoir concerning the principles which should regulate the construction of collective buildings for both men and animals. In it he states that he was thus inspired by views formulated for more than a century by the most competent hygienists, views which have remained sterile by the united influence of routine and vanity, and by the irrational opinion that the potential voice was that of the constructor in a question of health, touching which the only profession competent to deal thoroughly with it was scarcely considered, and when consulted, disregarded.

M. Tollet has applied his system successfully to barracks, schools, and hospitals. That system, which bears his name, is one of single-storied pavilions, raised on plinths and built in separate blocks on a peculiar form of construction, which, in my opinion, unites in the greatest degree the best sanitary conditions, with the most moderate cost, and the greatest permanent retention of healthy attributes. I shall refer more at length to them when I come to the description of the St. Eloi Hospital at Montpellier, and other institutions of a like character, constructed, or in progress, by him.

I shall not attempt to discuss the difficult and still undetermined problems connected with the causes of the vitiation of the air of a hospital, [together with the conditions under which septicæmia and blood-poisoning occur in wounds, and in some constitutional diseases. The existence of such influences cannot be denied. Whether they be due to putrefactive fermentation, the development of germs and living organisms, or any more subtle and less easily detected general agency, is comparatively of little importance in the determination of the question under consideration. The end to be sought is the best means of depriving these agencies of their power of mischief; and this is now admitted to be by placing all institutions in which many persons are congregated under the same roof, whether in health or in disease, in the best possible state to secure the utmost attainable purity of all the essentials of health and life, such as air, soil, water, and the agencies which affect an individual, or may from him extend to other persons, and ultimately infect whole communities. Hence I shall reproduce, *in extenso*, the conclusions arrived at in Paris, for reasons already stated; and after considering the leading features connected with hospital construction, briefly describe such of the most recent, as appear to be best fitted to fulfil their purposes.

The conclusions of the Surgical Society of Paris, after ten prolonged sittings, were as follows:—

1. A hospital should be placed in an open space, upon a dry soil, with an inclined surface. This space should be large. A superficial area of thirty square metres (about thirty-five square yards) for each sick person is the minimum space that should be allowed, and this should be increased as much as possible, and should be augmented progressively with the increase in the number of sick.

2. The air of a hospital will be pure in proportion to its distance from thickly populated places. In the centre of cities hospitals for urgent cases alone, which are necessarily restricted in numbers, and for clinical purposes, should be retained. This measure of health will be at the same time one of economy, as it will allow large towns like Paris, to instal their hospitals on large areas at less cost.

3. Good hygienic conditions are easy to obtain in hospitals of from 200 to 250 sick. These conditions are impossible to obtain, in large towns, if double the amount of these figures is exceeded. Within these limits of numbers, the expense for all purposes, is not in excess of that of hospitals containing larger numbers.

4. The constituents of the atmosphere intermingle chiefly in a horizontal direction; hence the necessity of combating, by increased space, the effects of contact, and of the proximity which constitutes crowding, and the influence of which is communicated from patient to patient, ward to ward, and from one building to another.

5. To strive successfully against contagious influences not only needs an increase of the cubic space allowed to each sick person, but in addition, and above all, demands an increase of superficial area, which is at present insufficient in all our civil hospitals. For similar reasons the multiplication of stories is contra-indicated, as each of them generates a more or less vitiated atmosphere. From a rigorous hygienic stand-point the superposition of stories should be limited to two.

6. It is illusory to believe that a large cubical capacity in wards can replace an absence of external space and aeration, or to suppose that an abundant artificial ventilation can supply the place of either of those conditions. Nothing can compensate for the insufficiency or absence of natural aeration.

7. Buildings completely isolated, and all having the same aspect, freely exposed to light, and to the action of wind and rain, should be placed in a single, or in parallel lines, at intervals of from 80 to 100 metres (rather more than from 85 to 109 yards), so as to secure effective separation and external aeration.

8. Small wards of from fifteen to twenty beds are easy to superintend with care. In them the mutual discomfort of patients, and the chances of direct contagion, are diminished, and the rapid removal of all impurities is increased. They are preferable for the ordinary care of the sick, and do not affect prejudicially the special arrangements required for certain classes of disease, which need more space and the isolation of separate rooms.

9. The furniture of wards should interpose no obstacle to the free circulation of air. Bed curtains should be suppressed whenever it is considered necessary.

10. Wards should be separated by partitions, or rooms devoted to common service. One of them should be used as a day and dining-room for the benefit of all patients able to get up, and thus cause a daily incomplete emptying of the sick-room.

11. The periodical and regular evacuation of all sick wards, and their complete rest for months at a time, have produced such good effects in the military hospitals of France, and in the hospitals of other countries, as to be deserving of general adoption, which is a pressing necessity in times of epidemics.

12. Arrangements should be made to secure that all odorous and infectious matters, dejections, dressings, water used in cleansing, &c., should be rapidly destroyed or removed, and never be allowed to remain within or near the rooms occupied by the sick, or be permitted to cause any perceptible smell.

13. The central administration of the hospitals should be supplemented and assisted by a permanent consulting [advising] committee of health, holding periodical meetings. This committee should consist of physicians, surgeons, administrators, architects, and engineers, with power to call into council all the heads of hospitals, who are not members of the commission. The periodical meetings of the physicians, surgeons, and administrators of each hospital could furnish valuable advice to the central administration, to enable it to deal efficiently with all measures of progress."

Bearing these conclusions in mind, and knowing that, although susceptible of modification in some circumstances, they were based on a careful examination of the hospital systems of all countries at that time, and of our own in particular, I shall now proceed to consider the chief points which require examination, in any proposal for the building of the hospitals of the future.

These are (*a*) site and surroundings, (*b*) ventilation and warming, (*c*) water-supply, (*d*) the dimensions and distribution of buildings and wards, (*e*) size of hospitals, together with (*f*) furnishing and fitting.

(*a*) SITE AND SURROUNDINGS.

An ideal site for a hospital would be where the conditions of soil, subsoil, drainage, water-supply, and all surroundings were most free from local causes of impurity, and where there were fewest buildings and habitations to exclude or intercept air and light, or to be themselves active agents in the creation of causes of unhealthiness, such as factories, workshops, &c.

Sufficient practical experience and knowledge of the subject have been acquired to show that gravel and sand are more likely to be healthy than clay or any impermeable medium, which needs costly artificial contrivances to get rid of surface moisture and soluble impurities; that a hillside would in most, but not in all, circumstances be preferable to the base of a hill; that an elevated plateau or plain would, in temperate climates, be more advantageous than a bottom or valley, and so on.

But the necessities of the times in which we live, particularly in great cities and centres of industry, compel us to select, not that which is best in itself, but what is procurable at least cost, and the most accessible proximity to those who need it.

In London, for example, most of the older hospitals, which are now in densely crowded, or in unhealthy localities, were, when they were originally built, either in open fields, or so far removed from buildings of all kinds as to be free from most of the reproaches which now attach to them. Each recurring census return in Europe and in the United States shows with what startling rapidity manufacturing and other industrial towns and cities are expanding, and how quickly the centres of population in them are shifting. A glance at the Map which will accompany this paper will bring out in startling relief this fact as respects London. The census of 1871 gave it a population of 3,254,260 inhabitants, occupying an area of 125 square miles, in which the density of the population of the whole area was forty persons to an acre, and in its most crowded and least healthy localities range from 205 per acre in Whitechapel, to 325 per acre in St. Anne's, Soho. The census of 1881 has somewhat changed these figures, as I shall show hereafter. Now, Switzerland, with a population of 3,000,000, is spread over 15,980 square miles; Sweden, with a little more than four and a half millions, occupies 171,000 square miles; Holland, with about four millions, 12,730 square miles; and Denmark, with scarcely half the population of London, 14,760 square miles.

In addition to this extreme pressure of population upon space and the means of subsistence, the Map indicates the present provision of all kinds in the metropolis for sickness in all its forms, and how very unequally it is now distributed, as I shall endeavour to explain when treating of the organisation of its medical relief. The Map will appear in the issue of July the 16th. The same fact is witnessed, although in a diminished degree, in the sixteen towns of the United Kingdom which have a population of more than 100,000, and in the half dozen others which have probably by this time reached that number. This condition must be carefully borne in mind in all discussions on the relative merits of town and country sites, as proper places for hospitals for the use of town populations.

Wherever practicable, general hospitals should undoubtedly be placed in the outskirts of towns, as near as possible to the bulk of the population who require to resort to them; and all convalescent hospitals, imbecile asylums, hospitals for incurables, and similar institutions, should invariably be placed well clear of the town. But, hospitals attached to schools of medicine, and those which are intended for accidents, injuries, and acute cases which will not bear distant carriage, must still be in towns; hence their construction and arrangements should be so managed, as to minimise the evils inseparable from their position.

Every hospital, wherever placed, should be surrounded by a zone of aeration, unencumbered with buildings or any other cause of obstruction of light and air, to a distance of at least double the height of the buildings.

The interspaces, which should be found in all hospitals in town or country, should not be paved or concreted yards shut in by buildings, but open cultivated gardens, accessible to the convalescent, with shelter from the weather, so as to enable them to be as much in the open air as possible, whenever it is prudent or proper for them to be out of doors.

The aspect of a site, which will determine that of the buildings, should, wherever there is a choice in the matter, be such as to command the greatest amount of sunlight at all seasons. The duration, force, and other conditions of the prevailing winds should also be closely studied, as they now are in France and Germany, and the greatest care should be taken not to place hospitals where those winds blow over parts of country unhealthy, from whatever cause, natural or artificial.

The natural drainage and watershed of the locality should also be noted, together with its geological formation, where there is any choice of position.

(*b*) VENTILATION AND WARMING.

Some authorities seem to think that the healthiness, or otherwise, of hospitals is more a question of ventilation than of any other condition—that, so long as you give to each occupant of a sick-bed an adequate amount of space, cubical and superficial, and renew the atmosphere in which he lives and breathes, to such extent as to remove with sufficient frequency, all obvious and perceptible causes of impurity, without making this admission of itself a source of danger or annoyance—it matters little how many you place in each ward, to what extent you pile story upon story, or whether your hospital be placed in town or country. Some, again, appear to be satisfied that artificial systems of ventilation are of little or no use, and that what is termed natural ventilation is the only sound and efficient means of procuring a sufficient current of pure air, to counteract the unavoidably unwholesome influences of a sick ward. Others believe that dilution of the septic poison is sufficient to rob it of its power of mischief, provided it be carried to a sufficient extent.

I take leave to differ somewhat from all these views. Although not susceptible of strict mathematical proof from any statistical data at our command, there is an abundance of evidence on record, of an adequately exact nature, as regards prisons, barracks, factories, schools, and other institutions in which large numbers of human beings are congregated under one roof, to prove that their healthiness, or the reverse, bears a direct and definite ratio to the numbers aggregated upon a given surface, each having a sufficiency of air for healthy respiration in ordinary circumstances. So true is this, that in many examples known to me personally, in India and elsewhere, a hygeiometric scale of their salubrity might almost have been constructed, based upon the increase or decrease of the number of persons contained in them, all other conditions remaining unchanged.

It is tolerably certain that any one person can bear his own exhalations with comparative impunity, but, that he is liable to be poisoned by those of his neighbours, in an increasing ratio proportionate to their number. To such an extent is this correct, that if it were possible to place every sick or wounded person in a separate cell, and isolate him strictly from all others, the extension of all infectious diseases dependent upon a specific contagium, and all the ordinary forms of septicæmia, might be checked, and possibly extinguished.

The beneficial influence of such separation, was remarkably illustrated by an involuntary experiment performed in one of the prisons under my supervision in Bengal. Towards the end of the Orissa famine, a large number of half-starved, sickly men were sent to a district gaol, on account of certain grain robberies of which they were convicted. When that prison became dangerously overcrowded, they were transferred to another prison in a different district, which had spare room. The majority of these prisoners were placed in fairly ventilated wards, with ample room for each, according to the standard measurement allowed. About 120, however, for whom there was no spare room elsewhere, were put in as many separate cells, having 480 cubic feet of space each, and practically without ventilation, for, although they had open grated iron doors, they were situated in long corridors at right angles to the prevailing winds. A considerable number of the former died from different diseases, but chiefly from diarrhœa; while there was not a single casualty among the latter, who were said to have been the sickliest of the lot on admission, and who were on this account placed in the cells, which had long been known as the healthiest part of the prison in question.

A remarkable paper has recently been published in the *Annales d'Hygiène et de Médecine Légale*,[1] by Dr. Layet, Professor in the Faculty of Medicine at Bordeaux, on what he terms "the co-efficients of aeration, or the renewal of air necessary to prevent the effects of overcrowding in inhabited spaces." The professor contends that the quantity of air to be renewed for a person breathing in a space of 20 cubic metres differs from that required for the same person breathing in a space of 100 cubic metres. In the same manner if three, four, five, or six persons breathe in the same space, the figure of ventilation would not be the same, as if each of them breathed in the whole extent of this space. There is, therefore, no uniform, unvarying figure of ventilation, without reference to the size of the room, and the number of persons breathing in it. He has accordingly prepared a table of the co-efficients of aeration, to show at once the amount of air required to be renewed, in the different conditions of space and number. This is of importance where large numbers of people are assembled in a given space, and shows the considerable amount of air needed for renewal in such circumstances—a fact in harmony with the necessity at all times to counteract the ill effects of overcrowding. The professor has been good enough to send me his table, and the question has been discussed at a recent meeting of the Society of Public and Professional Hygiene in Paris, where it was objected that the method was defective in taking note only of the amount of carbonic acid and aqueous vapour present in an atmosphere breathed by many persons, whereas it is the presence of organic matters, that is really most injurious in such circumstances. True as this may be, the impurity caused by carbonic acid is a factor of sufficient importance to be able to determine in all circumstances, for it is chiefly upon this, that most of the practical rules adopted in ventilation are based, and upon it is founded the doctrine of the amount of cubic feet of air necessary for healthy respiration in all circumstances. Professor Tyndall's lecture on dust, and the labours of Pasteur and others on the nature of organic impurities, are gradually throwing a flood of light upon the whole question, and prove that the fewer the number of sick persons collected in a given space, however perfect the ventilation and other physical conditions, the better, and the more likely they are to escape the consequences of the particular vitiation of the atmosphere which causes blood-poisoning in most of its forms.

The problem, then, to be solved in all questions of ventilation is somewhat complex; hence the difficulty of dealing with it in such manner as to establish a general law applicable to all places and circumstances, as well as to all seasons and climates. From this cause, doubtless, arise the very different plans recommended by the highest authorities, engineering and medical.

The conditions to be secured are the utmost purity of air obtainable; as uniform a temperature as is found to be consistent with the maintenance of health at different seasons, and as rapid a renewal consistent with the above conditions, as will secure that as little vitiated air as possible, shall enter the lungs in each act of respiration. Physiology and chemistry have dealt decisively with the first two factors; and pathology is still engaged in determining what amount and kind of organic impurity are prejudicial to persons in health and injurious in disease, not only in relation to the individual, but to his becoming in turn a focus of infection to others; for it is in this manner that zymotic diseases arise and extend.

The measure of the purity of the atmosphere surrounding a building of any kind, will be that of the air finding its way into it, and its temperature will stand in very much the same relation. Hence the necessity of artificial contrivances to regulate it, in the extremes of heat and cold. But, in so mild and equable a climate as ours, expensive and complex contrivances for artificial ventilation do not appear to me to be needed, as they are in the hospitals of the northern parts of the United States, and in Central and Northern Europe.

All mechanical arrangements for ventilation should include warming, as a measure of economy as well as of comfort. Not only does the air of a sick ward need to be pure and of uniform temperature, but the floors ought equally to be warmed as they were in old Roman buildings and are in China. There are many ingenious and efficient contrivances for effecting this.

---

[1] No. 25, 4me Série, Jan. 1881.

The union, then, of natural and artificial ventilation, the former by means of sash windows, Tobin's tubes, and a multiplicity of simple means of admitting and removing air, the latter by open fires, acting as ventilating shafts, supplemented by the moderate and judicious use of warm water coils, will usually accomplish all that is desired.

To attempt to enumerate the infinite mechanical devices by which all this can be accomplished, is impossible. They may safely be left to the architect and the engineer, for whose guidance there is an abundant literature on the subject, both as to the end to be attained, and the means of securing it.

A point generally disregarded in all discussions on the subject of ventilation, is the purification of the air itself in sick rooms, which constantly contain the elements of their own corruption. These septic agencies may be diluted, and, to a certain extent, removed, by constant and rapid renewal of the hospital atmosphere; but they have a tendency to attach themselves to walls, bedding, &c., and their entire removal is a matter of much importance—so subtle is their action, so difficult their detection, and so imperfect our knowledge of the exact mode of their operation.

The Hindus of every part of India with which I am acquainted have from time immemorial possessed a means of purifying the atmosphere of their rooms and huts, by spreading a light coating of a mixture of earth, containing organic matters, on their walls and floors, which enables them to dispense, to a considerable degree, with ordinary ventilation. The process is called "leoping," and is usually performed by the women of the household. With a view to submit this proceeding to a practical test, I had four cells in the Presidency gaol of Calcutta, each containing 480 cubic feet of air and practically unventilated, carefully prepared. Two of them were limewashed throughout, and the two others "leoped." I had four healthy prisoners locked up in them at night, one in each cell. On opening the cells next morning, the two which were limewashed were stuffy and offensive, redolent of the peculiar animal odour exhaled by native prisoners in such circumstances. The two others were as fresh and as pure, as if no one had slept in them. This led me, as head of the prison department, to direct the application of the principle generally in all the gaols under my administrative control, so far as it was susceptible of direct application to walls, floors, and earthen beds. I also employed charcoal extensively for the same purpose, the purification of the air of prison wards from animal exhalations, and, I had reason to believe, with success. This seems to me to be deserving of careful trial in Europe.

In crowded cities, and in all positions in which the external air is likely to be contaminated by organic matters and malarious emanations, in winter especially, it might be subjected to a certain appreciable amount of purification by being passed through cotton-wool or charcoal.

Some writers have recommended that the walls of all masonry hospitals should be porous, to admit of the penetration of air at all times. This would, however, be attended with the grave disadvantage of their intercepting and retaining septic poisons. Masonry walls should therefore, I am of opinion, not only be absolutely impenetrable, but be coated with some hardened substance capable of being thoroughly cleansed without injury, whenever such a proceeding is desirable or necessary.

In some great hospitals, in addition to the effete air of the buildings generally, that of all waterclosets, sinks, and fireplaces, and all other sources of noxious exhalations, are passed through a great central ventilating shaft, represented by a tall, towering chimney. This does not appear to me to be a safe proceeding, and it may possibly explain the cause of the origin of the sickness, which is said to find its way into houses situated in the immediate vicinity of some of the great hospitals in Paris.

I have dwelt thus at length upon the subject of ventilation because, as I have already mentioned, some eminent authorities regard the whole matter of the unhealthiness or otherwise of hospitals to be mainly a question of this character. Hence also the coining of the barbarous term "hospitalism," which has led to much of the "logomachy" and differences of opinion which have arisen on the hospital question.

The French term "*malaria nosocomiale*" is both more correct and expressive, and if it could be condensed into a single word, such as "nosocom-aër," would be preferable to Sir James Simpson's invention, which is liable to considerable misapprehension, and includes other conditions which have no real connexion with the atmosphere of hospitals.

I assume that the best adjunct of all schemes of ventilation—scrupulous cleanliness—is observed, as it undeniably is in every well-regulated hospital in this country, particularly since the introduction of a higher class of nurses, for it is upon their intelligent and incessant care and attention, that the absence of all noxious agencies from impurities of any kind, of person, place, or appliances, is dependent. Associated with the purity of person and place is that of the disinfection and cleansing of all clothing and bedding, and the immediate destruction of all dressings &c., for which, as a rule, due and proper provision is or requires to be made.

(c) WATER-SUPPLY AND DRAINAGE.

The question of water-supply is one of the greatest importance in relation to the healthiness of hospitals, for if soluble impurities be dangerous to persons in health, their ingestion into the systems of the sick is still more injurious, from their diminished power of resisting disease. The great attention now paid to the subject, and the improved supply and distribution in all our larger towns, secure an abundant, and it rests with the hospital authorities to make it a wholesome, allowance. When hard it should be rendered soft by the Porter-Clark process, and the supply should be constant and practically unlimited, for at least double the quantity needed for the healthy is required for the sick.

Connected with water-supply is that of baths, and in this respect the French and German hospitals are, as a rule, much better furnished than our own. Every large hospital should have a complete system of baths for cleansing and therapeutic use, such as are now found in the University College Hospital of London; and all smaller institutions throughout the country, should be supplied with both fixed and movable baths.

Should the water-supply in country places be obtained from wells, or from storing of rain water, the greatest attention to its purity should be paid. The drainage in towns must be connected with the general drainage of the locality, and exceptional care be taken for the disconnexion of the drains and pipes of all kinds with the wards, by means which are now well known to all architects and engineers. To cause the ventilation of closets, sinks, and lavatories to be connected with great chimneys in crowded localities I hold to be erroneous, and likely to be mischievous, as they are now believed to be. When hospitals of any kind or class are isolated, and unconnected with any general system of drainage, all excretory matters should be strictly dealt with on one of the dry systems in use, and on no account should connexion with cesspools or tanks, or any scheme of sewage utilisation with water, be allowed, unless all such matters are previously disinfected. The more carefully they are deodorised, and, if necessary, as in typhoid dejections, disinfected, the less liable they will be to prove injurious before they are returned to the great natural purifier—the earth—aided by rapid vegetation.

In the construction of all hospitals proper provision for the above purposes should never be neglected, or sacrificed to any false economy, as too often obtains at present.

(To be continued.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.—During the year ending April 5th, 14 candidates were admitted to the Fellowship, 103 received the surgical licence of the College, and 10 the diploma in midwifery. Of the candidates for the Junior Class Examination 94 were rejected, and 40 at the Final Examination. The diploma in dental surgery was conferred on 111 candidates. Among the donations to the Museum may be mentioned that of Mr. Allen, which comprised a valuable collection of forty-eight objects, principally illustrative of the ethnology and natural history of South-west Africa; and a collection of specimens and photographs from Mr. Hillis, on the subject of leprosy. A sum of £25 has been contributed by the College towards the fund now being raised to defray the expenses of the proposed International Medical Congress.

THE PATHOLOGY AND TREATMENT OF DIARRHŒA IN PHTHISIS.

BY C. THEODORE WILLIAMS, M.A., M.D., &c.,
PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

(Concluded from p. 946.)

Clinical symptoms.—When ulceration is proceeding on a large scale in the intestines the patient complains of thirst and anorexia, the pulse is quick, and there is generally great prostration; the tongue passes from furred through various stages: first it is red at the edges, and furred in the centre; then red all over and glazed; then red with a brown streak in the centre; and, lastly, aphtha appears on it. The diarrhœa is remarkable for its persistency; the motions, especially towards the end of life, are very frequent—sometimes twenty in the twenty-four hours, but this is not always the case, and there may be only three or four daily, the characteristic feature being their steady persistency. They may be checked by treatment, but directly this is omitted, and often in spite of its action, the symptom returns; the stools themselves are very loose and ochrey-coloured, often tinged with blood, and towards the end of life contain small sloughs from the large intestine. They are exceedingly fetid, and the patient appears much exhausted after each action.

The aspect in these advanced cases is well-marked. Owing to the terrible emaciation the face is drawn, the malar bones appear prominent, a hectic spot is generally seen on each cheek, and the expression of the countenance is that of pain, and pain there generally is in the region of the ulceration, or else in the centre of the abdomen. Tenderness is generally to be found if carefully sought for; this of course varies in different cases. The right iliac fossa is the common seat of it in many, and especially in early, instances; but later on it may be detected in the right lumbar, right hypochondriac, epigastric, left hypochondriac, left lumbar and left iliac regions, showing clearly that the whole of the colon and sigmoid flexure are involved as well as the cæcum and lower ileum. Often, too, the detection is rendered more easy by the bowel being distended by flatus. The sigmoid flexure is, in my experience, as often the seat of ulceration as the cæcum, and I have frequently detected this during life, and verified it after death. The wasting arising from the diarrhœa is much greater than in ordinary pulmonary phthisis, and a few days of its persistence will reduce a consumptive, who has previously been gaining flesh, by several pounds.

The question arises, In what part of the intestinal canal does ulceration commence? The experience of post-mortems rather indicates that it commences in the small intestine near the ileo-cæcal valve; but how comes it then that we usually find the process more extensive and advanced in the large intestine? which will, I think, be generally admitted. The answer is to be found in (1) the long retention of the contents of the large intestine, (2) in the disengagement of foul gases in this region, and (3) in the enormous variations in calibre to which this part of the intestine is subject, all of which circumstances favour the spread of destructive or ulcerative inflammation, if once set up. Ulcers in the large intestine may be considered to be placed under most unfavourable conditions for healing.

The temperature varies according to the amount of the ulceration, provided there are no special exciting phenomena in the pulmonary or other lesions. Where the amount of ulceration is small and not advanced in stage, the temperature is not materially affected, as will be shown presently (Case 4); where, however, it is extensive, involving both small and large intestines, there is generally marked pyrexia, often alternated by great collapse. The chief feature, however, is its fitfulness; for one day at 11 o'clock the record may be 97° F., and on the following day, at the same hour, it may show 103° F.; these cases being the least of all amenable to the laws governing the pyrexia of phthisis. It is possible, however, to have extensive ulceration without any diarrhœa, for Dr. Douglas Powell gives a case in the Pathological Transactions, Vol. xix., where ulcers an inch and a half long were discovered in the ileum, and during life the patient had no diarrhœa. Dr. Pollock also mentions some exceptional cases of this sort.

Let us now take two instances of the influence of ulceration on temperature.

CASE 4.—Emma K——, aged twenty-nine, married, was admitted into the Brompton Hospital, Oct. 5th, 1875, with a history of cough and expectoration for one year, and of emaciation and night sweats for nine months. On admission she was much emaciated. Cough very troublesome; expectoration abundant. Yellow tongue, furred. Bowels costive. Weight 8 st. 5 lb. The physical signs were: crepitation sounds over the whole right lung, with dulness over the lower third; tubular sounds audible in the scapular region. During the first three weeks of her stay this patient improved, and gained 2 lb., but at the beginning of November diarrhœa came on, which persisted up to her death on Dec. 17th, the physical signs indicating that cavities had formed in both lungs. The temperature was taken five times a day from Nov. 26th to Dec. 16th, a period of three weeks, and only on five occasions did it reach or exceed 100° F. The following are the averages:—At 8 A.M. 98·2° F.; 11 A.M. 97·9° F.; 2 P.M. 98·5° F.; 5 P.M. 98·8° F.; 8 P.M. 99° F. Maximum, 100·6° F.; minimum, 96° F.

The diarrhœa varied in amount from three to six stools a day, and did not appear to be greatly influenced by treatment, which consisted of astringents applied by mouth and rectum. The patient died Dec. 17th.

Autopsy, twenty-four hours after death.—Lungs: Right had apex adherent, and a large cavity in the upper lobe. The rest of the lung was riddled with vomicæ containing purulent matter. In the middle of the lower lobe was a small well-defined band of miliary tubercle. The left lung contained several small cavities full of purulent matter, and a large quantity of transparent miliary tubercle of recent formation. The small intestine for the distance of three feet above the ileo-cæcal valve was very much congested. A small ulcer existed a few inches above the valve, and several small ones in the cæcum. Here some miliary tubercle was also seen. The liver and kidneys were fatty, and the other organs healthy.

Remarks.—This case shows convincingly two things: 1st, that a small amount of ulceration need not cause pyrexia; 2nd, that tubercle may form in more than one organ, without giving rise to any marked rise of temperature, and in fact with a persistence of subnormal records. There is no doubt that in this case acute tuberculisation as well as suppurative processes were proceeding in the lungs, and tuberculisation in the intestines, but they only served to depress the temperature, and not to raise it. The next case shows the effects of extensive ulceration on the temperature.

CASE 5.—Herbert N. M——, aged nineteen, a clerk, was admitted into the Brompton Hospital on Dec. 3rd, 1878. His father and mother died of consumption; he had suffered from cough and yellow expectoration, loss of flesh, and strength for two years. For the last ten months he had had continuous diarrhœa, accompanied by some pain in the epigastrium, after food. Had night sweats for three months. At present cough troublesome, expectoration abundant and muco-purulent, tongue furred, bowels open two or three times daily, appetite poor; urine acid, containing no albumen or sugar, sp. gr. 1035; weight 6 st. 4 lb. Physical signs: Flattening under both clavicles, dulness and crepitation above the right scapula, and tubular sounds in the first interspace. The diarrhœa persisted, in spite of a variety of astringents and diet having been tried, and on the 25th of January, 1879, well-marked tenderness was noted in the umbilical region. Cavernous sounds were audible at each apex, with crepitation in the lower left lung. The tongue had become red at the edges; the number of stools varied from two to four daily, and were loose and ochrey. On the 30th there was much tenderness in the lower portion of the abdomen, most marked in the left iliac fossa in the region of the sigmoid flexure, and to a less degree in the right iliac fossa. There was still some tenderness, quite separate from the rest, in the umbilical region. From these signs and the persistent diarrhœa I diagnosed ulceration of the cæcum and large intestine, most marked in the sigmoid flexure, with enlargement of the mesenteric glands from secondary absorption. The patient gradually wasted away under the influence of the pulmonary and intestinal lesions, and sank on February 7th.

The temperature was carefully taken five times a day during the last fortnight of his life, and the chart showed records nearly normal in the mornings, with a persistent pyrexia after 2 P.M. The highest recorded was 103·8° F. This chart, however, proves, as Lebert has shown in other cases, the fitfulness of the temperature in intestinal ulceration. There are several records of 101·5° F. at 8 A.M., once followed by a fall at 11 A.M., and a second rise at 2 P.M. During the last day of the patient's life the temperature fell from 102° F. to 96·8° F., indicating collapse of the vital powers. The following are the averages: At 8 A.M. 99° F.; at 11 A.M. 99·9° F.; at 2 P.M. 100° F.; at 5 P.M. 101° F.; at 8 P.M. 101·1° F. Maximum, 103·8° F.; minimum, 96·8° F.

Autopsy, on the following day.—Lungs: The right had pleura adherent, and contained a large cavity at the apex, surrounded by nodules of tubercle; the lower and middle lobes were congested. The left contained a cavity, with less congestion than the right. Intestines: The small intestine was thin, and the vessels full. Three small ulcers were detected, each about one-third of an inch in diameter, about an inch above the ileo-cæcal valve. The large intestine showed extensive ulceration, chiefly in the lower portions, and most marked of all in the sigmoid flexure, where several ragged ulcers with thin edges were found. The mesenteric glands, especially those lying in the folds of the meso-colon and meso-rectum, were much enlarged. Liver fatty. The other organs were healthy.

This case shows well the effect of extensive intestinal ulceration on the temperature chart, for it is probable the state of the pulmonary lesions was not sufficiently active to have greatly influenced it. The ulcerations were found in the exact positions predicted before death by the physical examination.

The diarrhœa proceeding from lardaceous degeneration of the intestines is not so marked in its characters as that arising from ulcerations. Its clinical features have not as yet been completely drawn, but it may be said to correspond with the colliquative diarrhœa of M. Peter and other French authors. It prevails in the late stages of the disease, is not very profuse, but is persistent, and seems to have some correspondence with the drenching night sweats. The stools are much more watery, and diminish after a profuse night perspiration, the tongue is more furred than red, there is less pain and no tenderness at all in the track of the intestines, but the liver is often enlarged and tender, being affected by the same kind of disease. Diarrhœa from lardaceous disease of the intestines is only to be found (in phthisis) in connexion with great discharge from some mucous surface, or with the profuse expectoration from a large vomica, or from several smaller ones. Protracted diarrhœa, as that due to ulceration, may give rise to lardaceous degeneration of the intestines, so that in many post-mortem examinations we find both ulceration and lardaceous disease present; and the question arises as to which of the lesions the diarrhœa may be attributable. This question is only to be solved by a very careful revision of the clinical history. In a fair proportion of phthisical cases lardaceous disease is present without ulceration, and here we have no difficulty in referring the effect to the proper cause. After death the appearance of the intestinal mucous membrane, especially of that of the small intestine, is pale, and sometimes there is œdema. There is no marked distinction between it and other mucous membranes until iodine is applied, when a number of small reddish-brown points appear. These correspond to the villi whose capillaries and arteries are infiltrated with the lardaceous deposit, and Dr. Green considers that the diarrhœa is due to an increased permeability of the infiltrated vascular walls, which thus allows of a flux. Usually the pancreas, spleen, liver, kidneys, and mesenteric glands are found in the same condition.

The following is an example of diarrhœa arising from lardaceous disease:—

CASE 6.—Kate H——, aged sixteen, was admitted into the Brompton Hospital on Aug. 13th, 1878. History: Chilled by sleeping in a damp bed in December, 1877, and has had cough and expectoration ever since, accompanied by great prostration and marked inanition and night sweats. Had hæmoptysis, a quarter of a pint in amount, in March, and streaked expectoration occasionally since. Diarrhœa has prevailed for the last month. Cough is very troublesome, expectoration abundant and yellow; appetite indifferent; bowels open three times a day; pulse 110. Physical signs: Crepitation is heard over the whole chest, anteriorly and posteriorly; on the right side loud tubular sounds are audible from the clavicle to the third rib; on the left side amphoric breathing and tinkling sounds as low as the fourth rib. The diarrhœa persisted in spite of a variety of treatment, the stools being loose and three to four in number; the cough persisted and the patient gradually lost flesh and died on Oct. 27th. On the 2nd of October a careful record was commenced of the temperature five times a day, and was continued up to the death on the 28th, a period of twenty-five days. During the first fortnight the temperatures were high, even in the morning; in the second period there was a tendency to fall, and in the last two days, which I have omitted as the records were only those of collapse, the temperature fell to 95·8° F., though the diarrhœa did not increase.

Averages.	8 A.M.	11 A.M.	2 P.M.	5 P.M.	8 P.M.
1st period (14 days) ..	99·2° F.	99·6° F.	100° F.	100·7° F.	101·3° F.
2nd ,, (10 days) ..	98·5° F.	98·3° F.	99° F.	99·2° F.	100·2° F.

Maximum .. 102·4° F. Minimum .. 96·8° F.

The autopsy showed that both lungs contained numerous cavities secreting puriform matter, and in the left was some fresh arborescent tubercle following the line of the bronchioles, some yellow matter filling the lumen of the small bronchi. The intestines, small and large, were intensely lardaceous, giving strong reaction with the iodine; the liver was enlarged, and both it and the spleen and kidneys were all markedly lardaceous.

Remarks.—This is a fair instance of diarrhœa arising from lardaceous degeneration of the intestine, as no ulceration could be detected, and the whole intestinal tract, in common with other organs, was infiltrated with the material.

Treatment.—The treatment of the first form of diarrhœa need not detain us long, as it consists of simply correcting the dietary and ordering a few doses of alterative and purgative medicine, with some alkali to reduce the acidity. The second form—that arising from ulceration—requires very careful attention. The great point to be kept in view is the healing of the ulcers, and this can only be attained by shielding them from all irritable substances, and by promoting a healthy granulating action. The treatment, in fact, resolves itself into three sets of measures.

1st. Rest in bed and the administration of only such food as can be quickly and easily assimilated without causing much distension of the intestine or accumulation of flatus. Such are chicken-broth, beef and veal tea, milk gruel, blancmange, always combined with liquor pancreaticus, and prepared after the admirable methods of Dr. Wm. Roberts of Manchester. Dr. Jagielski recommends koumiss specially in these cases.

2nd. Warm applications to the abdomen in the form of linseed poultices, turpentine stupes, or hot water fomentations, to reduce the pain and promote a certain degree of derivation to the skin. If the pain be severe, I have found the application of a small blister over the area of tenderness on pressure, as recommended by Dr. J. E. Pollock, very advantageous. I have noticed in some obstinate cases that when the blister has risen, the diarrhœa has been considerably reduced, and pain existing in the abdomen at the time has subsided.

3rd. Internal medicines: When we have reason to believe that the ulceration is slight and confined to the small intestine, the diarrhœa may be treated by bismuth and opium, or by some astringents. The liquor bismuthi et ammoniæ citratis (B. P.) is a convenient form, but not always so effective as the powdered carbonate or the nitrate of bismuth in ten to twenty-grain doses. Dover's powder combined with it in ten-grain doses is often effective. The most powerful astringent is the sulphate of copper in a quarter to half-grain doses combined with half grain to a grain of solid opium. Of the various vegetable astringents I have found tannic acid in four-grain doses to answer best, far better than rhatany and catechu, but in all cases I combine it with a certain amount of opium to reduce the irritability of the ulcers. Indian bael, especially a preparation of the fresh fruit, is often efficacious in checking the diarrhœa if the ulceration be limited. If, however the ulceration attack the large intestine as well as the small, it is obvious that more local treatment is advisable, and recourse should be had to injections or suppositories. The enema opii (B. P.) administered twice a day is sometimes sufficient, and may be strengthened by the addition of acetate of lead, four grains to an injection, or of tannic acid, five grains. This is a small injection, and it is doubtful how far its local effect reaches. Where the ulceration is very extensive, and involves the greater part of the large intestine, an attempt ought to be made to apply the remedies more thoroughly to the mucous membrane; and for this purpose injections of larger amount—from a pint to a pint and a half—may be used, consisting of gruel or of starch, or, best of all, of linseed-tea, and all containing a certain quantity of opium (thirty to forty minims of the tincture). I would specially recommend the linseed-tea, as it appears to exercise the same beneficial effect on the ulcers of the large intestine as it does in follicular ulceration of the throat. One of the most obstinate cases of intestinal tubercular ulceration I ever witnessed yielded to linseed-tea injections, after almost every other treatment had been vainly tried, the ulcers apparently healing, the diarrhœa ceasing, and the patient living for two years afterwards, and dying of pulmonary lesions. In cases where the stools are very fetid, I have added glycerine of carbolic acid to the injection with advantage. In many cases, however, it is desirable to give the large intestine as much rest as possible, and not to stretch the ulcerated mucous membrane through any distension by fluids; in these cases suppositories of morphia (from half a grain to a grain), or of the compound lead one, or of those of tannic acid are indicated, and the treatment of the diarrhœa arising from lardaceous degeneration of the intestine is not very hopeful. Where the very channels of assimilation—viz., the villi—have undergone degeneration, as well as the various structures from which the succus entericus is poured out, it is difficult to see how treatment can restore the lost tissues. Dr. Dickinson's researches show that the loss of alkali is the chief characteristic of the disease. Dr. Marcet's analyses show that the chief chemical feature is deficiency of phosphoric acid and potash, and excess of soda and chlorine, and on this principle we should give phosphates of potash. When, however, the disease has so far advanced as to reach the intestine, it may be considered beyond any effective general treatment. We must be content to restrain the diarrhœa if we can by astringents, the more powerful the better. Tannic acid in from two to four grain doses, with dilute sulphuric acid, sulphate of copper or sulphate of zinc are the most useful, and injections of these substances do some good.

Upper Brook-street, W.

TREATMENT OF COMPOUND FRACTURES AND WOUNDS OF JOINTS BY GLYCERINE AND CARBOLIC ACID.

By F. C. G. GRIFFIN, M.A., M.B. OXON., M.R.C.S. ENG.,
SURGEON TO THE WEYMOUTH ROYAL HOSPITAL.

AS various modes of antiseptic treatment continue to be brought forward, and the most opposite opinions are still held as to their merits, I have thought an account of a few cases that I have treated with the glycerinum acidi carbolici of the British Pharmacopœia, without antiseptic spray or any very elaborate precautions, would be of general interest. And although the number of cases is not large, still the fact that they have all got well has produced a strong impression on my mind of the value of this mode of treatment.

A pipe manufacturer of intemperate habits, who had failed in business and taken to fishing, was engaged in hauling in a net, with others, after dark, when he got his leg caught by a loop of rope and was thrown down, and found himself unable to rise. The fishermen carried him home, but handled him rather roughly, as they thought he was not seriously hurt. When I saw him I found he had sustained a compound fracture of the tibia, at the junction of the lower and middle thirds, and had lost a large quantity of blood from a small wound caused by the upper fragment of the tibia having been driven through the skin. I bound it up temporarily, to arrest the bleeding. After about twelve hours, when the bleeding had at length quite stopped, the temporary dressing was removed, and a pad of lint soaked in collodion applied. This pad remained on for two days, when it became partly detached, and free oozing of bloody fluid commenced from the wound. I now applied a pad of four thicknesses of lint saturated with glycerinum acidi carbolici to the wound, and a few turns of bandage over it, so as to keep it in its proper position. The lint became firmly adherent to the wound, and the next day I applied a larger pad of four thicknesses of lint soaked in the same way over the original pad, so as to keep it still saturated. On the third day afterwards I cut the edges of the two outer layers of the pad next the wound, and removed and soaked them with glycerinum acidi carbolici, and then reapplied them, and then the bandage as before. I will here state that I regard it as of much importance to the success of this plan of treatment not to disturb the layers of lint immediately covering and generally attached to the wound. After this treatment had been continued about ten days, a large blister containing dark fluid formed under the pads and showed at their edges. I now cautiously tried whether the under pad was still adherent, and finding it was not, I removed it and found that the wound had healed. I left the blister exposed to the air, and it dried up in a few days. The remaining progress of the case in no way differed from that of one of simple fracture, and the man ultimately completely recovered. I was informed by this man's wife that previous to the accident he lived almost entirely on beer, and took scarcely any solid food except a little bread, and that if she provided him with a good dinner he used to sell or exchange it for more beer. While he was under my treatment I limited him to a pint of stout daily.

The next patient treated in this way was a boy of about ten years of age, with compound fracture of the tibia, the upper fragment of the bone having been driven through the skin. The glycerinum acidi carbolici was applied on four thicknesses of lint about two hours after the accident, and covered with cotton-wool, and fresh glycerine and acid was applied to the lint daily, without disturbing the layers next the wound. After about ten days the lint was removed, and the wound found to have healed. A speedy recovery followed. The fracture apparatus used was of the same kind as in the following case.

The next patient was a tradesman who had jumped out of a cart while his horse was running away. He in consequence sustained a simple fracture of the fibula and a compound dislocation of the foot outwards, the lower extremity of the tibia being driven through the skin, the sock, and the elastic of his boot against the ground, and the internal malleolus broken off. When he had been conveyed home the bone was still protruding, and the wound could not be got at until his boot and sock had been cut away. The bone, being covered with dirt from the road, was now carefully cleansed, and with the aid of two other surgeons, who had been sent for at the same time as myself, and arrived soon after, an attempt to reduce the dislocation was made. We did not, however, succeed in effecting the reduction until a slice of bone had been sawn off the projecting end of the tibia. After the reduction the limb was placed on an iron back splint, with two wooden slide splints duly padded and suspended from a cradle, the apparatus being of the kind used at St. Bartholomew's Hospital, in the wards of Sir James Paget when he was surgeon there, and supplied by Ferguson, the surgical instrument-maker. About three hours after the accident I syringed out the ankle-joint with a solution of carbolic acid in thirty-nine parts of recently boiled water, and then, after cleaning round the wound, applied a pad of lint of six or eight thicknesses, saturated with glycerinum acidi carbolici, taking care that the upper layers were of sufficient size to project some little way beyond the wound, so as to exclude air effectually, in case of the patient becoming restless. This was then secured by a bandage. The next day all the upper layers of lint were removed, soaked as before, and then reapplied, except the three next the wound, which were left undisturbed. Then over the lint I put a large piece of carbolic acid plaster, and secured it with a bandage. This mode of dressing was repeated night and morning for several weeks, during the whole of which time not more than about a tablespoonful of discharge escaped from beneath the pad of lint. This discharge was of a pink colour, opaque, and nearly solid. The bowels were confined, and pain and starting relieved with tincture of opium, for about a fortnight. After this the patient, who ate heartily his ordinary diet of meat, &c., the whole time, used to sit up in bed and write letters, and keep the accounts relating to his business. After six weeks I gradually reduced the amount of the carbolic acid by adding more glycerine, and when the wound was nearly healed I used spermaceti ointment. He ultimately made a good recovery, and can walk considerable distances with the aid of two sticks.

The next patient was a cabdriver, aged about fifty years. His horse fell down as he was driving, and while endeavouring to hold him up, he was pulled off his seat, and broke his leg. He was then taken to the Weymouth Royal Hospital, distant seven miles from the scene of the accident. On his arrival there, I found that he had a lacerated wound about three inches long, through which the end of the upper half of the tibia was protruding. After the fracture had been set, and the edges of the wound drawn together, except over the seat of fracture, where, in consequence of the swelling of the leg, the skin would not meet without more force being used than appeared desirable, a pad of lint of about four thicknesses was saturated with carbolic acid and glycerine, and lightly bandaged on. The fracture apparatus used consisted of an iron back-splint, with two wooden side-splints, padded and suspended from a cradle, as in the previous case. Over the pad a piece of carbolic-acid plaster was placed. The next day a fresh pad of about four thicknesses was soaked as before mentioned, and applied over the previous one, and the plaster over them both. This dressing was repeated night and morning for about a fortnight, after which it was reduced to once a day. The man was on ordinary diet throughout, and there was no constitutional disturbance. About a month after the accident the lint next the wound was for the first time removed, and the wound found to have healed, except over the end of the bone, where there was a wound about an inch long, with bare bone exposed. The special treatment was now discontinued, and poultices were used. A little later a thin layer of bone came away, and the wound then soon healed, and the man recovered with a useful leg.

The next patient was a brewer's drayman, a large made and very fat man, accustomed to the free use of the beverages he supplied. His horses started off while he was in a public house, and when he ran to their heads and endeavoured to stop them he was knocked down, and before they could be stopped the front wheel of the dray going over the inner side of his knee, turned back a large flap of skin, and made a lacerated wound that extended into the knee-joint. A surgeon was called, who dressed the wound, put in some stitches at suitable points, and gave the foregoing account on resigning charge of the case. When I saw him a large pad of four thicknesses of lint, saturated with the glycerinum acidi carbolici, was applied over the wound, and kept saturated by fresh supplies on its outer surface renewed daily. For a week or ten days all went well, and no trouble connected with the joint occurred afterwards, but at the end of that time the lint came off and poultices were used instead, the edges of the skin flap being found to be sloughing, and erysipelas of the leg commencing. The erysipelas followed a severe course, as it did also in several other cases that occurred about the same time, but in the end he recovered and returned to his occupation as drayman.

The next patient was a builder's workman, who fell from a scaffold eighteen feet high, thereby sustaining a severe compound fracture of the lower jaw, while another man falling upon him broke his thigh, and the bone coming through the skin wounded the internal saphenous vein, and caused such copious bleeding that the man appeared in danger of immediate death from loss of blood. Under these circumstances a large sponge was bound tightly over the wound, and the bleeding thus arrested. The fracture was then set, a long splint and bandages being used in the ordinary way. The treatment having reached this stage when I first saw the man, who was cold, perspiring profusely, with livid face, and evidently almost dying from loss of blood, I applied the glycerinum acidi carbolici freely to the bandages over the sponge, and then lightly bound over them four thicknesses of lint saturated with it. The next day I removed the lint, cut slits at short intervals in the bandages, and injected the glycerine through them with a syringe and along the upper edge of the sponge, and then reapplied the pad of lint freshly saturated as before. This treatment was continued for a fortnight without disturbing the sponge, after which the sponge was removed, and the wound found to have healed. The man's health improved throughout, and he recovered in about the same time as if it had been a simple fracture of the thigh.

Weymouth.

MR. HUTCHINSON commenced his course of lectures on "The Laws of Inheritance in relation to Disease," in the theatre of the Royal College of Surgeons, on Monday last. This lecture, as well as that delivered on Wednesday, was attended by an unusually large and appreciative audience, the President of the College in the chair. Sir J. R. Bennett, late President of the Royal College of Physicians, several members of his College, and other distinguished visitors were at the first lecture.

ON SOME

RARE FORMS OF DISEASE, ACCOMPANIED BY LESIONS OF TROPHIC NERVES OR TROPHIC CENTRES, AND ILLUSTRATIVE OF TROPHIC CHANGES.

BY WILLIAM ALEXANDER, M.D., F.R.C.S.

DURING the past two years the surgical practice of the Liverpool Workhouse has presented for observation some rare and interesting forms of disease, all probably dependent upon changes in the nerve centres, and all accompanied by changes that are commonly referred to the disordered action of trophic nerves. The first case seems to be unique in the combination of symptoms. It is similar to no other disease described in our best text-books, and its publication is necessary to ascertain whether it has been described before, or if it may be looked upon as an indigenous form of true leprosy.

CASE 1. *Irregular symmetrical pigmentation of the body, accompanied by anæsthesia of the pigmented patches.*—A delicate girl, eighteen years of age, was admitted into hospital in November, 1879, suffering from endo-cervicitis and metritis of gonorrhœal origin. The canal of the os uteri was much contracted, and the disease very intractable. This necessitated a prolonged stay in hospital, and enabled us to test thoroughly the truth of the statements about to be made. Shortly after admission a considerable portion of the patient's body was found to be covered by a yellowish-brown pigmentation. The upper extremities were almost covered by it, with the exception of some white spots at the flexures of the elbows, that by contrast with the skin around appeared almost pearly in hue. The thighs were much less stained, and below the knees only a few fugitive spots could be seen. On each cheek there was a small faint spot. Below the lower lip, and beneath the chin, were distinct median patches, and these two were the only median patches on the body. On the right side the lateral regions of the body were more affected than on the left. On the right the mamma and scapular regions were covered with pigmentations, whilst on the left the same regions were scarcely touched upon. Over the anterior part of the abdomen, at the inner part of the junction of the lumbar and iliac regions, were two deeply pigmented sickle-shaped patches, perfectly alike in hue, shape, size, and location on their respective sides of the body. On the dorsal region a few spots existed between the inferior angle of the scapula and the iliac crest. Across the centre of the left iliac crest lay a long crescent-shaped patch that was just saved from being asymmetrical by some scattered spots on the opposite side of the body. Like the next disease the pigmentation was symmetrical, and did not affect the median line except on the face and neck.

The discolouration might be described as brown, brownish-yellow, or yellowish-brown. There was no infiltration of the skin, no elevation of the affected surface, and no evidence of papillary or fungoid growth. Her dark hair had recently become dashed with about one-sixth of grey. The most important feature of the case remains to be mentioned—viz., an easily appreciable and constant amount of anæsthesia in the discoloured skin. This was tested by numerous observers again and again, and though some patches were more anæsthetic than others it was estimated that sensation to touch was one-third less than normal. The anæsthesia was in some parts not quite coincident with the pigmented areas, but more extensive, and in other places the derangement was more paræsthetic than anæsthetic.

Present condition (Sept. 1880).—The pigmentation has increased considerably, and encroached still further upon the median region of the body. The anæsthesia has also spread with the pigmentation, but is not more intense than when admitted. Patient has during the last three months passed through an attack of secondary syphilis, including a scaly rash on the skin, sore-throat, &c., complicated with ovaritis and metritis.

Previous history.—Patient had (up to a few months before admission) always been an active healthy girl until she caught the disease for which she came into hospital. She had never been out of England, and never had syphilis. When she was five years of age the brownish marks appeared on the back of the left hand, then spread up that arm, and subsequently showed themselves on the right hand and arm. The subsequent progress of the disease she did not particularly notice, and could not give the chronological order of the appearances of the other spots.

Before making any remarks on this peculiar case, it will be well to compare with it the following example of a disease sufficiently rare in this country to excite much interest on that account alone.

CASE 2.—*Elephantiasis Græcorum relieved by the administration of chaulmoogra oil.* Henry O——, aged forty, a sailor, was admitted into the hospital on September 28th, 1878, with what appeared to be chronic indurated erythematous œdema of the face, and with blisters on the right foot and on both hands. The patient was rather amused at our attention to his face, the redness of which he thought arose from the hot sun and would soon pass away. Simple applications cured the blisters by November 7th, when he was discharged. He was readmitted on November 19th with another and more severe crop of blisters on the feet and hands, and with the skin of his face raised in red shining tubercles. These tubercles only affected the naked (not the hairy) part of his face. Arsenic was at first prescribed without any benefit. On February 25th, 1879, he complained of pains and numbness in the hands, and on stripping the patient the arms, thighs, and lateral regions of his body were found to be covered with dark brown pigmented patches which were distinctly and in some places completely anæsthetic. On admission to the hospital he had no discolourations anywhere. Since his admission he observed them coming, but did not call attention to them as similar spots came three years ago and disappeared without any treatment. As leprosy was now for the first time suspected, a more pertinent inquiry was made into the history of the case, when we found that he had sailed for many years to Australia, India, and other Eastern and leprosy-infected places; that he began to suffer pains in the extremities three years ago, when in Australia; that these pains increased during visits to Calcutta and Rangoon; that at Calcutta he was told his disease was latent leprosy; and that on his last voyage from India to Liverpool, previous to his admission here, the skin of his face became reddened and thickened. He has always been a healthy man, and never had syphilis. The pigmentation on the arms is of a dark or greyish-brown colour, and the pigmented skin is here raised into tubercles, especially over the area of the cutaneous distribution of the ulnar nerves. These nerves can be felt as rounded cords at the elbow, where slight pressure produces a tingling sensation similar to that produced by a sudden and unexpected shock on the "funny-bone." On the rest of his body the anæsthesia and discolouration very closely coincide in appearance, amount, and cutaneous distribution with the case of the girl previously described. The face has a peculiar appearance, the nose, cheeks, forehead, and eyelids being the seat of crimson tubercles, which are streaked with branching purple-coloured vessels, so that his features have at a distance an intense hot glow like that temporarily produced on some people by strenuous exercise on a hot day. Any doubt of the true nature of the disease was removed by a visit from Dr. Henderson of Shanghai, who at once pronounced it "a typical case of true leprosy in the early stage." Gurjun oil was prescribed and persevered in for nearly four months, during which time the disease continued to spread. Cod-liver oil was then tried for two months with the same result. He has now taken chaulmoogra oil for more than a year, and the result has been that the redness and induration have to a great extent disappeared from the face. Anæsthesia is now nowhere to be found; the tuberculisation of the ulnar regions has almost gone, and his pains have long vanished. Blisters have showed themselves once or twice during the year, but they were small. He is now taking eighty drops of the oil daily, which is as much as his stomach will bear. The patient is a very intelligent man, and being aware of the serious nature of the disease co-operates in every way in the carrying out of the treatment. When he gets sick of taking the medicine in one form, he tries it in another, and up to the present time his stomach has borne the drug very well.

Remarks.—Temporary irregularity in the distribution of pigment in the body is a comparatively frequent phenomenon. When anæsthesia accompanies this irregularity the irregularity is almost always one of deficiency rather than of excessive pigmentation. When the irregularity in the distribution of pigment is permanent the same statement is true, except in leprosy, where there is a deepening of the normal pigmentation. In that disease, however, there are also induration and tuberculisation of the skin. Chloasma, vitiligoidea of various kinds, melasma, pityriasis versicolor, and morbus Addisonii resemble the disease in Case 1, as far as the discolouration is concerned; but I am not aware that anæsthesia has ever been mentioned as an accompanying symptom of these diseases. The location of the pigmentation in the girl's case does not correspond with the area of distribution of any of the cerebro-spinal nerves, thus excluding disease of the nerve-trunks after their emergence from the central nerve-substance. There is no evidence of a local cutaneous cause for the anæsthesia. We are, therefore, driven to the central nervous system as the most probable seat of the affection. That the distribution of pigment is under the control of the nerve-centres the rapid blanching of the hair in cerebral disease and by mental anxiety fully testify. G. Pouchet (*Journal de l'Anatomie et de la Physiologie*, 1876–77) has shown by experiments on fishes that the change of pigmentation that often takes place so as to assimilate the hue of the fish to that of its habitat is brought about by reflex action through the optic nerves, and when both eyes are removed the change does not take place. His experiments show that other reflexes than visual may affect the distribution of pigment. But trophic changes and pigmental lesions are supposed to be under the direct control of the trophic and vaso-motor nerves, which are supposed to arise from the grey matter of the cord close to the origin of the sensory nerves. This tract has never been satisfactorily defined, but the almost perfect coincidence of the anæsthetic and pigmented areas in this girl point to an identity of origin; and the reason why pigmentation does not always accompany anæsthesia probably is that the nature of the disease that can produce both symptoms is different from the common degenerations that are accompanied by anæsthesia alone. Case 1 is therefore probably caused by an ascending and descending degeneration of a region in the cord, but the exact position of that region is uncertain. The similarity of this disease with leprosy, as described in Case 2, is so striking, that, having formed my opinion as to the spinal origin of the first, I looked to see if authorities on leprosy had mentioned a nervous origin for that disease. Nothing is said upon the subject in such books as I have had access to; but in THE LANCET of May last there is a report of the condition of the spinal cord in leprosy by S. Tschirew. Danielssen and Boeck in 1848 described a rarefaction of the ganglionic cells of the grey matter with altered consistence and volume of the cord. Tschirew found thickenings, hæmorrhages, infiltrations, and nuclear growths in the cervical region, and throughout the cord lesions, more or less severe, of the posterior roots.

(To be concluded.)

CASE OF RABIES IN A DEAF-MUTE.

BY JOHN TAYLOR, L.R.C.P. EDIN., L.F.P.S. GLASG.

ROBERT H——, aged six, deaf-mute, a bright, agile, healthy boy, was bitten by a stray dog on the 6th of March, 1880. I saw him a few minutes after the occurrence and found two wounds—one two inches long over the right eyebrow, slightly exposing the pericranium, and the other three-quarters of an inch long, over the left eyebrow. They were promptly washed and cauterised, and healed rapidly. The dog was lost sight of, and the meagre information that could be obtained respecting it left the hideous suspicion that it was not in a good state.

Nothing unusual was observed in the boy's demeanour until the 5th of August. On that day there was an absence of his wonted eagerness for play, and a marked increase of his natural timidity. This was followed by a restless night. Next morning I found him in a fitful condition. Seized with sudden terror he would cling as if for protection to some one in the room, or rush off to hide behind the furniture. Being soothed he would sit down quietly and respond with his customary smile and interested look.

August 8th.—Pulse 153; pupils dilated; paroxysms of terror more severe; slight hesitancy in swallowing; remarkable hyperæsthesia—the slightest current of air producing a gasp, a shudder, a shriek, and a struggle, reminding the onlooker of a timid bather who suddenly gets out of his depth. Any attempt to sponge his face is resented with the utmost fury. Half a grain of acetate of morphia gave uneasy slumber for three-quarters of an hour. Its subsequent administration was ineffectual.

11th.—Pulse 123; distressing dysphagia. He willingly offers to take some beef-tea, but in doing so he suspends it in the mouth, compresses the lips, sucks in the cheeks, raises the shoulders, and moves the entire body in his efforts to swallow. Suspecting the liquid, he wishes others to partake of it, watches them narrowly, and tries the same dish and spoon he has seen them use. Signing for cold water, he clutches the vessel in his own tremulous grasp, spasmodically bites the edge of it at each mouthful, and holds it aloof till the act of swallowing is accomplished. Hallucinations of sight and feeling. Micturition frequent and difficult. Former symptoms aggravated. Half a grain of morphia injected hypodermically gave three hours' restless unconsciousness. Its subsequent administration produced no appreciable effect.

14th.—Pulse 168; great muscular weakness; features contracted; eyes unsteady. Upper part of the face covered with nail-scratches from spasmodic endeavours to protect the eyes from imaginary danger. Expectoration of viscid saliva. Vomiting of small quantities of frothy cream-like fluid. Persistent grinding of the teeth, with occasional dropping of the lower jaw, thus giving the appearance of "biting the air." The patient afterwards sank into a writhing semi-conscious condition, which was varied by convulsive seizures, and short lucid intervals of consciousness. Death from exhaustion.

Besides the evident peculiarities of the absence of disturbance from sound, and the long duration of both the incubative and active stages, it may be worthy of note that the patient could have no suspicion whatever of the nature of his complaint, and that he did not exhibit the slightest symptom of approaching asphyxia.

Cleland, New Zealand.

EXTRAORDINARY CASE OF SUICIDE.

By ROBERT JAMES MORICE, M.D.,
COLONIAL SURGEON FOR THE NORTHERN TERRITORY OF SOUTH AUSTRALIA.

THE following case of suicide which lately came under my notice is so remarkable that I think it ought to be recorded, although I did not myself see the body, and only obtained my information from non-medical witnesses.

E. B——, aged forty-five, gold miner, was a man of somewhat intemperate habits; he would have occasional "bursts," as they are called here—that is, he would be drunk for a week or so, and would then keep sober for a few months. Such had been his habits for some years. For a few days previous to his death it was noticed that he was not drinking, having just finished one of these periodical bouts. On the morning of June 22nd, 1880, his body was found lying dead outside the tent in which he lived. His throat had an incised wound across it two or three inches long, but not deep, the windpipe being uninjured. This wound appears to have been inflicted with a blunt table-knife, which was found, covered with blood and short hairs resembling those of his beard, in a box in the tent. There was a good deal of blood on the floor of the tent. The left hand and forearm were completely severed from the body, and lying beside it outside the tent. Here I shall quote from my informant:—"There were several wounds in the upper part of the ball of the thumb; then the wrist was nearly cut through, only a piece of skin connecting the hand with the arm. Then the arm was cut through an inch or so above the wrist; both bones were cut through, and the hand and wrist separated from the arm. There was a deep ragged wound in the wrist, all the bones of which appeared to be smashed. I counted several distinct wounds on the thumb, wrist, and arm; there must have been over twenty; I counted seventeen separate ones. I imagine he rested his wrist on a piece of wood, and then chopped it, as there were several distinct cuts on the piece of wood, and marks of the blood having spouted out, the cause of death apparently being the loss of blood from the wounds inflicted." The "deep ragged wound" in the wrist is believed to have been a stab with a pointed instrument used for opening preserved-meat tins. The other wounds were evidently caused by a small tomahawk which deceased kept for chopping firewood. The tent where this happened is situated within a few hundred yards of two other tents, but no noise was heard during the night before the body was found, except some slight moans, which one of his neighbours said he heard, but the direction of which he mistook.

At the inquest one witness said that on a previous occasion deceased showed symptoms of mental derangement, but all the witnesses who had seen him shortly before his death declared that he then appeared quite sane.

I have since learned that whenever he was drunk he had a way of repeating the text: "An eye for an eye, and a tooth for a tooth; if thy right hand offend thee, cut it off." But, if it was attempting to carry out too literally this Divine behest that caused his death, we see that he made a mistake and cut off the wrong hand. Also why did he make the attempt to cut his throat, and then stab himself on the wrist? My own impression is that the desire for self-destruction came first, and then, after two ineffectual attempts, his favourite text occurred to him. What makes it more strange that he should have resorted to such a painful mode of suicide is that he must have had a loaded revolver in his tent, in accordance with the invariable custom in this country.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

WESTMINSTER HOSPITAL.

CASE OF INTESTINAL OBSTRUCTION; ABDOMINAL SECTION; RECOVERY.

(Under the care of Dr. FINCHAM and Mr. MACNAMARA.)

FOR the notes of this interesting case we are indebted to Dr. W. Gristock.

H. L——, aged fifty-two, a cab-driver, was admitted on March 18th, 1881. He stated that he had always been a healthy man. He remembered no previous illness except rheumatism, for which he was treated at a temperance hospital three years ago. He had had occasional rheumatic pains since, but had never been laid up. He was a teetotaler for twenty-six years, but gave this up about a year ago, and had since been a somewhat free drinker, mainly of whisky. He drank rather more than usual on March 16th. He has been married two years, and had one child, three months old, healthy. He had felt slight indigestion for about a week, but was practically well till the morning of March 18th, when after an ordinary breakfast at 9 A.M. he was driving his cab at 10.30, and suddenly felt a severe pain in the lower part of his abdomen and vomited four times. He took some brandy to relieve the pain, and then came to the hospital.

On admission he was a strong, healthy-looking man, but had a somewhat anxious and depressed expression. He complained of pain in the hypogastric region in severe and frequent paroxysms, and also of tenesmus. He vomited frequently. His abdomen was full and tender. There was no external hernia. Temperature 102·4°; pulse 120. His urine was diminished in quantity, but no accumulation in the bladder was found by catheter. The urine was of sp. gr. 1028, and contained no albumen. He was ordered one grain of opium every three hours, which in the evening was altered to one grain every six hours. The abdomen was fomented. Next day patient was no better. The abdomen was tense, full, and excessively tender. The bowels had not been opened. Temperature varied from normal to 101°.

On March 20th he seemed rather quieter, and the vomiting subsided in the morning for some hours, but again came on about midday. The vomit was now stercoraceous. The bowels were not moved, although the patient was put under chloroform, and a warm-water enema was administered (the tube being passed nine inches up the bowel). In the evening the patient was collapsed, and evidently in an alarming condition. At 8.30 P.M. ether was administered, and Mr. Macnamara made an incision about four inches long in the linea alba, and carefully examined the intestines coil by coil. A knot of intestine was found in the ileum (about two yards from its junction with the cæcum), which gave way with a perceptible slip as the intestines were handled. There was marked evidence of peritonitis, and the intestines were much injected and streaked with lymph. The cavity of the abdomen was cleansed and the wound closed. The operation was performed with strict antiseptic precautions. After the operation the patient was a good deal collapsed, cold and clammy, and he vomited twice. The temperature, which had risen during the day from 98° to 102·6°, fell after the operation to 97·4°. Pulse was 140, very weak and compressible.

On the 21st patient still felt cold, and his skin was covered with cold sweat. He vomited almost continuously, the vomit consisting of clear fluid with curdled milk. Twelve ounces of urine were passed in the twenty-four hours. All food by the mouth was stopped, and nutrient enemata with pepsine were ordered. He passed a slightly better night, but did not sleep more than a few minutes at a time. Vomiting continued urgent. On the 22nd he looked a little brighter. He vomited eleven times during the day. The tongue was rather less dry and somewhat furred. He was still entirely supported by nutrient enemata. Champagne was tried by the mouth, but caused immediate vomiting. Ten ounces of urine were passed, but the bowels had not moved. Next day he was decidedly better, and able to take champagne and Brand's essence by the mouth. He passed forty-five ounces and a half of urine, and after one of the nutrient enemata a small quantity of slightly fæcal fluid returned. He slept pretty well, and on the 24th was better. Tongue red and irritable. The patient had a troublesome cough, and in the evening twice vomited some thick mucus. Bowels not opened, but much flatus passed. Twenty-six ounces of urine passed in the twenty-four hours. Temperature 98·4° and 100·4°; pulse 104. The wound was dressed, and its edges were found rather red and inflamed. The abdomen was flaccid. On the 25th the patient was free from pain and sickness. The bowels were freely opened, large extremely offensive motions being passed. From this time the man made a rapid recovery. He was allowed to take bread-and-milk on the 29th, but this had to be again stopped for a day or two on April 1st, owing to a slight recurrence of vomiting with diarrhœa. There was again a little diarrhœa on April 17th and 18th, which, however, was readily controlled. The wound after the first few days gaped, and the stitches cut through the skin, and after one further attempt to close the wound by harelip pins it was allowed to heal by granulations, tension being relieved, and the edges kept in apposition by strips of plaster. The patient was sent to a convalescent home on April 23rd.

LONDON HOSPITAL.

LACERATED WOUND OF KNEE-JOINT; LISTERISM; RECOVERY WITH MOVABLE JOINT.

(Under the care of Mr. RIVINGTON.)

THE following case further exemplifies the value of Lister's method in wounds of joints.

J. W——, aged sixty, a dock labourer, was admitted into the hospital on the 22nd of March, 1881, with a lacerated wound on the inner side of the right knee, caused by a blow from a plank. On examination, under the carbolic spray, Mr. English, the house-surgeon, found that the soft parts were much bruised, and that the lacerated wound, which was two inches and a half long, extended from the condyle of the femur to the inner tuberosity of the tibia downwards and forwards, and communicated with the cavity of the knee-joint, allowing the finger to pass under the patella. The wound and joint were thoroughly syringed out with carbolic solution (1 in 20) and dressed antiseptically after Lister's method. A back splint was applied to the limb.

March 23rd: Knee redressed; bruising and swelling more marked; temperature 101°; not much discharge; patient comfortable.

24th: Discharge still aseptic; some effusion into the joint, best felt on either side of the patella; patient doing well. From this date the patient progressed most favourably. The temperature rose to 102° during the evening of the 25th, and afterwards fell gradually to normal. The patient remained free from constitutional disturbance and local complication.

On April 11th the wound was nearly healed, and the patient was able to flex the knee without difficulty.

On the 30th there remained only a very small superficial surface presenting healthy granulations, remains for cicatrisation. The knee-joint was freely movable. Patient was discharged a few days later.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

TREPHINING FOR EPILEPSY.

(Under the care of Mr. J. F. WEST.)

AT a meeting of the Royal Medical and Chirurgical Society, held Nov. 25th, 1879, Mr. West read a paper on Trephining for Traumatic Epilepsy, which the Society published in Vol. lxiii. of the Medico-Chirurgical Transactions.

The girl, whose case was there reported, has had no fit since then, nor in fact any since Nov. 25th, 1879, the date of the operation. She was recently brought before the members of the Midland Medical Society, in order that they might judge for themselves how much her mental condition had improved, and how well she was able to answer any questions that were addressed to her. The undoubted success which attended the use of the trephine in that apparently idiotic, epileptic patient induced Mr. West to resort to it again in a second case; and although the result has not been so satisfactory, Mr. West thinks it would be unfair to place the success on record and to omit all mention of the failure. The traumatic origin of the epilepsy in this case was very doubtful, and operation was consequently less likely to have a curative effect. Mr. West brings this second case of trephining for epilepsy under the notice of the profession, merely because it illustrates the good results of antiseptic treatment in this operation, even when trephining does not cure epilepsy.

Eliza P——, aged twenty-five, single, was admitted into the hospital on March 4th, 1880, under the care of Dr. Heslop. She had one fit when five years old, four days after having a burn on her head. About nine years since she had enteric fever, and during convalescence rheumatic fever. Two years after this she had another fit. Since then she had had a succession of fits, never at a longer interval than twelve weeks. For the last twelve months they have come on every week. Since she was under medical treatment the fits had diminished in severity, but not in number. The fits were worse at her menstrual periods. At the age of nine she had a severe injury (a cut) on the upper part of the forehead, which was some weeks suppurating. She had passed several tapeworms during the last two years.

On admission she was a stupid-looking girl, whose stupidity was confirmed when she spoke. Over the upper part of the forehead and a little to the right of the middle line was a transverse cicatrix, which was adherent to the bone, and at the right end of the cicatrix there was a slight elevation of bone, as though at that point the periosteum had been thickened. There was no loss or impairment of motor power. The general health was fairly good. She was ordered thirty grains of bromide of potassium, with ten of bromide of ammonium, twice a day, and this treatment was pursued, though without benefit, until March 27th, when she was transferred to Mr. West's care. Although the case seemed to be rather one of idiopathic than of traumatic epilepsy, Mr. West decided to resort to trephining, being induced to do so by the fact that various methods of internal treatment had been adopted prior to her admission into the hospital without success, and also that the treatment by the bromide of potassium ordered by Dr. Heslop had not diminished the epileptic attacks while at the same time there was some thickening of the periosteum over the frontal bone at the seat of a severe injury. Moreover, it was thought that possibly the mere relief of intracranial pressure might at any rate diminish the epileptic attacks, as it had done in Eleanor H——'s case.

On March 27th, 1880, Mr. West trephined antiseptically at the site of the cicatrix, about an inch and a half above the middle of the right eyebrow, removing a disc of bone, which appeared in every respect normal, the periosteum alone being thickened, as large as a shilling. The crucial incision in the skin was brought together with silver, and that in the periosteum by catgut sutures; a small drainage-tube was inserted at the bottom of the vertical incision, and the usual Listerian antiseptic dressing applied. The wound was dressed the following day, when it was found to be free from redness or swelling. Temperature 100·8°; pulse 104; respiration 20.

On the 29th the silver sutures were removed and the edges supported by plaster straps. Slight serous discharge; wound nearly healed. Pulse 120; temperature 101·8°; respiration 22.

On the 31st the wound, which was sound except at the angles, was again dressed antiseptically. She had the epileptic aura, but no fit. Temperature 99·8°; pulse 88; respiration 20.

On April 7th the wound was all but healed. Antiseptic dressing was discontinued, and boracic ointment was applied. Temperature 98°; pulse 90; respiration 16. She had a slight fit at 4 P.M. for the first time since the operation, an interval of ten days.

On the 10th she was ordered thirty grains of bromide of potassium with twenty drops of tincture of hyoscyamus three times a day. She had a recurrence of fits on the 16th, 21st, and 30th of April, and on the 2nd, 6th, and 15th of May. The wound healed, practically without any constitutional disturbance, in twelve days. No benefit, however, resulted from the operation; the fits were no less frequent, and the mental condition of the patient became more impaired. A sort of religious monomania possessed her, and, no further treatment appearing likely to benefit her, she was discharged on May 20th.

On Oct. 28th, 1880, she was sent to the Borough Lunatic Asylum, her condition being considered dangerous. She had evinced strong homicidal impulse on various ocasions, at one time having taken up a knife and thrown it at her mother, while on another occasion she tried to put a younger sister into a tub of water. She said that the impulse to do something of the sort came upon her suddenly, and without her being excited or annoyed in any way, and that she was unable to control it. In the intervals between these attacks she was grieved at what she had done, and was rational, but had gloomy and morbid views about religion. The mother stated that the fits had been less frequent and less violent since the operation, but that the symptoms of mental alienation which had existed prior to it had been in no way benefited, and that she had at last come to the conclusion that she ought to place her daughter under restraint.

On Dec. 12th, in company with Dr. Lyle, Mr. West visited the patient, who was then at the Borough Lunatic Asylum, but found her in no way improved. She had fits badly about the menstrual period, and also at intervals of a week or ten days at other times. Dr. Lyle had given her bromide of potassium in large doses since she had been under his care, but without benefit, and he entertained no hope of her recovery.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Urticaria Tuberosa.—Treatment of Simple Fractures and Dislocations of the Bones of the Leg by the immediate application of Plaster-of-Paris Splints.—The Pathology of Acute Periostitis.—Vascular Tumour of the Face.

THE final meeting of this Society for the session was held on the 14th inst., Timothy Holmes, Esq., vice-president, in the chair. In contrast to the condition of things a month ago, when no meeting was held owing to the absence of any papers, there was more material before the Society than could be dealt with in the allotted time, and one paper had to be read in abstract. The chief subject debated was the immediate treatment of fractures of the leg by plaster-of-Paris splints, the plan being strongly advocated by Mr. Croft in a paper on the subject, in which he described a new form of applying the method, which he practically demonstrated at the close of the meeting.

The first paper read was by Mr. MORRANT BAKER, on "A Case of Urticaria Tuberosa, with Unusual Symptoms," of which the following is an abstract:—The case related is that of a man, thirty-three years old, who had suffered from a peculiar disease of the skin for about two years, and for nearly a year had been under the care of the author at St. Bartholomew's Hospital, both in the out-patient department for diseases of the skin, and as an in-patient. The general symptoms from which the patient suffered were those of factitious urticaria, to which were added those of so-called urticaria tuberosa. The most peculiar feature of the case, however, and one which in the author's experience was unique, was the presence of persistent yellowish-red tubercles in various parts of the body, which proceeded to ulceration, the parts most affected being the knuckles, elbows, and ears. These tubercles are said to have begun in a manner similar to that which characterised the onset of the evanescent urticaria wheals and tubercles. The patient's general health was good, and he had not suffered from syphilis or other serious malady. Under the influence of treatment as an in-patient the disease became rapidly better, but soon relapsed when the patient left the hospital. The author considers briefly the doubtful relationship of the disease to others less rare, which in some respects resemble it, and comes to the conclusion that the case is one of so-called urticaria tuberosa, and that the persistency of some of the tubercles and their ulceration may be due in part to the unfavourable circumstances in which the man was placed from the loss of his occupation. A drawing of the case was shown.—Dr. CAVAFY suggested that the permanent ulcerating lesions might be due to chilblain complicating the urticarial condition, for these lesions existed mainly on the knuckles, elbows, and ears, the seats for chilblain, which they resembled in many respects.—Mr. MORRANT BAKER, in reply, said that he was glad of the suggestion, but the tubercles in question were at their worst in the month of July, and had, moreover, existed for two years. This persistence was against the view that they were of the nature of chilblains.

A paper was then read on the "Treatment of Simple Fractures and Dislocations of the Bones of the Leg and Foot by the immediate application of plaster-of-Paris Splints (lateral)," by Mr. JOHN CROFT. Opportunity is taken by this paper and demonstration to, first, reaffirm that it is not only safe, but beneficial, to apply plaster-of-Paris splints (lateral) immediately for simple fractures of the bones of the leg and foot; second, to demonstrate the particular method of applying these splints, and how quickly and easily they may be put on; and, third, to elicit observations on the practice at the various hospitals with regard to the immediate treatment of fractures of the leg and foot. The author's experience, of five years' duration, is decidedly in favour of covering the injured or swollen part immediately; only the most severe cases of contusion and subcutaneous laceration are excepted. The special advantages claimed for these splints, as made and used for the author at St. Thomas's Hospital (for particular description of which see THE LANCET for June 8th, 1878), are uniform pressure; complete fixation of the broken bones and injured muscles; perfect adaptation to the limb and maintenance of extension; diminution of risks of pressure, sores, pains, or excoriations; diminution of risks of delayed union; facilities for quick removal and reapplication; comfort to the patient; freedom of movement allowed to the patient; simplicity and cheapness; economy of time and trouble. The author desires to popularise the use of these splints, because he has found them during five years' constant experience of great benefit to patients, attendants, and surgeons.—Sir JOSEPH FAYRER said that in the previous week he had seen the Army Hospital Corps at work at Aldershot, and had been struck with the rapid and efficacious manner in which the Bavarian splint-bandage was applied. Two pieces of flannel were moulded to the leg, the inner layer secured by pins, and the plaster spread between the layers. In five minutes a perfect splint was obtained, the pins, temporarily securing the inner layer of flannel, being removed. This splint could be opened out so that the leg could be inspected, and it seemed to him most convenient for the purpose.—Mr. HOLMES questioned the accuracy of the inferences drawn from the tables accompanying the paper, with the view to show the practice in vogue at various hospitals in treatment of fractures. The return from St. George's Hospital was not accurate, so far as his own practice was concerned, for he was constantly in the habit of having such fractures put up in immovable splints, the patients going out in a few days instead of weeks after admission. He agreed with Mr. Croft as to the general benefit derived from immediate treatment, and did not think this was so little recognised as the author inferred.—Mr. HEATH asked if Mr. Croft deemed the practice a novel one. It was the same plan as that adopted many years ago by American surgeons, and the Bavarian method was well known to be a good one. As the author had said, the principle was adopted at the University College Hospital, and at other hospitals too. He himself preferred the plaster-of-Paris bandage, which took a shorter time and gave better results than other measures. The great point was to swathe the limb in cotton wadding (preferable to cotton-wool, which adheres to the plaster) before applying the bandage. This method is strongly upheld in a small but very practical book by the late Mr. Cowling of Louisville, entitled "Aphorisms on Fractures." Mr. Heath said that he invariably treats fractures of the thigh in children with this bandage, which has the further advantage of being able to be varnished when dry. Again, in fractures of the patella he found the best results to follow the application of this bandage, the effused blood in the knee-joint being first withdrawn by the aspirator. In that way good and firm union was ensured.—Mr. HOLMES said that the form of immovable apparatus he employed was composed of splints of thick pasteboard, over which a starched bandage was applied. He preferred this to the heavier plaster-of-Paris bandage, and it was quite as efficacious.—Mr. GANT pointed out that the closed immovable bandages were only applicable to cases which were seen very shortly after the injury; when (as usually happens) the case is not seen till a few hours after the fracture has occurred, the pain, swelling, spasm, &c. rendered such fixed bandages unbearable; but they could be borne later in the case.—Mr. WALTER PYE thought it would be generally conceded that simple fractures of the leg could be treated as out-patients by the use of stiffened bandages; and he preferred the old-fashioned gum-and-chalk bandage for this purpose. It was elastic as well as stiff, so that it yielded slightly; whereas the plaster-of-Paris was heavy, and liable to become brittle. The use of gum and chalk was much advocated by the late Mr. Smee, and its advantages did not seem to be sufficiently appreciated.—Mr. WILLETT said there was no novelty in the principle, although there was in the particular method adopted by Mr. Croft. When he was a pupil at the Brighton Hospital, twenty-five years ago, it was customary to treat simple fractures of the leg by splints, composed of interlacing bandages, stiffened on each side of the limb by a mixture of white of egg and flour. In two or three days a layer of wool and starched bandage was substituted. There were two points which should be carefully considered by those who were in the habit of putting up the bulk of cases of fracture on this principle. He had seen a case where gangrene had resulted, and quite recently had met with a badly set Pott's fracture with considerable deformity in a patient who had been so treated. The great difficulty in this treatment was in some cases of Pott's fracture, or in cases where there was much mobility, where it was not easy to secure such apposition of the fragments as to justify the permanent putting-up of the limb. The same difficulty occurred in oblique fractures, with great tendency to displacement. He asked whether Mr. Croft, in saying that the fractures were put up on the "first visit of the surgeon," implied that he himself applied the splints, or whether this was done in his absence by the house-surgeon.—Mr. ARTHUR DURHAM said it was a great mistake to treat all fractures in the same way; the plan which was best in one case was not the best for another. In some cases the immediate application of plaster-of-Paris was the best, but in others it was the reverse—as in a case, now in Guy's Hospital, of extreme deformity from a badly set fracture which had been put up in another hospital in plaster. Referring to Mr. Heath's remarks about the immediate treatment of fracture of the patella, he himself had excellent results from the use of back splints and plaster. Good results are not due to any particular method, but to the degree of skill and judgment with which the method is applied. A great objection to the immovable permanent bandages was that the surgeon could not see what was taking place during the process of union; and he had often seen this objection practically exemplified when such bandages had been opened. As a general rule, it was a good plan to keep the fractured limb under view until one was sure that firm union had taken place.—Mr. HENRY MORRIS asked Mr. Croft whether the plaster splints were only applied as high as the tubercle of the tibia; for it was generally believed, especially in cases of oblique fracture in the upper and middle part of the leg, to be important that both knee and ankle-joints should be fixed.—Mr. CROFT, in commencing his reply, read a letter from Mr. MacCormac (who was unavoidably absent), in which he said that he had found the plaster-of-Paris splints so satisfactory that he had been in the habit of using them for years. He uses narrow strips anteriorly and posteriorly, secured by a bandage soaked in the plaster, which bandage is cut if the limb has to be unpacked. When the swelling subsides he opens the splint and applies another bandage round it. He advocates the application of the plaster next to the skin. Dr. Yandell of Louisville had also written to the same effect, and spoke emphatically in favour of the immediate treatment by plaster splints. Mr. Croft said that there had been less objection to the immediate application of the splints than he had expected. He apologised if he had erred in basing his inferences as to the treatment in other hospitals from returns published by the registrars. He claimed no novelty for the principle, but he claimed that since its introduction it had been the means of revolutionising the practice at St. Thomas's Hospital. It mattered little whether flannel or cotton wadding was used underneath the plaster. He had adopted with advantage the plan referred to by Mr. Heath of a preliminary aspiration of the knee-joint of serum and blood in fracture of the patella. The house-surgeons put up the fractures, and they had always been sufficiently enthusiastic and intelligent to carry the method out without mistakes. By the aid of chloroform there was no excuse for the surgeon not putting up a Pott's fracture or an oblique fracture at once, and whether the limb were swollen or not it should be put up in the plaster material, which would soon set. If the fracture were properly set it could not be disturbed, and the surgeon would be perfectly confident that when viewing the limb six weeks later it would be in the same position as when first put up. Unfortunately, accidents will happen; because there is good surgery and bad surgery. Some men, with every material at their disposal, can do nothing; for much depends on individual skill. The apparatus he advocated was perfectly simple, cheap, easy of application and efficient, and it gave absolute rest to the limb from the time it was first put on until it was taken off. In reply to Mr. Morris, he said that practically the splint was often carried above the knee; for it is good practice to fix both joints. The Bavarian splint described by Sir Joseph Fayrer was admirable; it was one of the stones in the foundation of the splint he had described.

A paper by Mr. C. T. DENT, on the "Pathology of Acute Periostitis," was read in abstract. The exact relation which acute periostitis and osteomyelitis bear to each other, as well as to the articular affections with which they are so often associated, have long been matters of dispute, so also have their effects with regard to the extent of necrosis, which usually follows. French and German writers hold generally that total necrosis of the shaft will not take place unless osteomyelitis has been present as well as periostitis. This view is not shared for the most part by writers in this country, and cases are on record where the removal of the entire diaphysis has been performed for the results of acute periostitis alone. The exact tissue where the changes commence in acute periostitis is also a subject of difference of opinion; some German writers especially hold that it commences in the outer cellular layer of the periosteum, and destroys the fibrous layer by suppuration. This is, however, but one form of the disease frequently seen about the lower third of the femur, and also in true whitlow (panaritium periostale). More commonly it begins in the deeper osteogenetic layer, and raises up the periosteum from the bone. This may lead to osteomyelitis, and is sometimes, though not commonly, associated with affections of the neighbouring joints. Acute idiopathic osteomyelitis as a primary affection is rare in this country. In examining microscopically the periosteum in a case of acute periostitis, unaccompanied by osteomyelitis, the author found that the inflammatory changes were chiefly situated in the deeper parts; the fibrous layer was intact, though infiltrated, and new bone was developing in it. There was no active inflammation of bone or medulla; the changes observed in the latter the author considered to be due to disintegration and breaking down of the tissues, owing to the cutting off of the vascular supply. The leg, in this case, had been amputated on the nineteenth day. Other specimens showed that the inflammation spreads from the outer to the deeper parts, chiefly around the smaller vessels. The author remarks that usually, no doubt, when these cases are met with it is not uncommon to find periostitis, ostitis, and osteomyelitis all existing together, yet it is none the less important to distinguish them from each other as far as possible, and also from the form of disease attacking the outer cellular layer of the periosteum, for when modified by early treatment the ultimate results are very different.

Mr. CLEMENT LUCAS exhibited a remarkable case of Vascular Tumour of the Face, which had been under treatment for three years, and was gradually increasing. The patient, a man twenty-eight years of age, was healthy up to the age of eighteen, when the swelling began on the right cheek, beneath the eye, with much pain, attributed to carious teeth, which were extracted. Three years ago a pulsating tumour reached from the ear to the side of the nose and upper lip, and from the orbit to the jaw. A harsh bruit was heard over it. Mr. Lucas tied the external carotid (with difficulty owing to the large size of the veins), and the pulsation ceased for some weeks, then recurred, and the tumour increased in size. Electrolysis was then tried —first with one pole within and the other outside the tumour, and then both inside. Some consolidation followed, but was not permanent. Then galvano-puncture, which produced considerable bleeding. Then he tried excision of some portion; but most profuse hæmorrhage, to the extent of two pints, occurred, and fourteen or fifteen ligatures had to be used. The coronary artery had been tied, and the galvanic cautery used, and altogether he had operated fourteen times. The eyeball is now projecting, and the whole side of the face is occupied by the vascular mass. He had brought the case to have suggestions from the Fellows as to further treatment. He had not tried injections, fearing ill results, for he had seen a child die suddenly after the injection of a nævus.—Mr. HOLMES would shrink from the dangers of injecting any material to promote coagulation in a growth so closely connected with large veins, and suggested that some of the larger vessels, veins as well as arteries, entering the mass, might be ligatured, and that in the rapidly growing portions the galvanic wire might be passed into and beneath the tumour in various directions, so as to produce cicatrices in all parts. The late Mr. Travers, jun., once brought such a case to St. George's Hospital, and treated it on this plan, hæmorrhage having taken place. The patient remained well for some years, then the bleeding recurred, and the carotid was ligatured to check this; but the man died of hæmorrhage whilst the ligature was still on.—Mr. H. MORRIS saw the case eighteen months ago, and suggested that, in addition to tying a large vessel entering the growth, the left external carotid should also be tied, owing to the free anastomoses which exist between the two sides. If at the same time continuous cold was applied by means of Leiter's tubes, coagulation might be promoted. The efficiency of these tubes was well seen in a case of a vascular thyroid tumour now in the Middlesex Hospital, under the care of Dr. Douglas Powell, and the same application had caused remarkable reduction of a lymphadenomatous mass in the axilla and above the clavicle in a patient under Mr. Morris's care.—Mr. LUCAS asked whether ligature of the common carotid would be advisable, seeing that the chief supply seems to be from the ophthalmic artery.—Mr. HOLMES thought it better to wait for more decided evidence of the implication of the ophthalmic artery.—Dr. POWELL suggested that the condition might be largely one of dilatation of the superficial vessels from some nerve derangement. It would be worth while to try the effect of continuous cold, which had proved so effectual in the case alluded to by Mr. Morris.—Mr. LUCAS had not yet tried the application of cold, nor the plan of dividing the mass in various directions by the galvanic cautery, as suggested by Mr. Holmes. Certainly the growth began with extreme pain—thought to be toothache.

The Society then adjourned till October.

MEDICAL OFFICERS OF HEALTH SOCIETY.

AT a meeting of the Society, held at 1, Adam-street, Adelphi, on May 20th, the President, Dr. Bristowe, in the chair,

Dr. B. W. RICHARDSON read a paper on "A Study of the Periods of Incubation of the Communicable Diseases," of which the following is an abstract. The author brought forward the five following points:—1. What is the precise application of the term "incubation," and to what diseases should it be applied? 2. What is the state of absolute knowledge of the periods of incubation of the more common communicable diseases? 3. In respect of differences of opinion on this subject do they depend on fault of observation, or on the circumstance that there are in the same diseases varying periods of incubation, the variations being under no as yet defined law? 4. If it be found that there are differences of periods in the same diseases, upon what do such differences depend? 5. What are the practical lessons which arise from the facts we at present possess, and to what extent may our knowledge be rendered available in the prevention and treatment of disease? On the first of these points Dr. Richardson said that, simple as the question seemed to be at first sight, it was by no means simple. We reduced the difficulty by limiting the term to those instances of disease in which, after a certain specific poisonous particle had been taken into the living body, certain indications of the action of that specific poisonous matter have been manifested—i.e., the period between the introduction of the poison and the manifestation of its action is the period of incubation. We fail, however, to be unanimous in the question, What is the accepted first sign of such manifestation? After citing several illustrations of this diversity of view, Dr. Richardson, by exclusion threw out local symptoms as insufficient proof, together with pain and fever, but accepted as the safest phenomenon indicating that the incubation is declared that sudden vibration between cold and heat which tells the break of continuous action between the nervous and the vascular systems to which we give the name of chill or rigor. The author next added the list of diseases, twenty-five in number, which present a stage of incubation. Under the second head, the range of period of incubation in the different diseases, the diseases were classified into five groups, according to the time of incubation in each case. The classification ran as follows:—(*a*) Shortest incubations, period one to four days: Malignant cholera, malignant pustule, plague, dissection wound disease, catarrh, if it be communicable. (*b*) Short incubations, period two to six days: Scarlet fever, rosalia idiopathica, diphtheria, croup, influenza, pertussis, erysipelas, glanders, yellow fever, grease, farcy, pyæmia, puerperal fever, dengue. (*c*) Medium incubations, period five to eight days: Relapsing fever, vaccinia, variola by inoculation, gonorrhœa. (*d*) Long incubations, period ten to fifteen days: Small-pox, varicella, measles, rötheln, mumps, typhus, typhoid, or enteric fever, malarial fever. (*e*) Longest incubations, period forty days or longer: Syphilis, hydrophobia, in which the range may be from seven days to months, or even years. From these general rules Dr. Richardson proceeded to state the exceptions to them in detail, the variations being most marked in class *b*, where the periods of incubation are short. Under the third head of his discourse, on the reason of differences of opinion as to the periods of incubation, the author held that such differences are traceable to four sets of causes. First, that we have not been, up to this time, agreed as to the full symptoms that indicate the stage when incubation is complete; secondly, that until lately we have not tried to classify diseases according to the test of incubation; thirdly, that we have attached too much importance to the exceptional phenomena of incubation; fourthly, that we have been too prone to connect diseases together which are in some respects similar, but which in regard to incubation are most dissimilar. Now that we are approaching nearer to the truth we may soon be able to classify and understand the exceptions from the ordinary or natural rule of incubation. After paying a warm tribute of respect to Dr. Squire for his important labours in this field of research, the author proceeded to consider the circumstances which may lead to differences in periods of inoculation in the same affections. He suggested that as it was not known that inoculation of a poisonous particle shortened the period of incubation, so it was possible that in some cases where the poison was absorbed an accidental inoculation might account for variation of time of incubation. Again, the poison might be absorbed in one case in a form of diffusion readier for absorption in some cases than in others. But the great cause of difference was traceable to individual susceptibility, together with physiological peculiarities dependent on season and the meteorological conditions which so modify the action of the organic poisonous material. The paper was brought to a close by a review of the practical lessons which spring from the study of incubation. The points here advanced may be briefly stated as follows:—If we could arrive at definite evidence on which we could all rest, that the incubation of a disease is proved by the occurrence of a certain symptom or definite class of symptoms, we could account for much that is mysterious. For example, in vaccinia can it be that, trusting entirely to the local phenomena, we sometimes have an apparently good vaccination which never has inoculated at all? If that be so, there is a reason why the occurrence of small-pox in a person who seems to have been thoroughly vaccinated should still remain susceptible to small-pox. The suggestion, though it stand alone, is all-sufficient to indicate the practical importance of proving inoculation before pronouncing it as the protection afforded by some but not all the symptoms of a communicable affection. The division of diseases of the communicable type into different classes or groups according to the stage of incubation which is presented is a practical acquirement of the most important every day value, both in curative and preventive science. Dr. Squire has not in the least degree over-estimated this part of modern knowledge. It is quite true, as he shows, that to know when to retain at home a sick person labouring under communicable disease, when to send him from home, and when to separate him from the actual or presumably unaffected, is a direction of practical skill as eminently creditable to the profession of medicine as it is useful to the public. To remove the healthy from the affected is good practice in the case of all the diseases of the first and second of the groups of the quick and short incubation series. To remove in the third series may be sound practice. To remove the fourth or long incubation class is less important and may be a practice that is quite at fault and prejudicial. Lastly, from the study of the incubation period we learn how to assign the best means of disposing of the affected during convalescence. It seems to be a true reading of natural phenomena that the diseases of short incubation have a prolonged convalescence, and remain long sources of communication, while the diseases which show a long incubation give a quicker convalescence, and a more rapid freedom from danger as a centre of communication of disease. Here there is a practical lesson that cannot well be over-estimated. Keep the cases of short incubation at home. They will infect others and be injured themselves by removal.

In the discussion which followed, the President, Dr. Squire, Dr. Tripe, Mr. Shirley Murphy, Dr. Bate, Dr. Dixon, Dr. Heron, and Dr. Dudfield took part.

Reviews and Notices of Books.

Report on the Scientific Results of the Voyage of H.M.S. "Challenger" during the Years 1873–76. Prepared under the superintendence of Sir C. WYVILLE THOMSON, F.R.S. Zoology. Vol. II. 1881.

THE second volume of the Report of the *Challenger* expedition contains an immense amount of new and valuable information in the departments of Zoology to which it is devoted. The lively interest that is taken in the scientific results of this very important expedition is sufficiently shown by the statement made by authority in *The Times* of the 16th ult., that the sale of the parts already published by Her Majesty's Stationery Office has been so extensive that the number of copies necessary to be reserved to make up even a limited edition of the work in its complete form will allow little if any margin from which persons who begin by purchasing the later volumes can rely upon being able to complete them hereafter with the earlier numbers. The moral therefore is that those who desire to obtain complete copies of this work should at once secure the volumes that have already been issued.

The present volume contains two reports. The first is a report on certain Hydroid, Alcyonarian, and Madreporian Corals, by H. N. Moseley, M.A., F.R.S.; and the second is a report on the Birds collected during the voyage, by Philip Lutley Sclater, M.A.

Mr. Moseley commences his report with a carefully drawn-up description of Milleporidæ in general, and of Millepora nodosa in particular. The hard tissue, by him christened Cœnosteum, consisting of a widely spread basis, rises in a series of projecting, short, irregular tubercles. These present pores on their surface and canals in their interior, occupied by the cœnosarc or soft part of the coral; the cœnosteum and the cœnosarc together constituting the hydrophyton. The growth of the coral commences by the formation of a thin film, which is exactly moulded to the adjacent surface. In homology with this continuous layer other parallel layers are gradually formed, and certain transverse laminæ or tabulæ which divide the cavities of the calicles into a series of chambers, shutting off the living tissue from the abandoned dead structures beneath. The pores of Millepora are occupied by two kinds of zooids. In each system of calicles the central larger one is occupied by a short and broad "gastrozooid," provided with a mouth; whilst the surrounding smaller calicles lodge longer and more slender "dactylozooids," which have no trace of mouth. The gastrozooids are short, thick cylinders, about half a millimetre in height, with a short conical hypostome, and four, five, or six tentacles arranged equidistantly in one whorl just below the extremity of the hypostome. At the summit of the hypostome is the mouth, which in the living expanded animal has a conspicuous glistening white appearance, owing apparently to the presence of large gastric cells around the aperture, which strongly reflect the light. The dactylozooids are about three times the length of the gastrozooids; they are cylindrical and tapering; they have no trace of a mouth, but bear tentacles at irregular intervals from base to summit, the number of tentacles varying from five to twenty; they seldom carry their bodies expanded straight, but usually bent in several curves, and appear to bend over towards their gastrozooid from time to time as if to convey food. When a portion of the coral has been placed living in reagents, it is found, after becoming hardened, to be bristling all over with sheaves of threads shot from the nematocyst around the mouths of the calicles. The body of the zooids, when seen in transverse section, is found to consist of an ectodermal layer of cells, beneath which is a layer of membrane and an internal mass of endodermal cells; their bodies contain muscular fibres arranged longitudinally. The canals and spaces in the calcareous cœnosteum are occupied by a network of soft tissue, which with the external layer of ectoderm constitutes the cœnosarc. Only a thin layer of about 0 5 mm., or one-fiftieth of an inch in thickness, is living. Two forms of nematocysts were observed: One which appears to be confined to Hydrozoa, and not to occur at all in Anthozoa—viz., that in which a bladder-like enlargement of the thread occurs at that part of it which is in immediate proximity to the mouth of the cell, the bladder being armed near its summit by three spines set in one whorl. The other form is large and ovoidal, with a thread beset in part of its length with recurved spines; these also occur in hydroid polypes, but are not of so characteristic a form as the three-spined kind. It is a subject for regret that no trace of generative organs could be detected in connexion with any of the zooids. Mr. Moseley, however, is perfectly satisfied that the Milleporidæ are true hydroids, as maintained by Agassiz in 1859. He is also convinced that the Stylasteridæ, the second great division of the Hydrocorallinæ, are Hydroids, and not Anthozoans, and he gives an elaborate description of the hard and soft parts of the several genera of these animals, which he divides into twelve genera, named respectively, Sporadopora, Pliobothrus, Errina, Distichopora, Labiopora, Spinipora, Allopora, Stylaster, Stenohelia, Conopora, Cryptohelia, and Astylus.

Part II. of Mr. Moseley's report is devoted to the Helioporidæ, Part III. to the Deep-sea Madreporaria. The number of these was comparatively small, but all are described, and the new forms are all shown in woodcuts, and in the plates, which are most beautifully executed, and do great credit to Mr. Moseley's skill in delineation.

The second section of the volume is occupied with a Report on the Birds collected during the voyage of the *Challenger* by Philip Lutley Sclater, which comprises also a report on those collected in the Philippine Islands by the Marquis of Tweeddale, and other reports on the birds collected in special regions by Dr. Fuisch, M. Salvadori, Mr. Forbes, Mr. Saunders, and Mr. Salvin. Mr. Sclater also contributes a list of the eggs collected during the expedition, and there is a short note by Mr. A. H. Garrod on the gizzard and other organs of Carpophaga latrans. Thirty coloured plates illustrate the more important new birds that have been found, some of which are most gorgeously coloured.

A Treatise on Foreign Bodies in Surgical Practice. By ALFRED POULET, M.D., Adjutant Surgeon-Major, Inspector of the School for Military Medicine at Val-de-Grâce. Two Vols. New York: W. Wood and Co. London: Sampson Low and Co. 1880.

THESE volumes are issued as a portion of "Wood's Library of Standard Medical Authors." They are the result of a very great amount of labour on Dr. Poulet's part, and are a valuable storehouse of useful and curious information on a subject from its very nature rich in remarkable details and incidents. Ancient and modern literature in many languages has been ransacked for all kinds of cases of foreign bodies, and anyone desirous of acquainting himself with the history of foreign bodies in any situation will find these volumes a necessary and very valuable help. But having said this much we are not able to speak any further words of praise. It is a wearisome book to read, and every page bears evidence of the author's painful efforts to be very complete, and very systematic, and very theoretical. All extraneous matters that can possibly be dragged in are made to swell the amount of information given; and the author appears not to be able so to group the facts bearing on his subject as to present all their points in their due proportion, and so he seems to us to fail in giving clear pictures of the different states he tries to delineate, and still more do we find wanting precise practical indications for treatment. Indeed we have the impression that the book is the outcome of wide and careful reading—what has been called paste and scissors—not backed up by extensive practical experience. In the preface one of the reasons why the book has been written is stated to be the ignorance of students and young practitioners on the subject of the treatment of foreign bodies. We will not attempt to dispute the fact now and here, but we feel sure no such student would ever think of going to Dr. Poulet's work for help in time of difficulty, for he would soon be lost in the maze of bewildering details. It must form a feature in all college and public scientific libraries, and no doubt it will be often quoted by other writers who will reap advantage from Dr. Poulet's labours.

New Inventions.

DISARTICULATING STETHOSCOPE.

THIS instrument, designed by Dr. Whittaker, is contrived chiefly for convenience in carrying. One half the stem is contained within the other half, the screw-thread keeping it fixed. For use, the smaller tube is unscrewed and applied the reverse way to the larger, and fixed by the screw, forming a stem similar to the ordinary stem of a stethoscope. Fig. 2 represents the ear- and chest-pieces as arranged for carrying; one fits within the other. When required for use, they are separated, and the "fitting" joints enable them to be fixed firmly and instantaneously to their respective ends of the stem, ground accurately to receive them. The chest- and ear-pieces, when arranged for carrying, take up no more room than a medal or a couple of coins, while the stem takes up the same room as an ordinary pencil; both may be carried in the waistcoat-pocket, and never noticed. The advantages will at once be obvious, since it is difficult to conceive an awkwarder instrument than the stethoscope for carrying; and if the instrument can be made to equal the ordinary stethoscope in its acoustic properties, this ingenious device is sure to meet with approval. A comparative trial with this invention shows that (possibly owing to the necessarily flat surface of the chest-piece) in the latter respect it hardly comes up to the awkward but reliable wooden stethoscope. It is made by Hilliard of Glasgow.

THE EXAMINATIONS FOR THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—I am glad to see that the results of the recent examinations at the Royal College of Surgeons of England are of sufficient importance and gravity to demand a leading article in THE LANCET.

With the examinations for the membership you deal fully, the Fellowship Examinations you merely characterise as "peculiar," and dismiss with a very short notice. As a member of the profession deeply interested in all that concerns medical education, I beg to call your further attention to the examinations for the Fellowship, about which "the schools" are just now deeply exercised, and I fear not without some reason. The feeling abroad is, that however well prepared the candidates may be, only a certain proportion are allowed to pass, and that the process of elimination is attended with so much uncertainty that men who have already distinguished themselves as demonstrators of anatomy, senior house-surgeons, &c., frequently "fail to satisfy the examiners," while men of a very inferior status as frequently manage to get through.

When it is remembered, moreover, that each rejection brings a fee of five pounds to the College exchequer, the money question is, to say the least of it, not satisfactory. I venture to think that the fee ought not to be redemanded every time an unfortunate candidate presents himself for re-examination (it is not so, I believe, at the London University examinations), and that a severe and very searching examination might be possible, with results less at variance with the judgments of those who, having known the candidates and their work for long periods, are not likely to err in their opinions regarding them.

The present uncertainties and peculiarities which lead our best men to expect one or more mishaps almost as a matter of course, and to accept a pass, if it falls to their lot, as a happy piece of luck, will not tend to raise the standard of the examination, or add to the dignity and value of the Fellowship of the Royal College of Surgeons of England.

I am, Sir, yours obediently,

June, 1881. CHIRURGUS.

⁂ If our correspondent will consult the last balance-sheet of the College, he will find that the two examinations for the Fellowship entailed, last year, a total loss of £217 18*s.* 4*d.*—ED. L.

THE LANCET.

LONDON: SATURDAY, JUNE 18, 1881.

IT is not easy to put aside all doubts as to the expediency of the publication of Dr. BUCHANAN'S Memorandum on the estimated relative incidence of the present epidemic of small-pox upon the vaccinated and unvaccinated in the London population, although it must be freely admitted that the statistics are dealt with in an effective, if not an entirely novel manner. Supposing that the small class which is opposed to vaccination were open to conviction through the medium of arguments based upon statistics, we might fairly expect that the publication of this Memorandum would have some effect upon this opposition. Those, however, who know best the weapons used by the leading anti-vaccinationists, and the method of their use, will find it difficult to be sanguine as to the effect of Dr. BUCHANAN'S Memorandum. To the believers in vaccination, and in the expediency of compulsory vaccination, the Memorandum will be readily accepted as a clear and logical arrangement of facts which afford the strongest evidence of the protective power of vaccination against small-pox fatality.

The Memorandum is based entirely upon the 1532 fatal cases of small-pox registered in London during the fifty-two weeks ending 28th May last, and upon the information respecting the vaccination or non-vaccination of these cases, recorded by certifying medical practitioners, and published by the Registrar-General in his Weekly Return. This information was unfortunately not given in 570, or 37 per cent., of the 1532 fatal cases; and Dr. BUCHANAN has had to base his calculations and conclusions on the 962 cases in which the information was furnished, and of necessity to assume that the proportion of vaccinated and unvaccinated among the "not stated" cases was the same as that found to prevail among the stated cases. It is this very assumption on the part of Dr. FARR and the Registrar-General which has, during the past ten years, subjected them to the virulent abuse of anti-vaccinationists. Therefore, while we fully accept as trustworthy the grounds, so well explained by Dr. BUCHANAN, for making this assumption, we fail to see the expediency of its reassertion. When we come to the second stage of Dr. BUCHANAN'S calculations, we are still upon debateable ground—namely, the estimation of the numbers of vaccinated and of unvaccinated persons in the London population. On the basis of an estimate which has been frequently used, and as frequently attacked, it is calculated that the London population contains only 190,000 unvaccinated persons. Dr. BUCHANAN further assumes that 105,000 of this number are of persons under twenty years of age, and only 41,000 of children under five years of age. Anti-vaccinationsts have urged again and again that the estimates of the numbers of the unvaccinated are far too low, and we cannot feel sanguine as to their acceptance of them now. However, when Dr. BUCHANAN shows that during the past year the death-rate per million from small-pox in London has been only 90 among the vaccinated, against 3350 among the unvaccinated, it is impossible to deny that the figures, after full allowance for possible errors of estimate, afford overwhelming testimony in favour of vaccination. Similar statistics, based upon similar calculations, show that under five years of age the proportional mortality from small-pox in the past year was 40½ per million among the vaccinated and 5950 among the unvaccinated class. These figures, however, understate the true relative proportion of mortality from small-pox among these two classes of the population, as among infants under one year of age in epidemic seasons many are vaccinated while under the influence of infection, and if fatal small-pox afterwards occur the cases are improperly described as vaccinated. It would have been better to have left the infant population out of the calculation, and to have dealt with children aged one year and under five. It is not surprising to find that the protective power of vaccination, tested by Dr. BUCHANAN'S figures, decreases at more advanced ages. However, among all persons aged under twenty years, the relative mortality is shown to be 61 and 4520 per million of the vaccinated and unvaccinated classes respectively. Considering that one of the important features of recent small-pox epidemics is the large and increasing proportion of adults, we regret that Dr. BUCHANAN has not dealt in his Memorandum with the relative mortality during last year among persons aged upwards of twenty years. There is undoubted difficulty in the way of estimating the numbers of vaccinated and unvaccinated adults in the population; from Dr. BUCHANAN'S figures, however, he appears to estimate that there are only 85,000 unvaccinated adults in London. We rather doubt the probability of there being in London fewer unvaccinated adults than unvaccinated persons under twenty years of age; but accepting these figures, it follows that during last year the proportional rate of mortality among adults was respectively 111 and 1906 per million living of each class.

These facts, after full allowance for all errors in the estimates used for the calculations, afford grounds for the strongest special pleading in favour of vaccination. We doubt, however, the expediency of any such special pleading. *It is beyond dispute that efficient infant vaccination, followed by efficient revaccination at adolescence, practically confer immunity from fatal small-pox.* It is wiser, we think, for the Department having the control of vaccination simply to take its stand upon this ground, and to accept the recent small-pox epidemic in London, so far as regards the deaths of children, as evidence of a failure of the vaccination system as at present carried out. Vaccination requires no defence or apology at the hands of its administrators, and this Memorandum suggests an admission that the President of the Local Government Board considered vaccination itself to be on its trial, instead of the system and efficiency of vaccination administration.

From our point of view the most satisfactory part of Dr. BUCHANAN'S Memorandum is that in which he says, "I am now engaged, with Dr. STEVENS' assistance, in some inquiries into the relative protective influence of one and another sort of vaccination." With regard to the ninety-four registered cases of fatal small-pox after vaccination in London during the past year, under twenty years of age, it is of the first importance to have some information. Were those ninety-four young persons ever really vaccinated, and if so were the vaccinations performed by public or private vaccinators? It is no secret that much of the so-called vaccination in London and elsewhere, although certified as successful, is really of none effect. It is this which tends to discredit vaccination, and it is this which calls for searching investigation and exposure. According to the most recent official returns little more than six per cent. of the children in Bethnal-green escape successful vaccination; and yet it appears from a report based upon a house-to-house visitation made by the vaccination officer of that parish during the past three weeks, that out of a total of 6018 children under fourteen years of age, respecting whom inquiries had been made, no less than *828, or 13·8 per cent.*, were *unvaccinated.* Such a failure of our vaccination system calls for explanation, and at the same time throws considerable light upon the cause of the recent fatal prevalence of small-pox in East London, especially in Bethnal-green and Shoreditch.

We have fortunately now arrived at the season when the small-pox epidemic in London will inevitably subside; indeed the decline has already set in. Before the season for its revival comes round it is not unreasonable to hope that we may know more of the causes of the comparative failure of the vaccination system in London, in order that measures may be taken for increasing its efficiency.

◆

TO the credit of our common philanthropy, Hospital Sunday is as much an institution now in London as hospitals themselves are. Towards the close of 1872 it was proposed that collections for the benefit of hospitals and dispensaries in London should be annually made on one Sunday in the year at all places of worship. THE LANCET was the original promoter of the movement, and has supported it with signal success. The prosperity of the enterprise has varied since then with the varying prosperity of the country, but there is good reason to believe that the institution itself, and the Council by which it is carried on, enjoy increasingly, year by year, the confidence of the churches. In 1880 the largest sum yet raised for the purpose was collected. Last year we were careful to go into some detail to stimulate sympathy with sickness; and we have the pleasure to remember that our statements were extensively read, and that the resulting collection was the largest in any year since the foundation of Hospital Sunday. We will not repeat our arguments for a good collection on Sunday next. There is no doubt that it will be most acceptable to both the hospitals and dispensaries. Depression of trade, or something else, still continues to affect hospital finances so as to make the administration of hospitals and dispensaries anxious work. It is within our knowledge that many of them are only kept going by selling out scanty stock, that gives little sense of security and comfort to those who are responsible. Nearly every hospital report that we take up has some such burden to disclose. There are signs of revival of trade according to the admission of critics. It is certain that there is trade enough to supply funds to enable the committees to fill every bed in every London hospital, and pay off the debt of every London hospital and dispensary. With a little more charity and consideration of the case of the inmates of our hospitals, the last collection might be easily exceeded by £10,000. We suggested last year that ministers should visit the hospitals on the Saturday preceding the day of collection. We are sure of two things: first, that they would be well received; and, secondly, that, in the sight of so much sickness and of the many "lenient arts" by which it is sought to mitigate it, they would find the truest inspiration for an appeal to Christian charity. The hospitals were never more worthy of benevolent help than they are to-day. They never did more good or less harm. They never were administered more wisely or economically, or with better precautions against abuse. It is not the least claim of Hospital Sunday that it has brought the hospitals and the churches, irrespective of creed, into close contact, and made hospital relief and help much more accessible to really deserving cases.

◆

SINCE VIERORDT first introduced the method of counting the corpuscles in a given volume of blood as a source of information regarding its pathological states, several observers have applied the method to the investigation of the effect of loss of blood on that which remains in the circulation. The latest, and one of the most valuable, of these investigations has been carried out at Heidelberg by an American physician, Dr. LYON.

Before trustworthy conclusions could be drawn from the results of experiments in producing traumatic anæmia, it was necessary to ascertain the spontaneous variations in the corpuscular richness of the blood. Observations for seven days on a dog, and for twenty-one days on himself, led Dr. LYON to the conclusion that the variations in a single day are so slight that they may be disregarded, but that during a series of days variations do occur which cannot be accredited to errors of observation. In the dog there was a steady slight decrease, amounting to about 6 per cent.; in the experimenter there was a gradual increase in the number of corpuscles per cubic millimetre, amounting to about 2 per cent. It is of great importance that the occurrence of such variations should not be lost sight of in drawing inferences from observations in pathological conditions. The observations on the effect of hæmorrhage were made upon dogs which were fed once daily, and the corpuscles were counted just before the daily feeding. At least 5000 red and 200 white were counted on each numeration. Previous experiments had shown that the error in observation, if 5000 corpuscles are counted, does not amount to more than 1 per cent., and if 200 are counted it amounts to about 5 per cent., but in taking the blood from the ear of an animal it was probable that the amount of error would be nearly twice this. The hæmorrhage was effected in most cases by opening the jugular or some other large vein, the animals being at the time under the influence of morphia. The amount of blood taken varied from 700 to 1350 cubic centimetres, being from 3·5 to 4·5 per cent. of the body weight. Observations made during and directly after the hæmorrhage showed an immediate diminution in the corpuscular richness of the blood, which agrees with the result obtained by other observers. The fall is, however, far greater in the case of guinea-pigs than in dogs. In the latter, even a very large hæmorrhage (equal to 4 per cent. of the body weight) does not reduce the number of corpuscles below 80 per cent. of the normal, while in the former a loss of blood amounting to only

2 per cent. of the body weight has reduced the number almost to one-half of the normal. A possible explanation of this may be found in some observations of VON LESSER, who found that the variations in the amount of hæmoglobin in the blood, after slight and considerable hæmorrhages, corresponded closely to the variations in the blood-pressure. The greater the fall in the blood-pressure, the greater is the diminution in the amount of hæmoglobin. It seems necessary to assume that in the guinea-pigs there is a greater fall in blood-pressure than in dogs, and a correspondingly greater quantity of serum passes into the blood from the tissues.

The observations corroborate the statements of HUNERFAUTH and BUNTZEN that the proportion of corpuscles in the blood falls still further during the first days after the loss of blood, and only regains the normal at a later period. The time at which the minimum is reached varies from a few hours to several days. It is roughly proportioned to the amount of blood lost, the interval being the longer the greater is the loss; but this relation, although generally to be observed, is not exact. The normal—i.e., the amount of corpuscles before the hæmorrhage—is usually regained in rather less than three weeks after the operation.

A very different effect is, however, manifested by the white corpuscles. In a few hours, and for a few days after the hæmorrhage, their number per cubic millimetre of blood is found to exceed considerably the number previous to the operation. The maximum is usually attained within a few hours, rarely not until the next day. It may amount at the maximum to two, four, or even five times the normal average. The duration of the excess is about four days, and then it gradually passes away. This change of the two kinds of corpuscles in different directions explains the great alteration in their relative proportion which has been known, since the time of REMAK, to follow loss of blood.

The attempt to ascertain the facts in the case of man is beset with many difficulties. Alike in the case of injuries and operations, it is difficult or impossible to ascertain exactly the amount of blood lost, and it is equally difficult to ascertain the normal state of the blood in the individual for purposes of comparison. Some interesting facts observed with great care by Dr. LYON show clearly, however, that the same effect occurs in man as in the dog. The white corpuscles are immediately increased in number, and this increase lasts for several days. The diminution in the number of red corpuscles also lasts for several days, and the minimum occurs sooner the slighter the hæmorrhage. In one case, in which great loss of blood occurred, on an attempt to remove a fibroma from the posterior nares, the pulse could scarcely be felt, and artificial respiration was needed; the minimum amounted to a reduction of one-half the corpuscular richness of the blood before the operation, and this was reached, as in the case of animals, on the fourth day. The length of time needed for the return of the blood to the normal varies greatly in different cases, being, in some, increased by secondary hæmorrhage, as in the case just mentioned. In others the increase in corpuscles was apparently accelerated by the occurrence of diarrhœa, which, as BROUARDEL has shown, renders the number of corpuscles, in a given volume of the blood, greater, no doubt, by withdrawing some of the serum. In some cases the fall which was observed was actually greater than the amount of blood taken would account for, and for these cases the explanation is offered that the phenomenon is really the result of the effect of the small hæmorrhage on the blood-pressure.

◆

PROFESSOR STRUTHERS is as much entitled to be heard as most men on the feeling in favour of having some kind of Joint Examination Board. His letter of last week will be read with interest by a large number of persons, in and out of the profession, who are studying the present state of the law of Medical Registration, and watching the action of the Royal Commission charged to investigate the working of that and other parts of the Medical Act of 1858. There is something captivating in the very simplicity of the problem of Medical Reform, as it is presented in Professor STRUTHERS' letter. The feeling in favour of it is located in England; it has its "just" root in the state of the law which permits registration on a partial qualification, and in the desire to see the Colleges of Physicians and Surgeons form a joint examination. Were such a junction formed voluntarily and a Registration Act passed requiring "a complete qualification before registration, the licensing difficulty would be virtually at an end." The Corporations are all anxious to form such boards, and to discontinue their separate action in granting diplomas, but mutual distrust hinders. Edinburgh has set the good example of a joint examination, but there is still the weak point of separate action and a one-sided diploma, and she fears to discontinue this lest London should not follow suit. And as Edinburgh distrusts London, London distrusts Edinburgh, and each goes on its own way.

There is some truth in this mode of putting the question; but it has one fatal defect—it is a thoroughly inadequate statement of a large and complicated evil. It has been a favourite representation of our Scotch friends that all that was wanted was to stop single qualifications being granted, and to make only complete or double qualifications registrable. But a very little consideration will convince our readers, and, we would fain hope, convince Dr. STRUTHERS, that his simple remedy bears no proportion to the evil to be remedied. The real evil is not now so much in the existence of one-sided examinations, for under the influence of public opinion examinations have become far less one-sided than they used to be, and embrace, as a rule, all branches of general practice. It is in the inequality of the examinations. The Corporations themselves disparage each other. We shall not decide which Corporation has the better right to be satisfied with its own examination, and to disparage that of the sister college in the other division of the kingdom. But there is inequality. Men rejected at one Board over and over again go confidently to another, and come back with a title to registration which had been denied them at the first institution to which they applied. We shall not attempt to prove that this inequality exists; it is notorious. If this is true of the lowest qualifications, it is still more true of the highest ones. So that whereas a Fellowship of one college must be gained by long study and the severest examinations, that of another may be had practically for money. Then, again, not only are the examinations for corresponding qualifications unequal, but the diploma-granting bodies are, on all hands, allowed to be too numerous. When diplomas had only a local value numerous and local attesting bodies might be required. But now, when a diploma granted in one division of the kingdom qualifies in all, and in all parts of the empire, imperial precautions to secure equality should be taken. They are not even hinted at in Dr. STRUTHERS' letter. The very number of the bodies claiming to enter into conjoint schemes makes such schemes dear and difficult to work, and we shall be grievously disappointed if the Royal Commission does not see this. We are not concerned to deny the honourable spirit which actuates the leaders of the Corporations. Corporations are all "honourable," but there are too many of them, and their mutual competition has not always been honourable to the profession or advantageous to the public. Professor STRUTHERS' representation is surely inadequate in another point. It locates the dissatisfaction with the existing system "in England." We believe it to be far more general. It certainly obtains largely in Ireland and, we believe, in Scotland too. Scotland can well afford to favour a thorough reform. In her universities she educates English practitioners on a large scale, and she is indeed deeply interested in every improvement of the tests by which medical education is proved. Her University system and interests are well represented on the Royal Commission by Professor TURNER; but we shall be surprised if he fails to recognise that the interest of Scotland—of her universities at least, if not of her Corporations—is to say, as Professor GAIRDNER virtually said before the Select Committee, "give us legislation that will satisfy a General Medical Council that our education is good and that our examinations are efficient." Professor STRUTHERS seems to think the institution of voluntary Conjoint Boards by the Colleges of Surgeons and Physicians will leave nothing to be done by the Royal Commission. We differ from him. It is too late now to arrest an investigation into arrangements which are costly, complicated, inefficient, and altogether out of time.

◆

THE subject of lunacy law reform would seem to have been again shelved by the second reading of Mr. DILLWYN'S Bill. This is to be regretted, although, perhaps, the result was inevitable. If the Government had rejected the measure the agitation would have been increased rather than appeased by the opposition offered. What has happened is a hollow compromise, a concession sulkily made to the effect that the Bill should be read a second time on the understanding that the Government would not be further troubled in the matter. A hope prevails among distinguished personages and in official circles, from the Lord Chancellor, the Home Secretary, the Commissioners in Lunacy, the proprietors of private asylums, down to the classes or individuals supposed to be interested in perpetuating the existing state of matters, that now the member for Swansea has had his say the question will rest and its promoters be silenced. It is not worth while to discuss the probabilities that this hope may be realised. Its fruition would not surprise us. There is no more successful mode of dealing with a question of this character than that adopted. Mr. COURTNEY was put up to champion the worn-out policy of resistance, and very awkwardly did that gentleman acquit himself of the task. The Home Secretary broached the alternative method of getting rid of the question, albeit, with less than his usual grace and sagacity, and the measure fell to the ground; and that was the end which, so far as the Government was concerned, it was desired to compass.

Mr. DILLWYN is probably satisfied with the result he has obtained. He has embodied in the re-amended draft of his Bill, the one now formally before the House of Commons, some half-dozen of the proposals which have from time to time been made in these columns: for example, the purchase of private asylums by the creation of State bonds, the requirement of an *official* medical signature to every certificate, the creation of a local inspectorship, with a system of printed reports to be made directly to the Commissioners in Lunacy, the establishment of a practical supervision of cases by an official who will know the patients personally, and a provision by which the insane can be promptly placed under treatment without the delay and excitement caused by formal certifying, an examination being made by an independent officer *after* the patient has been removed to an asylum. In so far as the Bill which has now been read a second time embodies these reforms, we, of course, approve it, though we shall hereafter—if it should be revived—have something to say as to the manner in which the proposals adopted agree or disagree with other parts of the Bill. Before the introduction of the provisions taken from the columns of THE LANCET, we were only able to give the measure a very guarded support. Our feeling towards it is still only so far favourable as it may be susceptible of modification to meet our views. The subject of lunacy law reform is one which we have urged on the consideration of the Legislature and the profession continually for many years past; and we shall never grow weary of pressing it until private asylums are placed on an entirely new footing, being in fact, if not in name, converted into public institutions, their proprietors no longer deriving direct benefit from the retention of patients, and their executive staff being armed with public and official, instead of private and personal, authority over their inmates, and until measures are taken to prevent the sane but excitable from being hurried into asylums, and to secure that the convalescent may find an easy way of escape. In short, we cannot, so far as our appeal is concerned, allow the matter to drop until a large and liberal measure of reform has been passed—whether by some enlightened Government or an enterprising member we care not, so that the law be amended as justice and public safety demand.

We discussed the principal clauses of Mr. DILLWYN'S Bill at some length on the 5th of February last, and there is nothing further to say on the subject at the present moment. The comments which have appeared in the press on the measure, and the brief discussion which was raised on the second reading, point almost unanimously to the conclusion that the member for Swansea would have done better to adopt our proposals in their entirety than in part only. The *Saturday Review* and other thoughtful contemporaries have indicated the defects of the Bill as it stands, and these are, with scarcely an exception, due to the omission of some integral part of our proposal. For example, the *Saturday Review* says:—

"What is really needed—so long as private asylums are allowed to exist—is that every alleged lunatic confined in them shall be personally examined, at reasonably short intervals, by a competent Medical Inspector, who shall in each case make an order, either for the discharge or for the continued confinement of the patient, according to the opinion he has formed of his mental state at the time. This Medical Inspector should be an officer of the Government, and so be above any possibility of being influenced either by the proprietor of the asylum or by the friends of the patient."

This is but a paraphrase of the following specific suggestion for dealing with the cases of patients on removal to an asylum. "Within eighteen hours of admission, notice should be sent to the office of the Commissioners in Lunacy, and an order be issued from the Board to an *official* medical examiner, duly appointed by the Board, and not engaged in private practice, either as medical attendant or medical witness, who should at once proceed to the asylum, and report *directly to the Commissioners* as to the nature of the case, and the expediency of detaining it. If residence in the asylum were deemed desirable, the Commissioners could make an order to that effect—such order to have the force of a certificate of insanity—and by the visits of these inspectors provide for *the continuous watching of the case.* In this way, for twelve months at least, every new patient would be *kept under official observation*, a measure which could scarcely fail to exert a satisfactory influence on the treatment." The parallelism of thought, if not the origin of the suggestion, is obvious. In short, the Bill is weak where our proposals were discarded, and strong only where they have been adopted. We shall look with interest to the form in which this measure may survive, or be introduced at another opportunity. If its author is well-advised he will embody the scheme we have laid before the public without modification or abatement.

THE International Congress dates from a meeting of the French Medical Association in Bordeaux in 1865. The idea there ventilated was first realised in Paris in 1867, under the presidency of M. BOUILLAUD, during the time of the International Exhibition. The next meeting was held in Florence in 1869, and subsequently the Congress assembled in Vienna (1873), in Brussels (1875), in Geneva (1877), and in Amsterdam (1879). An International Medical Congress held in Philadelphia at the time of the Great Exhibition there, was not one of this series. At each of the meetings in the continental capitals large numbers of delegates and members attended. But the meeting shortly to be held in London is looked forward to by those most interested in the Congress as marking a new era in its history, and as a venture of a far bolder character. Hitherto the business has been transacted in one or, at most, two languages. In the London meeting three languages will be spoken, and while before only the attendants at one meeting had invitations addressed to them for the next, the London Executive have issued an invitation in his own language to nearly every medical man in the world. An effort has thus been made to ensure its being in fact, and not in name only, an International Congress. It is a matter of just pride to us that such a change in the scope of the Congress should be connected with its meeting in London, which we call the metropolis of the world. And, although we have not the right to assume superiority in matters medical and scientific, we have yet such a history, with its records of HUNTER, HARVEY, JENNER, and the BELLS, and in more recent times of COOPER, LISTON, SYME, SIMPSON, BRIGHT, ADDISON, GRAVES, STOKES, and FERGUSSON, not to mention many others, that, whether on the ground of great historic discoveries, or on that of successful practice of our art, we can bear comparison with any country, and with no lack of propriety ask the medical profession of the world to meet us in scientific discussion. In America and all the countries of Europe great interest has been awakened in the ensuing meeting, and very high expectations are being held of its importance and usefulness. Thus early more than 300 foreigners have intimated their intention of attending, including men of world-wide reputation, such as ALBANESE, ALBERTIS, ANGELUCCI, BILLINGS, BROWN, BARDELEBEN, BIGELOW, CHARCOT, CHAUVEAU, DONDERS, ESMARCH, HALLÉ, HARDY, HEBRA, KÜSTER, LANGENBECK, SNELLEN, VERNEUIL, and VOLKMANN. Several foreign Governments and learned Societies have expressed their desire to send representatives to report on the meeting. The medical profession in England has already to a large extent shown its interest by monetary subscriptions and by the labours of the secretaries and executive officials of the various sections and committees. But it rests with the whole constituency to make the Congress such a thorough success as it ought to be. And every one must feel, apart from other perhaps more worthy motives, that national pride and generous hospitality alike compel us each to do his utmost to make not only the visit of our foreign friends pleasant, but the meeting of so many leaders in medical science useful to the world at large. Intelligent interest and sympathy will greatly aid the executive, and will enable them to carry to a successful issue schemes which otherwise must prove futile. We have no doubt that this support will be forthcoming. Some, however, may ask, What possible good can come out of the Congress?—whether it will not be a very busy week, with crowded meetings at which the business will be hurried over, followed by pleasant entertainments in the evening; in fact, an excuse for a holiday with a semblance of work? No doubt some Congresses are such and but little else. But surely more is to be hoped for from our August gathering. To meet face to face those who are now but celebrated names to many of us, and to form friendships with fellow-workers in other lands, will not only add a zest to our own work, but will greatly enlarge our interest in that of others. With the rapid strides science and the medical art are making in almost all countries, it becomes impossible for practitioners, especially those who are themselves the most active, to keep *au courant* with all the details of the general advance, and it is a labour of a life to acquire thoroughly the knowledge that has been and still is being accumulated on even the subdivisions that are now universally made. But when the leading workers from all lands meet together, knowledge is very rapidly imparted and interchanged; views that perhaps would never otherwise reach us are expressed, and opinions well cherished and supported may quickly receive their quietus. It must be evident to all that no one really desirous of learning may not in the one short week gain large stores of information from those best qualified to give it—first hand, not filtered through text-books and reviews. Among the large number of papers that will be read we may certainly count upon many of permanent value; and the more formal addresses to be delivered by Sir JAMES PAGET, MAURICE RAYNAUD, Dr. BILLINGS, Professor VOLKMANN, and Professor HUXLEY, are each and all of them sure to be worthy of the great occasions on which they will be delivered, and lasting memorials to the scientific fame of the orators. It has been well said that a visitor to Rome sees in that unrivalled city only what he is already acquainted with; so those who look upon Congresses as holidays will find this particular one a holiday of unequalled interest, while those who come to it desiring to learn will have an unexampled opportunity of doing so. Indeed it is too obvious to require any argument that a meeting of several hundreds of medical men, to a large extent unacquainted with each other's opinions and practice, must be productive of most valuable results.

Annotations.

"Ne quid nimis."

COLLEGE ELECTIONS.

THE time for nominating candidates for seats in the Council of the Royal College of Surgeons at the annual meeting to be held on Thursday, the 7th prox., expired on Monday last, the 13th inst. The following gentlemen have been nominated:—Sir James Paget and Mr. Walton for re-election; and the following for election in the order of seniority: Mr. John Whitaker Hulke, May 23rd, 1857; Mr. John Croft, Nov. 24th, 1859; Mr. Christopher Heath, May 31st, 1860; Mr. Reginald Harrison, Dec. 13th, 1866. The new candidates are all Fellows of the College by examination. Mr. Hulke is also a Fellow of the Royal Society, surgeon to the Middlesex Hospital, and obtained the Jacksonian prize, in the year 1859, for his essay on the morbid changes of the retina, as seen in the eye of the living person, and after removal from the body, together with the symptoms associated with the several morbid conditions; he is, besides, a member of the Court of Examiners. Mr. John Croft is surgeon to, and lecturer on surgery at, St. Thomas's Hospital, and late examiner in surgery at the Royal College of Physicians. Mr. Christopher Heath is surgeon to University College Hospital, Holme professor of clinical surgery in University College, late chairman of the Board of Examiners of the College of Surgeons, and, like Mr. Hulke, a Jacksonian prizeman for an essay on injuries and diseases of the jaws, including those of the antrum, with the treatment by operation or otherwise. Mr. Reginald Harrison is surgeon to the Liverpool Royal Infirmary. Mr. Sydney Jones is not a candidate, as we incorrectly stated last week. There are, therefore, seven candidates for the three vacant seats. No doubt can be entertained about the re-election of Sir James Paget, who has served the College well for many years. For the two other seats there will be the keenest competition. It is commonly felt that two, at least, of the candidates, are of conspicuous merit, and possess exceptional claims upon the suffrages of the Fellows. Both Mr. Hulke and Mr. Heath have rendered long and important services to the College as examiners, and they have both had extended experience as teachers in large metropolitan schools. It is satisfactory to find that not one of the candidates this year possesses an overwhelming reputation as an exponent or practitioner of a particular department of surgery. A story is current—it must refer to a long past epoch—of a gentleman, who had been elected a member of the Council solely on his reputation as a champion of special pathological doctrines, but took so little interest in the affairs of the College and attended so few meetings of the Council, that he was unable at the end of his first year to give the names of the president and vice-presidents of the College. Such candidates are out of date now. The affairs of the College are of growing importance, and need the close and unremitting attention of all the members of its Council, whose chief qualifications should be personal experience of all matters relating to medical education and capacity and inclination to deal fairly and honestly with all questions of medical reform. It may be added that this year red pencils will be used instead of *pen and ink* to mark the voting papers on the day of election.

PROFESSOR SKODA.

WITH the lamented death, on the 13th inst., of Joseph Skoda, after a prolonged and painful illness, the last of the great men whose names made Vienna famous a generation ago, has passed away. Oppolzer, Rokitansky, Hebra, and now Skoda, have departed—men who, devoting their lives to scientific medicine, may be said to have created a school which had hardly its equal at the time. Doubtless the University of Vienna will continue to hold high rank in medical education and research, but it can never be higher than it was when strangers flocked from all parts to sit at the feet of that famous band of masters. The records of the lives of such teachers are not usually eventful; they are to be found in the memories of those who have learned of them and loved them. Skoda was no exception to this. Born at Pilson, in Bohemia, on Dec. 10th, 1805, he began to study medicine at Vienna when twenty years old. He received the doctor's degree in 1831, and returned to Bohemia to practise. He was destined, however, for a wider sphere, and after doing good work in his native country during a cholera epidemic, he returned to Vienna in 1833, and was appointed second physician to the Allgemeine Krankenhaus. About fifteen years before Laennec had introduced auscultation to the medical world attention was being ardently fixed upon this method, and exaggerated ideas were formed of its scope. The kindred subject of percussion as applied to the physical diagnosis of thoracic disease had, more than a century before (viz., in 1716), been discovered by Auenbrugger in Vienna itself, but had received little attention until it was taken up by Corvisart in 1808. To the study of these subjects, in which he had been instructed by Heine and Gutbrod, young Skoda devoted himself with ardour, and in 1839 published the first edition of his famous "Abhandlung über Percussion und Auskultation"—a work which was well received on all sides, passed through many editions (the last edition, the sixth, was published in 1864), and was translated (fourth edition) into our language by Dr. Markham in 1853. In this work—considering the circumstances under which it was written, when many unwarrantable and extravagant doctrines as to the interpretation to be placed upon physical signs were in vogue, and when explanations more or less fanciful were being given to account for auscultatory phenomena—Skoda showed the first qualities of a scientific mind. He was not sparing in his criticism of some of Laennec's assumptions, and showed the utter fallacy of Piorry's pretensions; but he gave his reasons where he dissented, and endeavoured to explain all the phenomena upon the known laws of sound. The influence of Skoda's teaching has been very wide; and he would have been the first to resent any imputation of disloyalty to Laennec, for he served by his own expositions to enhance the fame of the discoverer of auscultation. In the present day these teachings, having undergone many modifications, form the essential foundation of our knowledge; and, as a testimony that in the land of Laennec the merits of the Vienna physician were well recognised, we have the "bruit skodique," familiar to all auscultators in the subtympanitic note elicited on percussion over the compressed lung; and here we use the term "skodic resonance" with equal significance. In his preface to the translation of the work Dr. Markham says: "I would almost venture to assert that it is the most valuable treatise on auscultation which has appeared since the time of Laennec; it contains a philosophic investigation of many of the leading facts connected with the study of auscultation and percussion, and is something more than a mere manual. The reader feels that he is in the hands of a deep and original thinker, and of a most cautious and a clear-seeing observer—of one, indeed, who has had vast experience, and who manifests the rare quality of a will and a power to subject theory to the results of practice and experiment." This is not the place to show how many of Skoda's doctrines have stood the test of time. Some of them have been abandoned or modified—e.g., his theory of "consonance," and his view that both sounds of the heart were produced in the ventricles, aorta, and pulmonary artery severally (a view which Stokes also held); also his denial that muscular contraction could produce a sound. It is enough to testify that his teaching gave an impulse to the study of physical diagnosis, which continues to be felt even to this day. In 1835 Skoda commenced his courses of practical instruction in the subject he had chosen for his life-study, and in 1840 was appointed physician to the division of Chest Diseases in the great Vienna Hospital, becoming in the following year (1841) physician in chief. In 1846 he was appointed Professor of Clinical Medicine, which he held to old age, resigning the office eight years ago; and in the performance of the duties of the office he enhanced a reputation already high, and added in no small degree to the fame of the Vienna school. Contributions on clinical and pathological subjects appeared from time to time in medical journals, but he does not seem to have written much—no larger work, indeed, than the treatise above-mentioned appearing from his pen. He preferred to trust to the influence of his practical example spread over many generations of students rather than to the medium of literature as the means of obtaining fame; and he has died in the knowledge that his memory will be treasured by numberless personal pupils. About six years ago, on the occasion of attaining his seventieth year—when even then his strength was failing—he received the congratulations of delegates from all the learned bodies in Vienna. A medal was "struck to commemorate the event; and seldom have professors and students been so unanimous in paying respect to the man who, many years ago, commenced by his work and lectures to impress the world with his complete familiarity with all matters regarding internal disease, especially complaints of the chest." (THE LANCET, Jan. 1st, 1876.) The final years of his life were spent in lingering pain; and in closing this imperfect notice it may be well to repeat the eloquent words of Dr. West, when speaking of the death of Rokitansky, in his presidential address to the Royal Medical and Chirurgical Society in 1879. He said, "At the grave there befel an incident of most touching pathos. The dying Skoda had himself lifted from his bed of anguish and brought in his carriage to the graveyard, where he sat watching the last of the friend whom he had loved all life long. And as he watched he envied him the great rest which that friend had found, while bodily suffering wrung from him the cry, 'I cannot die, and yet is my pain no less than his.' Skoda still lives and still suffers. We can form for him, whose services, in a different department of our art, were scarcely less eminent than Rokitanksy's, no better wish than this, that the lesson which pain was meant to teach was well learnt; he too may enter into rest." At last the time has come; he has been released from his long suffering, and with his death the last link between the present and the past of the Vienna school has been severed.

NAVAL MEDICAL DEPARTMENT.

AFTER a lapse of nearly two months the Admiralty Instructions on the Order in Council reorganising the Medica Department of the Navy have been issued. For the most part they consist of a mere republication of the Orders of April 1st, which we noticed fully when promulgated (THE LANCET, April 16th, 1881). On a few points only they differ; and the first we notice is, that when a surgeon's promotion to the rank of staff-surgeon has been retarded by his failing to pass the qualifying examination, he is to be granted, when he does pass it, the seniority he would have enjoyed had he been successful in the first instance; but he is to reckon service for increase of pay and half-pay only from the date of passing. It is stated, however, that when the delay in passing has been due to unavoidable circumstances "special consideration will be given." Again, it is provided that increased rates of pay dependent on length of service are not to be paid until receipt of the requisite authority from the Accountant-General of the Navy. This, we presume, is necessary to admit of the claim for increase being verified, and cannot be a subject of complaint unless undue delay occurs in the transmission of the requisite authority. It is stated that applications from officers not entitled to retire or withdraw, to resign their commissions, will receive every consideration. Some assurance of this nature was necessary, as we have heard of medical officers being refused this permission within the last few years, thus establishing a species of compulsory service. Retired officers are promised "special consideration, as regards appointments on shore, connected with the Admiralty, now filled by civilians." Although Mr. Trevelyan stated in the House that it had been determined to frame the new regulations for the navy on the principles laid down in the report of the committee on which the recent changes in the Army Medical Service had been based, he has omitted to follow the important precedent, established by Lord Cranbrook, of granting compensation to those senior officers who are placed on half-pay at fifty-five instead of sixty years of age. A careful consideration of the provisions of the Warrant, as modified by these instructions, has failed to change the opinion we expressed when it was promulgated, that it will scarcely prove successful in inducing well qualified candidates to come forward in sufficient numbers to fill up vacancies. We do not expect that the teachers in the medical schools will consider the conditions of the Warrant so satisfactory as to induce them to recommend their students to join the Naval Service, nor that the students will be disposed to do so when the Army and Indian Medical Services are so much more attractive. The removal of the medical school for naval surgeons from Netley is a very serious drawback; the retention of the examination prior to promotion, which has been abolished in the army, will prove most unpopular; and the absence of any assurance that the rules regarding choice of cabins will in future be carried out cannot fail to keep up the feeling of uncertainty and consequent dissatisfaction which has been long prevalent in the service on that subject.

ORANGE-COLOURED PUS.

THE common variations in the colour of pus are readily and in all probability quite correctly explained by admixture with various secretions, such as the bile, coloured elements of the inflamed tissues themselves, as the pigment of the bronchial glands, or with minute or larger quantities of the colouring matter of the blood. But there are certain other cases of which this is hardly a sufficient explanation, such as those of blue suppuration (to which Dr. Gibb drew special attention some years ago, and which he attributed to the presence of cyanide of iron) and of orange-coloured pus. Surgeons who practise Listerism will be quite familiar with a bright yellow colouration of the saturated carbolic gauze; we do not, however, refer to that, but to a condition in which, without any special external application, orange-coloured pus is *secreted.* The cases are by no means common, and the peculiar colour is usually of only short duration. M. Verneuil, in referring to his experience of them, states in the *Archiv. Gén.* that they were unusually common in the Paris hospitals during the Commune in 1871, when the wards were filled with the intemperate and half-starved victims of that insurrection. And this fact leads him to regard the condition as epidemic. It appears to M. Verneuil to depend upon the condition of the wound, and the constitutional state of the patient. Thus, it did not occur in clean, healthy wounds, but nearly always in contused wounds, with adherent sloughs. The constitutional conditions with which it was associated in his cases were diabetes mellitus, phosphaturia, alcoholism, and morphinism. As a rule it was temporary, but was continuous in some very bad cases. He regards it as a sign of danger, but has seen no reason to hold that it is usually associated with pyæmia, or invariably fatal, as Delore taught. The question naturally suggests itself whether the specific cause of this suppuration be not a peculiar fungus or "germ." M. Verneuil has no direct evidence to give on this head, and the late M. Broca failed in some cultivation-experiments undertaken to throw light on this point.

EMIGRANT SHIPS.

COMPLAINTS have recently been made as to the treatment experienced by emigrants on board many of the vessels engaged in the transatlantic trade. Several of the leading English companies have written to clear themselves of the charges of neglect, overcrowding, and inadequate supply of provisions, which have been, we think, somewhat recklessly brought against them. It is well known that, so far as emigration from English ports is concerned, strict Government supervision is exercised, and we believe that on the whole the business is well conducted and the emigrants are fairly and even liberally treated. But this may not be the case with ships sailing from foreign ports. Thus we find that, whilst the English liners sailing from Liverpool do not charge less than £6 per steerage passenger, there are continental lines which advertise to supply a berth of the same class for less than that amount, although the passage to New York from a continental port must take at least two days longer than from Liverpool. It is probable that the cheaper fare tempts many to take their passage in the vessels of these foreign companies, whilst there is reason to fear that many pay their money to agents in London under the idea that the vessels they are about to sail in are under the supervision of our Government, whereas they are shipped across to some continental port to be embarked in the vessel of some foreign company. This supposition is borne out by a letter addressed to the *Bristol Mercury* of the 10th inst., by an emigrant whose experience, as described by himself, was as follows. In common with a number of other Englishmen, he was attracted by an advertisement offering a cheap passage across the Atlantic by a vessel starting from London, as was supposed, but afterwards found had Antwerp as the port of departure. The accommodation at Antwerp pending the ship's departure was filthy in the extreme. Properly filled, the steerage would accommodate about 250 persons, whereas nearly 500 where crowded into it. The living on board was wretched, and for the tea and coffee water was used which was foul beyond description. The sanitary arrangements may be judged by this one fact—the closets for the males and females respectively (nearly 500) were on either side of the steward's cabin where the food stood before being served out at each meal! We would defy even Mark Tapley to have been "jolly" under such circumstances. This is not the first time that complaints of a similar nature have reached us, and it appears to be quite time that Government, through our consuls, should make inquiries as to the condition of the emigrant ships sailing with British subjects on board from foreign ports. If it be found that by means of agents employed in London, and through advertisements in the London papers, English emigrants are induced to embark in vessels in which the salutary regulations enforced on English ships are neglected, Government should at once take steps to put a stop to the evil, at least so far as concerns the interests of British subjects. No booking of emigrants should be allowed at any office in England unless the agent be prepared to show that the vessel in which they were to be conveyed had fully complied with all the Government regulations.

THE OSSEOUS LESIONS IN LOCOMOTOR ATAXY.

AN account of a fresh investigation into the minute changes in the bones in ataxy has been published by M. R. Blanchard, in the *Gazette Médicale de Paris.* It had been previously ascertained that the essential change is absorption of the bony tissue around the Haversian canals, most marked in the neighbourhood of the medullary canal, and that the disappearance of the bony structure is preceded by a localised decalcification. The present investigation has been undertaken to compare this change with the clinical symptoms, and to ascertain whether it is the same in the cases which present fracture of the long bones or atrophy of the epiphyses, phenomena which are not commonly associated in the same patient. The examination has been made on the bones contained in the Salpétrière museum the history of which was well known. The result has shown that the lesions are exactly the same in the two sets of cases. The only differences found are those of degree, and do not explain the difference in the symptoms. M. Blanchard is inclined to explain the fact that patients with disease of the head of the bone do not suffer from fractures of the shaft by the impairment of movement which the former causes, which prevents the limbs being used with sufficient force to cause the spontaneous fractures. Whenever the heads of the bones are eroded, the shafts present the same change as in those which have broken. The converse, however, is not true; the change in the shaft may be met with, and yet the ends of the bone may present no erosion.

MANAGEMENT OF PRISONS.

AN influential deputation met the Home Secretary a few days ago, to lay before him resolutions passed at the Conference of the Prison Visiting Committees, held at the Westminster Palace Hotel on the 31st ult. The Home Secretary, after the resolutions had been brought forward, promised that they should at once receive the attention they deserved. Among some of the more important recommendations to which he promised especial attention would be paid we notice the following: better provision for the isolated treatment of prisoners suffering from fever; all post-mortem examinations of bodies of prisoners to be conducted by independent medical men; the punishment of female prisoners in dark cells to be abolished; the discontinuance altogether of the use of plank-beds in the case of women, and the modification of this kind of punishment in the case of men. These are matters to which THE LANCET has repeatedly drawn attention, and we hope the much-needed reforms in this direction will ere long be effected. We should also be pleased to learn that the effect the new prison dietaries had on the health of the prisoners generally had not been overlooked. We have frequently pointed out the severe character of the diet for short-termed prisoners, and that, taking the diets of all classes, the punishment falls very unequally; for while the agricultural criminal would only feel the reduction in quantity, the town convict would be affected by the alteration in quality as well as by the lessened quantity. Most of the mishaps that have occurred during the last three years, since the introduction of the new diets, have arisen among short-termed prisoners, or during the early period of the confinement of those sentenced for a longer term.

STORED ELECTRICITY.

THE public attention directed to the importance of the possibility of storing force and using it economically when needed cannot but bring about results of the greatest importance. The practical mind of M. Faure and the genius of Professor Thomson have attained results from the important discovery made some three or four years since by M. Planté of which the original inventor possibly scarcely dreamt. The Planté polarisation cell, of which M. Faure's battery is a modification, is composed of two sheets of lead wrapped spirally round each other, kept separate by the interposition of slips of vulcanite, and immersed in dilute acid. The cell is charged by being included in the circuit either of an ordinary electric battery or one of the modern electrical machines — Gramme's or Siemen's. As a result of this, the lead-plate in connexion with the positive pole of the battery or machine becomes oxidised on the surface. The cell is then disconnected, having, by the chemical electrolytic process induced in it, become itself a powerful battery capable of manifesting energy in proportion to the size of its plates and the amount of oxidation of one of them. The public is likely to be misled as to the originality of using a polarisation cell for medical purposes. This was done long ago, and indeed the polarisation cells made by Trouvé of Paris have been already found of great service, not only on the Continent, but in this country and in America. These (Trouvé's) elements have been used as a convenient source of light for medical and surgical purposes and for laryngeal and other kinds of mirrors. Endoscopes have also been made whose illumination is brought about by a platinum wire rendered incandescent by means of a Planté cell. The incandescent wire has also been employed as a cautery for minor surgical operations.

THE CONTAGIOUS DISEASES ACTS.

WE are glad to observe the satisfactory result of Sir W. Harcourt's inquiries into the charge, implied in a question by Mr. Hopwood, that the surgeons appointed under the Contagious Diseases Acts for the boroughs of Portsmouth, Windsor, and Southampton "had been made justices of the peace in order that they might carry out the Acts in a two-fold capacity — administering and executing the law." Sir W. Harcourt stated that he "found that the three gentlemen in question were justices of the peace; but they had assured him in the most explicit way that they did not act in any case connected with the Contagious Diseases Acts, and that they would think it highly improper to do so." In this view everyone must concur. The Acts are of great importance, and, as we have repeatedly pointed out, have effected much practical good; but it would be intolerable if those who are entrusted with the duty of putting them in force were to be permitted to sit in judgment upon any of the unfortunates who might be accused, rightly or wrongly, of contravening the police regulations. There can be no possible objection to the gentlemen referred to remaining on the commission of the peace so long as they adhere to their judicious determination to avoid adjudicating in any cases occurring under the Acts.

MAKING A RIOT.

IT is always with regret we feel compelled to draw attention to what may seem to be misconduct on the part of the police; but unless some more satisfactory explanation than has yet appeared is forthcoming of the "Riot in Southwark" on Sunday evening last, it will be impossible not to think that the force has been discredited by some of its members. It may be conceded that policemen have much to try their tempers. This, however, is no reason why they should first rush into an act of official folly and then lose their heads with excitement when they find the popular sympathy is against them. A young man, said to have lost his brother by drowning, became greatly excited, and, stripping off his clothes, was about to plunge into the water to recover the body. It was a silly and indecorous thing to do; though the time was evening, and but that a police-constable *happened* to spy the offender, nothing would have come of the affair. As it turned out, the policeman pounced on the young man, and he resisted. A struggle ensued, and assistance was procured. The roughs sided with the wrongdoer, and the police were badly treated. A magistrate has since sent the young man to prison for three months. It would be well if the Home Secretary ordered an inquiry into the matter. If the police were only half as zealous in protecting the public from the real and intentional or vicious offences committed against decency, even in "respectable" neighbourhoods, as they have shown themselves in this instance, and are wont to show themselves in pursuing little boys who try to pick up an honest penny by selling matches, there would be more order in our streets, and less frequent occasions for popular complaining.

EXPERIMENTS ON NERVE-STRETCHING.

SOME interesting experimental results of nerve-stretching have been obtained by M. Quinquaud. He lately showed to the Société de Biologie two guinea-pigs in which the sciatics had been stretched, and in which the operation had been followed by a spontaneous amputation of the two outer toes, innervated by the sciatic, while the inner toe, innervated by the crural nerve, was intact. The trophic changes resemble closely those which follow division of the nerve. On another guinea-pig he observed a very curious phenomenon. He stretched the sciatic on the right side, just enough to cause anæsthesia; then he stretched the other sciatic much more violently, so as to cause a strong excitation. The effect of the latter was to cause the sensibility in the right leg to return, and to be replaced, a few hours later, by hyperæsthesia. The experiment succeeds best in young guinea-pigs. This phenomenon, which he terms "mechanical transfer on irritation," shows that across the spinal cord there must be produced a modification in the action of the nerve-cells analogous to that which has been studied by Dr. Brown-Séquard. If the anæsthesia on the right side is of old standing it is not removed by stretching the left nerve. M. Marcus has found that if a stretched nerve is treated immediately with osmic acid, and transverse sections are examined, the axis-cylinder is seen to be no longer immediately enclosed by the myelin-sheath, but a zone, colouring yellow, intervenes between the two. At subsequent periods the signs of degeneration in the nerve are found. The third day after the operation numerous fibres appear intact, but in others the myelin has become segmented, and the axis-cylinder has disappeared. In some the latter persists, and the outer sheath is closely applied to it, the myelin having gone. The nuclei of the neurilemma are increased in size and number. These changes are much more marked in guinea-pigs than in cats, even when care is taken to render the operation as nearly as possible similar in the two animals. In the cat, however, the spot stretched becomes distinctly swollen, and the lesions above described have been found in the central, and not in the peripheral, part of the nerve. In some cases the lesions are very slight. In one cat, in which the sciatic was stretched so as to cause complete anæsthesia, no histological changes could be found either in the nerve-trunk or the posterior spinal roots.

THE SANITARY CONDITION OF THE HOTELS OF ROME.

We are glad to learn that a proposition to discuss, by the Italian Medical Association, with reference to the *Italian Times*' Sanitary Commission, the "measures to be taken in view of the arbitrary interference of certain foreign medical practitioners with the hygienic condition of the Roman hotels," has been suffered to lapse. But an Italian physician has addressed an article to the *Popolo Romano* questioning the right of foreign physicians to interfere with Roman sanitary questions. It would appear, however, from this article, that other than structural arrangements in the hotels should enter into the consideration of the commission, and be borne in mind by visitors. This Italian physician relates the following story:—"A short time since a Protestant clergyman attended a lady, one of his co-religionists, who died of typhoid fever in one of the principal hotels of Rome. The next day the same clergyman called on a bishop, who had just come to Rome, and had gone to lodge in the same hotel. To his great surprise he found him occupying the very room in which the lady had died of typhoid fever the day before." "The Italian physician," the *Italian Times* remarks, "sees nothing disquieting or improper in this." We apprehend that English visitors to Rome, at least, will see much to disquiet them, and it is well to have the assurance of our contemporary that the Roman hotel-keepers are welcoming the Sanitary Commission which it has established.

RHABDITIS GENITALIS.

The above is the name given by Schreiber to a microscopic round worm of the genus Rhabditis, that he has found in the urine of a female patient. The woman was thirty-five years of age, and suffering from advanced pulmonary disease. The urine contained pus, was feebly acid, and quickly became alkaline. On examination of the sediment, large quantities of peculiar worms were found in it. The smaller ones were asexual, mostly dead, and only one-fourth or one-fifth of a millimetre in length; the larger were sexually mature and alive. Of these the males were about one millimetre long, with expanded wing-like tails; the females were rather longer, had conical heads, and narrow, pointed caudal extremities, and contained eggs in various stages of cleavage. The external genital organs and the vagina were thoroughly cleansed, with the result of completely freeing the urine from the parasite. It was thus made abundantly clear that the worm was not a urinary, but a genital parasite, and only accidentally mixed with the renal excretion. This adds another to the known list of animal parasites.

HEALTH OF THE FRENCH TROOPS IN TUNIS.

Various reports have been current for some time concerning the unsatisfactory sanitary condition of the French army in Tunis; but from an official statement, emanating from the Minister of War, it would appear that these are incorrect. From the 25th to the 31st of May the proportion of sick, including those suffering from fever, was two per cent. of the whole strength, whereas the mean proportion of sick for the whole of France was four per cent. It is also stated that the medical department is prepared to meet any emergency, having sixteen hundred vacant beds at its disposal in the hospitals of the province of Constantine, and in the ambulances of Tunis. The evening papers of Tuesday (*Le Temps, La Liberté, La France, L'Estafette,* and probably also others) publish a note communicated by the Havas Agency, contradicting a statement which appeared in *The Times*, concerning the prevalence of typhoid fever amongst the French troops. It runs as follows:—"*The Times* has published, on the sanitary condition of the troops in Tunis, and on the supposed ravages made by typhoid fever, information which is entirely untrue [*inexact*]. We are in a position to rectify it. In reality, the number of sick or wounded of the expeditionary corps at present in the hospitals of the Regency and of the province of Constantine (Boue, La Calle, Guelma, Soukahrrhas), where the sick of the different columns have been evacuated, amounts to 486, which for a total of 26,300 men gives a proportion of two per cent."

TRICHINA-LIKE PARASITES.

To microscopists who are endeavouring to ascertain the various habitats of trichinæ, a useful word of warning has been given by M. Mégnin in a paper read before the Société de Biologie, in which he points out that many minute encysted worms are met with which are not trichinæ, although so closely resembling them as to have deceived many observers. The supposed discovery of trichinæ in the rootlets of beetroot, proved to be a mistake by Virchow and Kuhn, is a striking instance of this sort. Langenbeck described trichinæ in the intestines of earth worms, but Kuhn showed that the parasite is quite distinct from the trichina spiralis. Merlan and Tigri thought they had found trichinæ in the lungs of sheep, but Delpech showed that these were merely the embryos of strongylus filaria. Cobbold has stated that the trichina is common in the hedgehog. Mégnin is convinced that this is an error, and that the worms described are merely the encysted larvæ of the spiroptera clausa. He showed preparations of an encysted nematoid worm, which might easily be mistaken for the trichina, but pointed out that the former differs in having a papilla at its mouth, and the anus is not terminal. Siebold described as a trichina a worm found in cysts in the peritoneum of the grey lizard and other creatures, but Mégnin asserts that this also is the larva of a spiroptera (S. abbreviata), the adult individuals of which are abundant in the intestines of the same animal. An encysted spiroptera still more strikingly resembling the trichina has been found in the muscles of the frog. Very similar, but larger, encysted worms of the same genus have also been discovered in the subcutaneous tissues of a bird, the manchetes pugnax.

THE NEW EXHILARANT.

Our readers probably observed with some surprise the announcement in *The Times* of the remarkable exhilarating effect stated by M. Luton of Rheims to be produced by a not very unusual combination of drugs, ergot of rye and phosphate of soda. In case they may desire to make some observations on the point, we give the doses alleged to produce the extraordinary effect. Tincture of ergot of rye five grammes (about eighty-five minims); phosphate of soda twenty-two grains: dissolved in a small quantity of water, and taken in a single dose, fasting. The effect on the first patient was manifested in three-quarters of an hour. She laughed continuously for half an hour, and each dose was followed by similar effects. Another patient in the same ward begged to take so delightful a drug, and manifested similar effects, and so also did an old woman of seventy-one. In a chlorotic girl it caused at first some nausea, then flushing of the face; an agreeable warmth spread over the body, and shouts of laughter burst forth and continued during the greater part of the day. In men, however, no such effects were produced—merely slight giddiness and headache.

MEDICAL WORTHIES OF BRADFORD.

THE *Bradford Observer* of May 17th contains a paper by Dr. J. H. Bell, entitled "Fragments of Local Medical History," which we have read with much interest. The sketches of medical men associated by birth, connexion, or practice with Bradford are very well drawn, and supply many social and professional data of real historic value. The list begins with Dr. Bartlett, F.R.S., born in Bradford in 1718, and includes the great and good Dr. John Fothergill, who was a friend of Bartlett. A medical man is not badly employed in reviving in a community the memory of men of his own profession; and that Dr. Bell should have found time to do this at a moment when he is so honourably distinguished in connexion with a piece of good medical and pathological research, is a new proof of an old truth—that the study of the old and the new often go well together, and that one kind of work serves as recreation in respect to another.

THE PIROGOW JUBILEE.

M. PIROGOW'S jubilee, celebrated at Moscow on the 6th inst., was made the occasion of an extraordinary demonstration in honour of the distinguished Russian surgeon. The State, scholastic, literary, and scientific circles, and the people generally, all crowded to do honour to the jubilee, and the detailed accounts of what transpired fill much space in the Russian journals. Addresses were read in honour of the occasion from all parts of the empire, and from numerous foreign universities.

THE Throat and Ear Hospital, Newcastle-on-Tyne, was last week visited by Dr. Yong Ton Wong, the native physician on board the *Hae Shin*, accompanied by his assistant and interpreter. The doctor, who is about forty years of age, studied at Canton, of which city he is a native. The visitors were received by the honorary secretary, and Mr. Ellis, the senior-surgeon, and appeared to be much interested in the examination of the out-patients. They showed good acquaintance with the use of electricity and galvanism in the treatment of disease, and stated incidentally that Chinese medicine aimed at prevention rather than cure, and that they preferred to save a limb rather than to sacrifice it by an operation.

DR. GEE, physician to St. Bartholomew's Hospital, has recently had under care in the wards a girl, fourteen years of age, suffering from chorea. About ten days after chloral hydrate was prescribed for her in frequently-repeated doses, a characteristic eruption, now known to be due to the administration of this drug, appeared upon the upper part of the chest, elbows, and buttocks. Consisting essentially of a lichenous type, the papules were generally large, of a dusky hue, and surrounded by much cutaneous redness. An example of this interesting skin lesion—also under Dr. Gee's care—was noticed in THE LANCET of January 1st.

AN accident, which at one time caused serious alarm, occurred in the Anatomical Schools of Cambridge University last week. By the ignition of some spirit the preparation room caught fire, to which apartment, however, it was, by the exertions of the servants of the museum and of the fire brigade, fortunately confined. No specimen of value appears to have been destroyed, though the room was much damaged.

ON Monday last, the Bishop of Gloucester and Bristol distributed the prizes to the successful students of the Bristol Medical School. The report read by Dr. Markham Skerritt referred to the facts that the building in which the work of the school is carried on is a temporary one, and that, owing to the increase in the number of students, additional accommodation is urgently required. The Bishop, in the course of his address, deprecated specialism, and spoke forcibly on the need, in medical practitioners, of a broad and general knowledge of the human frame and its diseases.

THE suit instituted by a Mrs. Morgan in the Supreme Court of the United States against Dr. Lewis H. Sayre, in which the plaintiff demanded 25,000 dollars damages for alleged injuries to her constitution from the improper administration of nux vomica, has, as was to be expected, resulted in a verdict for the defendant.

MR. JOHN TWEEDY, F.R.C.S., has been elected Professor of Ophthalmic Medicine and Surgery at University College, on the retirement of Professor Wharton Jones, F.R.S. Mr. Tweedy has also been appointed Assistant Ophthalmic Surgeon to University College Hospital.

THE Boylston Prize of Harvard College, U.S., for 1881, has been awarded to Mr. Herbert Page, of St. Mary's Hospital, for the best essay on "Injuries of the Back, without apparent Mechanical Lesion, in their Surgical and Medicolegal Aspects."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Holsworthy, Rural (Devonshire).—Population, 1871, 9427; area 81,810 acres. Mr. Linnington Ash reports for 1880 a birth-rate of 29·17 per 1000 living, and a death-rate of 19·62. Of this death-rate he remarks that although somewhat lower than the average of all England, it is a high rate for an extensive, high, moorland, and sparsely populated district—higher, indeed, than ought to exist. An exceptional prevalence of certain zymotic diseases appears to have contributed largely to the comparatively high mortality, especially measles and scarlet fever. The sanitary organisation of the district is still so imperfect as to place successful attempts to limit the prevalence of infectious diseases out of the question. There are no public means of isolating patients, and isolation in the cottages of the poor is practically impossible; disinfection, too, as practised in the district, is described by Mr. Ash as "perfectly useless and illusory. It is done in a desultory, unmethodical, and unscientific manner, as might be expected in the absence of proper public means for the purpose being provided by the authority." In respect to the closure of schools, Mr. Ash observes, in regard to measles: "Schools were temporarily closed in nearly every parish, but always too late to be of use, for the most infectious stage of measles is the commencement, even as soon as, or before, the characteristic rash appears. More than a dozen children attending one of the schools in Holsworthy were struck down with the disorder during one afternoon." Scarlet fever, it appears, spread from village to village, "chiefly through the means of elementary schools for combined districts." The present report is the sixth annual one which Mr. Ash has been called upon to make for this district. He comments upon the fact that no systematic records are yet kept of the work done by the inspector of nuisances, and that no systematic survey for sanitary purposes has been made. Much has been done in respect to sanitary work since the district was formed, and progress is being made; but it is obvious that much remains to be done, and that from the want of the work which has been done, and is now being done, not being carried out in the orderly way which Mr. Ash advises the full utility it should have for the district is not obtained.

Cambridge (*Urban*).—Dr. Bushell Anningson reports for this university town and district for 1880 a death-rate of 16·4 per 1000 living, but he thinks it desirable to repeat a caution that a low general death-rate should not be taken by itself as an expression of healthful conditions of a town, and he further says of Cambridge that, "like a weakly creature, she 'catches any complaint that is going.'" The complaint "going" in 1880 was diarrhœa, and Cambridge did not escape; and, in consequence, came in for the polite attentions of the Local Government Board inviting contribution to the investigation as to diarrhœa, which is now being carried out by Dr. Ballard. The cream of the contribution which Cambridge will make to Dr. Ballard we may assume is given in this report. Dr. Anningson describes the meteorological conditions under which the considerable prevalence of diarrhœa among infants and young children occurred in the town, but shows that such influence as they exerted in the production of the disease was manifested not generally over the town and district, but was confined to certain limited localities. He then proceeds to examine into the peculiar conditions which might determine these localisations, and particularly of the district upon which the incidence of the diarrhœa most markedly fell. He observes:—"That focus comprises not only the courts and alleys and yards where the air stagnates, undisturbed except by a breeze from the sewer, but even streets that might be considered fairly ventilated. The conclusion to which I am rather unwillingly led (I say unwillingly, because if I am right the remedy is difficult of application), is that the infected area lies along the line of sewers of low rate of inclination in poor neighbourhoods, where less heed is paid to traps. So slight, indeed, is the inclination, that the sewage is practically stagnant, and ferments, producing gases which press with great force, as I know by direct experiment, upon the traps in some of the scullery sinks. The evil, doubtless, would be palliated by ventilation of the sewer all along its line (a matter to which I called attention in my first report—viz., that for 1875). There would even then be foul gas in the streets, but in a less concentrated state."

Fulham.—Mr. Collier, in his report for the first quarter of the present year, gives the rate of mortality as equal to 20·0 per 1000 of the population of the district, as compared with 23·3 for the whole of the metropolis. He has the following observations upon small-pox in the district:—"In my last quarterly report, attention was called to the fact, that a large number of cases of small-pox were being removed from other districts of the metropolis to the Metropolitan Asylum Hospital at Fulham, for the purpose of isolation. An opinion was expressed that an outbreak of small-pox would occur in the parish of Fulham, as a result of the course that was then being adopted. At the time of the presenting of that report, there had been no case of small-pox reported in the parish of Fulham for a period of over three months. During last quarter, 97 cases were reported in this district, against 3 cases in the previous quarter, and against 33 in the corresponding quarter of the previous year. Of the 97 cases reported last quarter, 75 occurred in the parish of Fulham and 22 in the parish of Hammersmith, against none in the parish of Fulham, and 3 in the parish of Hammersmith reported the previous quarter; 58 of the patients were males and 39 females. The ages varied from two weeks to sixty-three years. The average ages was 21·7 years. Eighty-two of the patients had been once vaccinated; 8 had not been vaccinated. In the remaining 7 cases, no information as to vaccination was obtained. These 97 cases occurred in seventy-two houses in fifty-nine streets. In forty-seven streets the outbreak was confined to one house in each street; 40 cases occurred singly in different houses in different streets; in twelve streets there was more than one house attacked in each street. In one street, there were three houses attacked in the same street, and in eleven streets there were two houses attacked in each street. In sixty-three houses, there was only 1 case in each house. In nine houses, there was more than 1 case in each house. Thus, in one house there were 8 cases in the same house; in one house there were 5 cases in the same house; in three houses there were 4 cases in each house; in one house there were 3 cases in each house, and in three houses there were 2 cases in each house. Of the 97 cases, 5 deaths have as yet been registered, which equals a mortality of 5·1 per cent. 91·8 per cent. of the cases were removed to a hospital and properly isolated; 89 cases were removed to the Metropolitan Asylum Hospital at Fulham—88 by your board and one by St. Thomas's Hospital authorities. The patient applied there for medical advice, not knowing the nature of his complaint. One case was not reported till after the death of the patient; 5 cases were not reported till after the recovery of the patients, and in 2 cases the removal was objected to. The accommodation in these latter two cases was by no means satisfactory for the effectual isolation of the patients, but was not sufficiently bad within the meaning of the thirty-eighth section of the Sanitary Act, 1866, to justify an application to the magistrate to enforce removal. Only 12 of the cases were within a half-mile radius of the Fulham Small-pox Hospital, while 85 were without about a half-mile radius. These facts are opposed to the theory that the disease is caught by the germs being carried through the air from the hospital. Under such circumstances, the houses that are in the nearest proximity to the hospital would be most affected by the disease. The very large number of cases that have occurred in the *three parishes* that are in the nearest proximity to the hospital, as compared with those parishes that are more distant, is, on the other hand, the strongest evidence *that the presence of the hospital in the locality is the cause of the disease being more prevalent in that locality.*" In his observations upon the diffusion of "germs," Mr. Collier gives no clue to the respective populations living within and without the half-mile area from the hospital, and among whom the cases to which he refers occurred.

ALLEGED DEATH FROM REVACCINATION.

With regard to the reported death of a lady at Sittingbourne from revaccination, to which we referred a fortnight ago, we learn from the medical gentleman in attendance (Dr. C. H. Fisher), that there was not the least connexion between the revaccination and the cause of death. The revaccination failed, and the erysipelatous affection from which she afterwards died had no connexion with the spot where the vaccine lymph had been inserted.

MISTAKING SMALL-POX FOR CHICKEN-POX.

Dr. Orme Dudfield, in his report for May, directs attention to the extension of small-pox from the lower classes in the social scale to the higher; and he gives a curious instance of a succession of cases of presumed chicken-pox proving to be modified small-pox, and the error leading to a regrettable diffusion of the malady.

It would appear from the last meeting of the Metropolitan Asylums Board that the second ship asked for from the Admiralty, the *Endymion* frigate, is to be used for the administrative staff attached to the *Atlas*, and that it is contemplated to fit up the latter ship for 250 patients. The Admiralty have also lent to the Board a steam pinnace to facilitate its arrangements. It would seem probable that the *Atlas* and *Endymion* will be moored off Greenhithe, but the riverside authorities, the Port of London Sanitary Authority, and the Thames Conservators are all throwing difficulties in the way of the Asylums Board establishing a floating small-pox hospital in the river, and it is to be surmised that the Board have been at no pains to remove these difficulties before they started their scheme. One of the members during the meeting, with reference to certain communications made to the Asylums Board by the Local Government Board, and the little help they received from the latter body, aptly said that the Board desired the managers "to pull the chestnuts out of the fire."

The Manchester Corporation, in view of the annual deficit in the receipts as contrasted with the expenditure of the Monsall Fever Hospital, belonging to the Royal Infirmary, has agreed to pay an increased sum for the maintenance and treatment of each case sent there under their authority. Doubtless other sanitary authorities making use of the hospital will follow a similar course.

If the medical officer is permitted to keep a dog in a workhouse, why not the matron, or, indeed, any other officer? This question has been occupying the serious attention of the Shoreditch guardians, and has been decided by conceding the same privilege to the matron as to dog-keeping as the medical officer.

Dr. Bristowe, the medical officer of health for Camberwell, has been delivering a series of lectures on sanitary matters in the Vestry Hall of the parish. The lectures were largely attended and highly appreciated.

The medical officer of health for Peterborough city, Dr. W. Sinclair Thomson, has resigned his post, which he had held since 1873. The thanks of the Town Council were voted to Dr. Thomson for the efficient manner in which he had performed the duties of his office.

The sanitary inspectors of Holborn and Clerkenwell, it is reported, have been giving attention to the probability of small-pox being spread by the sale of second-hand clothes, and are endeavouring to avert danger from this source.

The Cambridge Urban Sanitary Authority have determined to erect an infectious disease hospital, and to take measures for diverting the sewage of the town from the Cam.

The vaccination officer for Bethnal Green recently reported that a three weeks' house-to-house visitation of his district had led to the discovery of about 600 unvaccinated children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a marked decline, and was exceptionally low last week. In twenty of the largest English towns, estimated by the Registrar-General to contain in the middle of this year a population somewhat exceeding seven and a half millions of persons, 4718 births and 2737 deaths were registered last week. The births were 458, and the deaths so many as 520, below the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had been equal to 20·0 and 20·3 per 1000 in the two preceding weeks, declined last week to 18·8; this is the lowest rate that has prevailed in these towns in any week since the end of September last. The lowest rates in the twenty towns last week were 14·0 in Brighton, 14·6 in Portsmouth, 15·1 in Wolverhampton, 15·3 in Plymouth, and 15·4 in Newcastle-upon-Tyne. The rates in the other towns ranged upwards to 21·4 in Salford, 21·7 in Manchester, 22·7 in Liverpool, and 23·0 in Sheffield. During the first ten weeks of the current quarter the death-rates in the twenty towns averaged 20·9 per 1000, against 23·0, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 452 and 446 in the two preceding weeks, declined to 401 last week; these included 106 from measles, 91 from whooping-cough, 63 from small-pox, 55 from scarlet fever, 45 from diarrhœa, 27 from fever (principally enteric), and 14 from diphtheria. The annual death-rate from these principal zymotic diseases averaged 2·7 per 1000 in the twenty towns, and ranged from 0·0 and 0·5 in Newcastle-upon-Tyne and Brighton, to 4·1 and 5·9 Liverpool and Leicester. Measles showed the largest proportional fatality in Bristol, Sheffield, and Liverpool; scarlet fever in Norwich, Oldham, and Birmingham; and whooping-cough in Leicester, Portsmouth, and Birmingham. Of the 14 deaths from diphtheria in the twenty towns, no less than 11 occurred in London. The death-rate from fever, principally enteric, was exceptionally low in the twenty towns last week; it was highest in Portsmouth and Hull. The fatal cases of diarrhœa, principally infantile, showed an increase last week, but were below the average for the season. Small-pox caused 67 more deaths in London and its outer ring of suburban districts, 2 in Liverpool, and 1 each in Brighton and Hull; no fatal case of this disease, however, was registered in any of the sixteen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased from 942 to 1644 during the five preceding weeks, was 1633 on Saturday last, including 621 inmates of the Convalescent Camp Hospital at Darenth. The new cases admitted to these hospitals, which had been 402 and 359 in the two previous weeks, declined to 293 last week. The Highgate Small-pox Hospital contained 83 patients on Saturday last, against 84 and 86 at the end of each of the two previous weeks respectively; 19 new cases were admitted to this hospital during the week. These figures afford evidence that the decline of small-pox fatality, which is usual at this time of the year, has now set in.

The deaths referred to diseases of the respiratory organs in London, which had been 241 and 249 in the two preceding weeks, fell to 216 last week, and were 25 below the corrected average weekly number; they included 120 from bronchitis and 70 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, did not exceed 2·9 per 1000 in London last week; while the rate from the same diseases was 4·8 in Liverpool and 4·2 in Salford.

The causes of 69, or 2·5 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths in London did not exceed 1·5 per cent., whereas it averaged 3·5 in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth, Norwich, or Birmingham; whereas the proportions of such deaths were largest in Sunderland, Leeds, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half of persons, the annual death-rate last week declined to 18·7 per 1000, from 20·6 in the previous week; this rate was 0·1 below the average rate last week in the aggregate of the twenty large English towns. The rates in these eight Scotch towns ranged last week from 15·7 and 17·9 in Dundee and Glasgow, to 21·2 and 21·7 in Paisley and Leith. The rates of mortality in the Scotch weekly return are not yet calculated upon estimates of population based upon recently enumerated numbers; it is said to be probable that the rates in some of the towns are over-stated through an under-estimate of their present population. The deaths referred to the principal zymotic diseases in the eight towns were 65 last week, against 72 and 62 in the two preceding weeks; they included 19 from diarrhœa, 17 from whooping-cough, 11 from "fever," 6 from measles, 6 from scarlet fever, 5 from diphtheria, and one from small-pox. The annual death-rate from these zymotic diseases averaged 2·6 per 1000 in the eight towns, and was 0·1 below the average rate from the same diseases in the twenty large English towns. This zymotic death-rate ranged in the eight Scotch towns from 0·0 and 1·9 in Perth and Aberdeen, to 3·2 and 5·2 in Greenock and Leith. The 19 deaths referred to diarrhœa showed an increase of 5 upon those returned in the previous week, and included 8 in Glasgow, 4 in Greenock, and 2 each in Dundee, Aberdeen, and Leith. The fatality of this disorder was more than twice as great as that which occurred last week in the large English towns; 17 fatal cases of whooping-cough showed an increase of 3 upon the number in the previous week; they included 11 in Glasgow and 4 in Edinburgh. The 11 deaths referred to "fever" (including typhus, enteric, and simple) showed a further slight increase upon recent weekly numbers; 5 occurred in Glasgow and 3 in Edinburgh. The annual death-rate from this cause in the eight towns was equal to 0·44 per 1000, and was more than twice as high as the average fever rate in the twenty English towns. The 6 deaths from scarlet fever showed a decline of 7 from those in the previous week, and included 4 in Edinburgh. Four of the 6 deaths from measles were returned in Glasgow. The fatal case of small-pox was of an unvaccinated infant, aged four months, in Glasgow. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 89 and 106 in the two preceding weeks, declined again to 95 last week, and were equal to an annual rate of 3·8 per 1000; the rate from the same diseases in London did not exceed 2·6.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

HEALTH OF CALCUTTA.

Dr. K. McLeod's report for the first quarter of the present year on the health of Calcutta shows an unusually low mean temperature of the period, a quarterly total of deaths exceeding the decennial mean by 362, and, with the exception of bowel complaints, a decrease in the mortality from specific diseases below the mean of the preceding ten years. The mortality from cholera was below the mean, although higher than in either of the two preceding years. "An outbreak of considerable severity occurred in a bustee to the north of Sakea's-street, which subsided when the use of the water of a tank in the middle of the village was prevented by putting a police guard over it. A similar result happened in Parsee bazaar, a bustee near Machua Bazaar-street, where the people of their own motion discontinued the use of the water of a large tank situated in that village." The deaths from diarrhœa and dysentery were slightly in excess of the decennial mean; those from small-pox below; but the number of deaths from "other causes" (convulsions, tetanus, phthisis, liver and spleen diseases, &c.) was unprecedentedly large. A very general prevalence of measles interfered with the progress of vaccination, but it is hoped that next season the new law and arrangements will be in efficient working order.

THE ADULTERATION ACT IN GLASGOW.

The difficulty of dealing with adulteration, especially as regards such an article as milk, has again been shown in a case recently decided in the High Court of Justiciary. Mr. James Morton, once of City Bank notoriety, now a milk-dealer, near Paisley, was convicted a few months ago in the Sheriff's Court of having sold cream which consisted to the extent of 34 per cent. of skim-milk, and a fine was inflicted. Mr. Morton appealed to the higher court, however, and not in vain, his defence being that the cream sold was intentionally a cream of inferior quality, such as he knew his customers wanted and could pay for, and that he was quite willing to supply a better quality of cream at double or treble the price; it was all a question of price. The judges supported him in his contention, upset the standard of cream adopted in the lower court, and, apparently holding that the true end of the Sale of Food Act would be served if it prevented adulteration in the proper sense of the word—the addition of any foreign ingredients,—quashed the sheriff's decision. Inferiority in the quality of food sold, therefore, does not expose the seller to the penalties set forth in the Act.

TYPHUS IN ST. PETERSBURG.

It would appear from the *Medical Gazette* of St. Petersburg that that city is experiencing almost as great a difficulty as to hospital accommodation for cases of typhus as London is now experiencing in regard to cases of small-pox. Typhus has so largely increased in the northern city during the past three months that the hospitals prepared for its reception no longer suffice for the hosts of applications, and considerable numbers of patients have to be treated in their own homes. The demands of the epidemic in respect to bed accommodation in the special hospitals have been under estimated, and it is intimated that the failure of the municipality to provide a permanent hospital for typhus, which prevails more or less in St. Petersburg every year, must be held accountable in part for the great development which the malady has recently undergone. The mortality from the disease is also stated to be exceptionally great.

On Tuesday last Mr. Burt, M.P. for Morpeth, was summoned for non-compliance with a vaccination order made in April last, respecting one of his children. Mrs. Burt, who appeared for her husband, admitted the charge. The Bench inflicted a fine of 20*s.*, and suggested to Mrs. Burt that she should read the evidence recently published, showing the great liability of unvaccinated persons to small-pox.

The purification of the river Yarra-Yarra, Melbourne, is a question that appears to be coming to the front in the colony. The water-supply of the capital of Victoria is beginning to excite great dissatisfaction.

We hear that Mr. John Vance, L.R.C.P., and his wife, are suffering from the evil effects of diphtheria, contracted by him in the discharge of his professional duties in the West Ham district.

A camp hospital for the reception of cases of infectious disease has been opened at Finchley by the vestry of St. Mary's, Islington.

Diphtheria is reported to be prevailing extensively at Stockdale, Ontario.

THE SERVICES.

EXCHANGES OF MEDICAL OFFICERS SERVING IN INDIA.

The following appears in Army Circulars, June 1st, 1881.—Clause 129: medical officers serving in India who may wish to exchange to England, under the provisions of General Order 43 of 1881, will be required to forfeit their pay for the interval between their departure and their successors' arrival.

Brigade Surgeon F. R. Wilson, M.B., half-pay, Army Medical Department, has been appointed to the medical charge of the Brigade Depôt, Perth.

Surgeon-Major William Niven, M.D., of the Bombay Army, and Surgeon Henry Ogilvie Stuart, of the Bengal Army, have retired from the service.

Surgeon-General William Munro, C.B., has arrived in England from Gibraltar, on leave of absence.

Brigade Surgeon Wm. Cattell has embarked for Malta for duty, vice Brigade Surgeon Hiffernan, deceased.

Surgeon-Major A. F. Bradshaw, late Surgeon to the Commander-in-Chief in India, has been ordered to Devonport for duty in the South Western District.

ADMIRALTY.—Fleet Surgeons Charles Strickland, to the *Minotaur*, vice Francis T. Toms; Samuel Campbell, to the *Northumberland*, vice Gordon Jackson; Gerald Molloy, to the Plymouth Division of the Royal Marines, vice Henry Loney. Staff-Surgeon Alexander M'Donald, to the *Achilles*, vice Gerald Molloy. Surgeon and Agent Daniel Maguire, to Portavad, vice Robert M'Munn.

ROYAL COLLEGE OF PHYSICIANS.

THE adjourned meeting of the Comitia of the Royal College of Physicians to continue the consideration of the communications from the Secretary of the Medical Acts Commission, was held on Wednesday last, the President, Sir W. Jenner, Bart., in the chair.

Notice had been given to move the following resolutions:—

1. "That the College would regard with strong disapproval any proposal to establish a new licensing board or body which would practically supersede the power to grant licences conferred on the College by charter of King Henry VIII., which licence is the only one granted in this kingdom that confers on its holder a complete qualification to practise medicine, surgery, and midwifery, in all their branches." 2. "That the College could not consent to any interference with the mode in which it confers the distinction of Fellowship on its members." 3. "That the above resolutions be forwarded to the Secretary of the Medical Acts Commission, with an expression of the readiness of the College to depute one or more of its Fellows to give information on the above, or on any other subject named in the circular letter of May 23rd, which the Medical Acts Commission may consider that the College can supply."

The first of these resolutions was moved by Dr. Sieveking, seconded by Dr. Russell Reynolds, but withdrawn in favour of the following, which was proposed by Dr. Wilson Fox, seconded by Dr. Hermann Weber, and adopted after much discussion, in which Drs. Priestley, Barclay, Buchanan, and Greenhow took part. As to the wording of the resolution, it ran as follows:—"That this College feels it right to submit to the Medical Acts Commission that the appointment of a new licensing board, independent of the Royal Colleges of Physicians and Surgeons, is not only unnecessary, but would be likely to be prejudicial to the interests of the public, and to injure the profession, by lowering the number of licentiates of this College, and creating a body of licensed practitioners over whom neither the College of Physicians nor the College of Surgeons could exert any control. The College believes that the qualifications implied in the possession of its licence are adequate evidences of professional knowledge, and that its licence is esteemed alike by those holding it, by the whole of the medical profession, and by the public."

In the place of the above second resolution (the adoption of which was urged by Dr. Stewart) the following was moved by Dr. Sieveking and carried:—"That the College is of opinion that any material change in the manner in which the distinction of the Fellowship is conferred on its members would be highly prejudicial to the honour and dignity of the College, and would lower the estimation in which its Fellowship is now held by the profession and by the public."

It was also resolved (in lieu of the above No. 3 Resolution):—"That the Royal Commission be informed that the College has considered the letter sent to the College by the Secretary of the Medical Acts Commission, and has authorised its Registrar, Dr. Pitman, to attend and give information to the Commission on matters connected with the position, powers, and objects of the Royal College of Physicians;" and, on the motion of Dr. Maudsley, "That the Resolutions adopted at this meeting be entrusted to Dr. Pitman, as instructions for his guidance in the evidence which he may give before the Royal Commission."

The President then nominated Dr. Poore to deliver the Bradshaw Lecture in August next, and the Comitia adjourned.

THE INTERNATIONAL MEDICAL CONGRESS.

SINCE we published the first list of officers nominated for election at the forthcoming meeting of the Congress only few changes have occurred. *Ex officio* Sir William Jenner, as President of the College of Physicians, presides over the Council; Dr. Burdon Sanderson is to take the place of Vice-president of the Pathological Section, rendered vacant by the death of Dr. Sanders; one of the Vice-presidents of the Congress, Dr. Hudson, has died, and a third secretary in the Surgical Section, Mr. Rickman J. Godlee, has been appointed. Sir William Jenner is to preside at a meeting of the General Council on June 23rd, and, afterwards, Sir James Paget, President elect of the Congress, will give a reception to the members of the Council. Application has been made to the various European railway companies to give special facilities to members of the Congress, and Lord Granville requested the British ambassadors to the foreign Courts to interest themselves in obtaining concessions. All the French railways, and the South Eastern, and the London, Chatham, and Dover Railways, will give return tickets at single fares. As already announced, the offices of the Reception Committee of the Honorary Secretary-General and of the Editors of the Daily Programme are at the Royal College of Physicians, where a reading and writing room will be provided for members of the Congress. We would draw special attention to the facts that the Reception Committee will be glad to receive the names of any persons desirous of entertaining members for the week; and a book has been provided for registering the private engagements of foreign visitors, which is already being rapidly filled up. The following daily programme has been issued as a provisional scheme :—

Tuesday, August 2nd, 10 a.m. to 6 p.m.: Registration of members and issue of tickets at the office of the Reception Committee in the Royal College of Physicians, Pall-mall East. *3 to 6 p.m.:* Reception of the members of the Congress by the Executive and Reception Committees at the Royal College of Physicians.

Wednesday, August 3rd, 8 a.m. to 6 p.m.: Registration of members and issue of tickets at the Royal College of Physicians. *11 a.m.:* First general meeting, St. James's Great Hall; address of welcome by the chairman of the Executive Committee; Secretary-General's Report; election of officers and constitution of the Congress; election of Honorary Presidents of the Congress; election of Honorary Presidents of the Sections; Inaugural address by the President of the Congress. *3 p.m.:* Meeting of the Sections; constitution of the Sections; and other business. *9 p.m.:* Conversazione at South Kensington Museum (entrance Exhibition-road), given by the English members of the Congress to the foreign members.

Thursday, August 4th, 10 a.m. to 1 p.m.: Sectional meetings. *1.30 to 3.30 p.m.:* Visits to hospitals—Guy's Hospital, London Hospital, St. George's Hospital, St. Mary's Hospital, St. Thomas's Hospital, Westminster Hospital. The medical officers and lecturers will be prepared to receive such members of the Congress as may desire to visit these hospitals, and to inspect their schools and museums. *2 to 3.30 p.m.:* Additional meeting time for the sections. *4 to 5.30. p.m.:* Second general meeting, theatre of the University of London; address by Prof. Maurice Raynaud, Paris, "Le Scepticisme en Médecine, au temps passé et au temps présent." *6.30 p.m.:* Banquet given to a certain number of the members of the Congress by the Lord Mayor of London, at the Mansion House.

Friday, August 5th, 10 a.m. to 1 p.m: Sectional meetings. *1.30 to 3.30 p.m.:* Visits to hospitals—Bethlem Hospital, Charing-cross Hospital, King's College Hospital, Middlesex Hospital, St. Bartholomew's Hospital, University College Hospital. The medical officers and lecturers will be prepared to receive such members of the Congress as may desire to visit these hospitals and to inspect their schools and museums. *2 to 3.30 p.m.:* Additional meeting time for the sections. *4 to 5.30 p.m.:* Third general meeting, theatre of the University of London. Address by Dr. Billings, Washington, U.S., on "Our Medical Literature." *9 p.m.:* Conversazione at the Royal College of Surgeons.

Saturday, August 6th, 10 a.m. to 1 p.m.: Sectional meetings. *4 to 7 p.m.:* Reception of a certain number of the members at Kew Gardens by Sir J. D. Hooker. *4 to 7 p.m.:* A garden party will be given by Mr. and Mrs. Spencer Wells, at Golder's-hill, Hampstead. *6.30 p.m.:* The United Hospitals Club will entertain a party of the members of the Congress at dinner at the "Star and Garter," Richmond-hill.

Sunday, August 7th, 10 a.m.: A service will be held in Westminster Abbey; sermon by the Very Rev. Dean Stanley, D.D., F.R.S. *3.15 p.m.:* A service will be held in St. Paul's Cathedral; sermon by the Rev. Canon Liddon, D.D., D.C.L. *2 p.m.:* The Royal Botanic Society's Gardens and the Gardens of the Zoological Society, in the Regent's-park, will be open free to members on this and on every day of the week on presentation of their tickets. The Royal Gardens at Kew may be visited on Sunday from 9 A.M. till sunset, and Hampton Court Palace and Gardens from 2 P.M. till sunset.

Monday, August 8th, 10 a.m. to 1 p.m.: Sectional meetings. *2 to 3.30 p.m.:* Additional meeting time for sections. *4 to 5.30 p.m.:* Fourth general meeting, theatre of the University of London; address by Professor Volkmann, Halle. *6.30 p.m.:* Dinner given to a certain number of the foreign members of the Congress by the worshipful master and wardens of the Society of Apothecaries in their hall in Blackfriars. *9 p.m.:* Soirée in the Albert Hall, and the International Medical and Sanitary Exhibition, South Kensington.

Tuesday, August 9th, 10 a.m. to 1 p.m.: Sectional meetings. *2 p.m. to 3 p.m.:* Fifth general meeting, theatre of the University of London. Address by Professor Huxley, F.R.S., D.C.L., London, "The Connexion of the Biological Sciences with Medicine." *3 p.m.:* Concluding meeting of the Congress.

After the concluding meeting the members, accompanied by their friends, will proceed to Victoria Station, for High Level Station (London, Chatham, and Dover Railway), where special trains will be in waiting at four o'clock, to convey them to the Crystal Palace. After a visit to the palace and grounds, an informal dinner will take place in the concert room about seven o'clock.

Places of interest may be visited by members of the Congress, on conditions which can be ascertained at the office of the Reception Committee.

EXCURSIONS.

Friday, August 5th, 12.45 p.m.: Mr. John Penn will receive a certain number of the members of the Congress on board a special steamer at Charing-cross pier, in order to proceed down the river to Greenwich, and after luncheon there with Mr. Penn to visit the engine works of the Messrs. Penn, returning either by water or rail to Charing-cross.

Saturday, August 6th, 2 p.m.: Excursion to Folkestone. A certain number of members will leave Charing-cross Station by special train, provided free of cost by the South Eastern Railway Company, to witness the unveiling of the Harvey memorial-statue. After the ceremony the Mayor and Corporation of Folkestone will entertain the visitors at a banquet in the Town-hall. *2 p.m.:* Excursion to Hampton Court. Under the guidance of Dr. Langdon Down a party will visit Hampton Court Palace and Gardens, proceeding thence by river to Hampton Wick, where they will be entertained by Dr. Down at a garden-party at his residence, Normansfield. The members can reach Hampton Court either by the road, the river, or the rail. A special train will leave Waterloo Station (South Western Railway) at 2 o'clock.

Sunday, August 7th, 1.30 p.m.: Excursion to Boxhill. A special train will leave Victoria Station (Brighton and South Coast Railway) for Boxhill. At Burford Lodge, close to the station, Sir Trevor Lawrence, Bart., M.P., will receive a party of the members of the Congress at luncheon. The train will return from Boxhill to London at 6 P.M.

Monday, August 8th, 11 a.m.: Visit to the Docks, under the guidance and hospitality of Sir George Chambers, chairman of the London, St. Katherine's, and Victoria Dock Company. A limited number of members will proceed to St. Katherine's Dock House on Tower-hill at 11 A.M., where the indigo and tobacco floors will be inspected, and, in the adjoining London Dock, the ivory, drug, spice, and wool floors, and also the largest wine vault. From the Shadwell basin a steamboat will then take the party, for whom Sir George Chambers will provide luncheon on board, down the river to the Victoria Docks. Having passed through the Royal Victoria and Royal Albert Docks, the party will return by the river to Charing-cross pier.

WILLIAM MAC CORMAC, Honorary Secretary-General.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Monday several petitions were presented on the subject of vivisection, some praying for an alteration of the law regulating the practice, others for its total abolition.

In the House of Commons on Thursday, the 9th inst., on the motion of Mr. Dodson, a copy was presented of the memorandum of Dr. Buchanan, medical officer of the Local Government Board, on the present prevalence of small-pox in London among vaccinated and unvaccinated persons respectively.

The Artisans' Dwellings Acts.

On the motion of Sir R. Cross, the Select Committee on the working of these Acts was appointed as follows:—Mr. Courtney, Sir Sydney Waterlow, Sir Matthew Ridley, Mr. William Holms, Mr. Brodrick, Mr. Torrens, Sir Henry Holland, Mr. Bryce, Sir James M'Garel Hogg, Mr. Cropper, Viscount Emlyn, Mr. Francis Buxton, Mr. Arthur Balfour, Mr. Hastings, Mr. Rankin, Mr. Brand, Mr. Leamy, The O'Donoghue, and Sir Richard Cross.

Prevention of Floods.

On Friday the Select Committee on the Rivers Conservancy and Prevention of Floods Bill was nominated as follows:—Mr. Dodson, Mr. Sclater-Booth, Mr. Peel, Mr. Harcourt, Sir Andrew Fairbairn, Mr. Reginald Yorke, Mr. Arthur Arnold, Mr. Fellowes, Sir Robert Cunliffe, Mr. Compton Lawrance, Lord Edward Cavendish, Mr. Pell, Mr. Arnold Morley, Sir Rainald Knightley, Mr. Magniac, Mr. Stanhope, Lord Edmond Fitzmaurice, Mr. Levett, Mr. Hibbert, Mr. Pugh, and Mr. Arthur Balfour. Mr. Stanhope moved that the Committee have power to take evidence, but this was opposed by the Government on the ground that it would prevent the Bill passing this session, and on a division the motion was rejected by 116 to 63. The River Floods Prevention Bill was referred to the same Committee, as also were all petitions for or against either Bill.

London Fish Supply.

The following question was put down for Thursday:—Mr. Firth, to ask the Secretary of State for the Home Department whether he has yet received a reply to the letter addressed by him to the Lord Mayor in reference to London fish supply; whether he is able to communicate the tenor of such reply to the House; and whether, in case such reply is not satisfactory, he is prepared to initiate or suggest any measures for the improvement of the facilities and increase of supply of this important article of food.

Overworking Telegraph Clerks.

Lord Randolph Churchill will on Monday ask the Postmaster-General whether his attention has been called to the case of a telegraph clerk in the western district, who, in consequence of overwork, has become temporarily incapacitated from duty owing to mental derangement.

Dr. Cameron has secured the first place on the paper for Friday evening, July 8th, to call attention to the lack of capacity and resource displayed by the Local Government Board in dealing with the small-pox epidemic in London.

Dr. Farquharson will move the rejection of the Vivisection Abolition Bill, which stands for reading on Wednesday, July 13th.

The Contagious Diseases Acts.

Mr. Hopwood asked the Secretary of State for the Home Department whether it was the fact that three surgeons, acting under the Contagious Diseases Acts in the examination of prostitutes, had been appointed justices of the peace for the boroughs of Portsmouth, Windsor, and Southampton, respectively; would he give the dates of appointment; did these persons act as magistrates to enforce the Acts which they administered as officers; did they so act in court, or by private order; if so, was the right of appeal to a justice of the peace, which is given by the Acts in question to unfortunate women, secured to them; and would he intimate to these persons that they must make election between the duties of examining surgeons and justices.—Sir W. Harcourt said he had inquired into the matter, and received letters from the gentlemen in question. They were surgeons and justices of the peace. He would not trouble the House with the letters; but all three gentlemen stated in the most explicit way that they did not act as justices of the peace in any case connected with the Contagious Diseases Acts, and that they would think it highly improper on their part to do so.—In reply to Mr. O'Kelly, Mr. Forster stated that it was not intended to apply the Contagious Diseases Acts to Dublin.

Small-pox at Gravesend.

Mr. Findlater asked the Secretary of State for the Home Department if his attention had been called to the fact that small-pox having broken out in a street of small tenements in the borough of Gravesend, the medical officer of health made an application to the Mayor to get a magistrate's order for the removal of several fresh cases to certain huts which were last year built in an isolated country locality for the reception of those suffering from any contagious disease, which application was refused by his worship; and if the chief magistrate was justified in such refusal; and, if not, whether the Government would take steps to prevent a repetition of such refusal.—Sir W. Harcourt said he had received a telegram from the Mayor of Gravesend stating that an application was made under the 12th section of the Act of 1875, which only authorised the removal of children when they were without proper lodging and accommodation, and the magistrates, after considering the circumstances, did not think the case came within that section.

Mr. Warton has given notice of his intention to move the rejection of the Lunacy Law Assimilation (Ireland) Bill. On the order for going into Committee on the Infectious Diseases Notification (Ireland) Bill, Dr. Lyons will move to refer the Bill to a Select Committee.

On Monday, a petition was presented from the vestry of St. Pancras in favour of the Lunacy Law Amendment Bill.

The Alkali Bill.

In Committee on the Alkali &c. Works Regulation Bill, Major Nolan moved to exempt Ireland from the Bill, except as regards Dublin and other towns of 50,000 inhabitants. This was rejected by 140 to 16. Mr. Boord moved to include tar works in the schedule. Mr. Dodson replied that the Royal Commission indicated no means of dealing with tar works except simple inspection, and therefore they were not included in the Bill. Neither were some other kinds of works, in connexion with which no remedy had been discovered; but he hoped and believed that, in process of time, as remedies were discovered, the proprietors of those works would request that they should be added to the schedule of the Act. This answer being deemed unsatisfactory, a division was taken. Mr. Boord was followed into the lobby by 40 members, but the Government had 68 supporters, and the motion was consequently defeated. Earl Percy subsequently moved to include works for the manufacture of coke, lead, spelter, cobalt, &c., urging that they should be brought within the scope of the Bill, in anticipation of remedies being discovered; but the motion was negatived without a division, and the Bill passed the stage of committee, and was reported to the House amidst cheers. Mr. Callan and Mr. Biggar subsequently put down notices hostile to the Bill for the next stage.

Fines for Non-Vaccination.

On Tuesday, on the motion of Mr. Courtney, an address was agreed to for "an amended return to the Address of the Honourable the House of Commons, dated the 1st day of August, 1879, for 'returns showing the number of persons who have been imprisoned or fined for non-compliance with the provisions of the Act relating to the Vaccination of Children, distinguishing imprisonments and fines, the length of imprisonment undergone by such persons, the number of times any person has been imprisoned being more than once;

and of the number and amount of fines paid by any person who has been fined more than once for the above-mentioned offence.'"

Small-pox Hospitals.

On the motion of Mr. H. H. Fowler, a return was ordered showing the number of hospitals, whether temporary or permanent, provided for small-pox patients, under Section 37 of "The Sanitary Act, 1866," by the vestries and district boards in the metropolis, the situation of such hospitals, the year in which they were established, the number of patients which they are capable of accommodating, and the actual number of patients therein on the 13th day of June, 1881.

The Case of Thomas Titley.

Mr. H. B. Sheridan, put down for Tuesday, July 12th, his motion with regard to this case, as follows :—"That, in the interests of public morality, and for the protection of the constitutional rights of the people of this country, it is desirable that the police constables and all who aided and abetted them in the conspiracy to induce Thomas Titley, chemist, to commit the offence for which he is now suffering imprisonment, be forthwith prosecuted by the Public Prosecutor."

On Wednesday, a batch of petitions were presented in favour of the repeal of the Contagious Diseases Acts. Mr. Stansfeld's Bill, however, which stood for second reading to-day, was withdrawn, pending the report of the Select Committee.

Maintenance of Irish Lunatics.

The following notice was given for Thursday, 23rd inst. :—Mr. O'Shaughnessy, to ask the Chief Secretary to the Lord Lieutenant of Ireland, if he can hold out any hope that in allocating the cost of non-paying lunatics in Irish Lunatic Asylums the executive will, in cases where the district of the Asylum includes a county and a county of a city, so exercise the powers given it by statute as to avoid throwing on either portion of the district, exclusively of the other, the cost of non-paying lunatics who have been but a short time residing in such first-mentioned portion of the district ; and whether he will consider the advisability of so exercising the aforesaid powers as to follow, between such portions of such district, the analogy of the law regulating the liability of different electoral divisions in the same union for the cost of the relief of in-door paupers.

Correspondence.

"Audi alteram partem."

WHO'S RIGHT, AND WHO'S WRONG?

To the Editor of THE LANCET.

SIR,—The old saying that there are even educated men who live in the world and not with the world, from failing alike to perceive the tendency of the age in which they live, and to apreciate the changes ocuring around them, apears to me to be admirably ilustrated by a leter which apeared in your journal of to-day from Mr. John Chippendale, headed "Dr. George Harley's Cacography," in which he biterly complains of the "great shock" I caused to his feelings by my having had my article on the "Germ Theory of Disease" printed without encumbering its words with useles duplicated consonants.

When Mr. Chippendale's leter is carefuly read, however, it becomes aparent that he is unaware of the fact that Speling Reform Asociations are rapidly springing up, both at home and abroad; that bishops and archbishops countenance them; that we are already on the eve of a great national speling reform movement; that what we were taught at school about English words being, as a rule, spelt upon etymological principles has been discovered to be contrary to fact, except in the case of technical terms, &c. In spite of the risk of giving a stil greater shock to Mr. Chippendale's sensitive nature, I wil venture to give him one or two glaring instances where English speling is not consonant with, *but contrary* to, etymological principles. Let me tel him, for example, that a "Jerusalem artichoke" has nothing whatever to do with the Holy Land, but gets its name—though certainly not its speling—from the Italian girasole! That Pegwel Bay Sandfire is even not corectly etymologicaly spelt when writen as Sampire, as it is a mere English coruption of the French noun for it—St. Piere. That his friend, the old lady's wig, has no conexion whatever with the "wigings" of his school days; but has actualy the marvelous audacity to be derived from "pileus," the Roman freeman's hairy cap. That the tawdry of his sculery maid comes directly from the dignified St. Aubrey; and so I might go on with endles variety of comon words to disprove Mr. Chippendale's asertion, but I wil merely recomend him to send 5*s.* to the Speling Reform Asociation, 20, John-street, Adelphi, and get the last year's number of its Journal, and also procure a copy of my book on the "Simplification of English Speling," published by Trübner & Co. at 2*s.* 6*d.*, as wel as the leter on "National Speling Reform" I adresed to the late Prime Minister, which Hodgson & Co. published in the shape of a sixpeny pamphlet; for I think it is a pity that when Mr. Chippendale feels himself reluctantly forced to break his wise resolution not to rush into print every time his eyes fal upon views not in exact acordance with his own, he should be so unfortunate as to do more injury to his own literary reputation than to his oponent's. I should advise him to console himself in future with the reflection that there is sound wisdom in the old German proverb which says, "Speech is silver; *silence* is gold."

In conclusion, although I dare not say that I feel pleased at having had the trouble forced upon me of replying to an inconsiderate leter, in order to prove that I bear no malice to its *wel meaning* author, I shal give him, as a parting gift, a piece of information which wil probably act as a sort of soothing plaster to his iritated feelings—namely, that the omision of duplicated consonants, while it in no wise detracts from the beauty of our language, has the imense advantage of saving much manual labour to literary men, and money to publishers. In proof of this I may tel him that it has been calculated—not by me, however—that by omiting duplicated consonants *The Times* newspaper would, in space, labor, and materials, efect a saving equal in amount to £10,000 a year!—Yours faithfully,

Harley-street, W., June, 1881. GEORGE HARLEY.

PHTHISIS AND HYDROPATHIC ESTABLISHMENTS.

To the Editor of THE LANCET.

SIR,—Struck by the singular heading to a letter in your issue of May 28th, I read and ultimately was able to identify the case referred to, and would now, with your permission, make a few additions from my case book to its clinical history.

W. O—— came on June 19th, 1880. A commercial traveller, aged twenty-five, but looking older, well developed, but yellow and tremulous. Had slight pain at the sternum ever since a fall while skating in January last, but paid no attention to it, until two or three weeks before a swelling appeared to the right of the sternum, and was the size of a hen's egg and pointing. For some time he had been perspiring excessively and losing weight, as much as 4 lb. in one week a fortnight ago; pulse 76; tongue flabby and covered with a whitish-yellow fur, bowels costive, urine frequently loaded with lithates; appetite good, but often bilious. Beer makes him ill, but he takes wines and spirits freely and smokes to excess. Treated as Dr. Williamson relates, improvement is recorded at each weekly consultation, until on July 23rd—in five weeks, not ten—he left "cured," according to the entry in the register of cases.

On September 22nd he returned, reporting himself as very well in health, with the exception of a small fistulous opening at the lower end of the manubrium sterni, discharging a little serum. In a few days he left again, not returning for three months, when (November 20th) he came with an abscess pointing rather higher; the tongue coated as at first; bowels costive; pulse 88, and weak; and much reduced in condition. This relapse, so far from showing a too faithful an adherence to dietetic restrictions, as Dr. Williamson would suggest, had followed on a return to the free living of "the road," the patient having meanwhile become strong and well enough to resume travelling. The liberal use of beer, wines, and spirits was owned to, also smoking to excess and taking late suppers. This visit was brief.

These particulars must be allowed to detract somewhat from the typical character Dr. Williamson would attribute to the case, admitting as they do of a very different interpretation or moral from that advanced in his letter.

To keep up the strength under such circumstances is, of course, of great importance, but not less so is it to get the digestive organs right and the blood pure; and that the free exhibition of fat and oily foods was here contra-indicated, appears plainly from the improvement coincident with their restriction (not total prohibition). I regret much to find that through a mischance to the records of weight for that period, I cannot give the details of the improvement in nutrition implied in the result recorded.

Had the patient got worse during those five weeks of dieting and treatment instead of better, and had he improved on resuming a "liberal diet" later on, instead of relapsing, or had the result under Dr. Williamson's care been the opposite of that he unhappily has to record, the grounds of his conclusions would have been much better and the opposite opinion less tenable.

The case in some important particulars is unsatisfactory, and the absence of evidence of syphilis, or hereditary tuberculosis, may justly be held to lay increased responsibility on its management in the endeavour to account for the final result; but it is not unreasonable to suppose in view of its earlier history that the mode of management which answered so well at first might, if persevered in, have continued to do so, and permanent recovery secured. Errors there may have been—at Matlock or even at Ventnor, as elsewhere,—but when one undertakes to expose the shortcomings of another, he should at least be careful to ascertain all the facts, and should not let the sweep of his censure, if censure is meet, be wider than the facts warrant.

I am, Sir, yours faithfully,

Matlock, June 6th, 1881. W. B. HUNTER.

REMOVAL OF THE KIDNEY.

To the Editor of THE LANCET.

SIR,—In your issue of June 4th I observe the interesting account of "Removal of the Kidney for Nephrolithiasis." As you observe, this is not the first operation of its kind. The object of my present communication is twofold.

1st. To modestly point out that I believe I had the honour of first bringing this subject forward in England in an original paper, based upon experiment on rabbits, and read before the Pupils' Physical Society of Guy's Hospital, and for which I was awarded the first prize in 1869. The preparation for that paper (experiments, &c.) had occupied a great deal of my time for about eighteen months previously.

2nd. To notice its bearing upon vivisection. Now, throughout all those experiments (they were many, and all successful) I always placed the animal under chloroform, and spared no trouble to avoid pain. When the evening arrived for my paper I had many of my "victims" present to prove, if necessary, the success of the operation, but in deference to the expressed wish of the great number of my fellow students, who were assembled there at the time, I killed only *one* rabbit for a post-mortem demonstration, and yet in the face of this and other humane sentiments the public is apt to look upon the medical student as a hard-hearted wretch. I never found one to be so. But "good-bye" to experiments unless you happen to be one of the few privileged and licensed operators. Had the law for vivisection been in force at the time I should not, in all probability, be commenting on my paper on "Nephrotomy and Excision of the Kidney" now. Yours faithfully,

Trinity-square, S.E., June 7th, 1881. F. G. LARKIN.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 9th:—

Barton, Wm. Edwin, Shogswell Manor, Etchingham.
Bate, Henry Hele, Plymouth.
Braga, Joas Francisca, Bernard-street.
Prentice, Zacharia, Canterbury.
Smith, Gilbert Thomas Smith, Richmond-crescent.

The following gentlemen also on the same day passed the Primary Professional Examination:—

William Hamilton Hart, Guy's Hospital; Arthur Thos. Holdsworth, Queen's Hospital, Birmingham; Richard Pritchard Roberts, University College; Edward Tull Trevor, Guy's Hospital.

THE salary of Dr. Reid, Assistant Physician to the Royal Lunatic Asylum, Aberdeen, has been increased from £120 to £150 per annum.

THE BRITISH ASSOCIATION.—It has been resolved at a meeting of representatives of various educational institutions held in Birmingham, to invite the British Association to hold their annual meeting for 1883 in that town.

DR. SAMUEL CROMPTON, Consulting Physician to the Salford Royal Hospital and Dispensary, has presented a valuable collection of medical books to the committee of the Bolton Infirmary.

A MOVEMENT has been started to obtain subscriptions for the purpose of erecting a suitable memorial stone over the grave, in Allenvale Cemetery, of the late Dr. James Simpson, of Aberdeen.

THE proceeds of "Ye Old English Fayre," held last week at the Albert Hall, will, it is stated, enrich the funds of the Chelsea Hospital for Women to the extent of about £7540. The fair was revived by Mr. J. S. Wood, the secretary, under the title of "A graunde Fantesie Fayre and Olde Englysh Cheape," at Bolingbroke House, Wandsworth-common, on the 16th, 17th, and 18th inst., for the Bolingbroke House Pay Hospital.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. H. W. Eyres, late of Grosvenor-street, bequeathed £250 to the Leeds General Infirmary. Mr. James Farrar, late of Halifax, Yorkshire, bequeathed £500 to the Halifax Infirmary and Dispensary. The National Hospital for Consumption, Ventnor, has received a legacy of £1000, free of duty, from the late Major C. S. Barron, and one of £300, less duty, from the late Miss Martha Relfe.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—On Whit-Monday the following office-bearers were elected for the ensuing year:—President: Samuel Chaplin. Vice-President: John Kellock Barton. Secretary: William Colles. Council: Wm. Colles, Alfred H. McClintock, George H. Porter, George H. Kidd, William A. Elliott, T. Jolliffe Tufnell, Edward Hamilton, Rawdon Macnamara, Robert McDonnell, Edward D. Mapother, Archibald H. Jacob, Edward Hallaran Bennett, Philip Crampton Smyly, John Denham, Anthony H. Corley, William Stokes, Henry R. Swanzy, W. T. Stoker, and William J. Wheeler. One hundred and six Fellows voted at the election.

IRISH MEDICAL ASSOCIATION.—The following office-bearers have been elected for the ensuing year:—President: John T. Banks. Vice-Presidents: Parsons Berry, Bellew Kelly, William Miller, and H. O'Farrell. Council: J. Wallace Boyce, Robert Browne, J. H. Chapman, H. G. Croly, Thomas Darby, Thomas Drapes, Alexander Filson, R. Gray, J. R. Harvey, Robert Hayes, A. Jacob, David Jacob, George H. Kidd, Richard John Kinkead, James Martin, R. McDonnell, F. V. McDowell, James Maloney, G. Morrogh, Andrew Nolan, C. Norman, William Perceval, James F. Pollock, George H. Porter, Thomas Purcell, J. Ridley, Edmund P. Sharkey, H. J. Smith, John Spencer, Robert Tagert, W. Thomson, and John Lennon Walshe. Auditors: Albert Croly and H. C. Tweedy. Hon. Secretary: Albert O. Speedy.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

BARKER, H. M., M.B., M.R.C.S.E., L.R.C.P., has been appointed Medical Officer and Public Vaccinator to the Brading District of the Isle of Wight Union, vice C. Meeres, resigned.

BIRCH, G., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Hackney Union, vice Long, resigned.

CHESHIRE, Mr. H. F., has been appointed Public Analyst for the Borough of Rye.

COOKE, E. M., M.B., M.R.C.S.E., has been appointed Medical Superintendent of the County and City of Worcester Lunatic Asylum, Powick, vice Sherlock.

COOPER, W., M.R.C.S.E., L.S.A.L., has been elected House-Surgeon to the Croydon General Hospital, vice T. T. Newman, L.R.C.P.L., M.R.C.S.E., resigned.

DEANE, E., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer to the Second District of the Shepton Mallet Union.

EADON, W. F. B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Fifth District of the Barton Regis Union.

FOSTER, N. S., M.D., C.M., has been appointed Medical Officer to the Stoke Lyne District of the Bicester Union.

GAMGEE, J. S., F.R.S.Ed., M.R.C.S.E., has been appointed Consulting Surgeon to the Queen's Hospital, Birmingham.

HAMILTON, R., M.B., C.M., has been appointed Medical Officer for the Rytherwith Ozendike District of the Tadcaster Union.

HILLIARD, H. C., M.D., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Caterham District of the Godstone Union.

HOPE, E. W., M.B., B.Sc., L.R.C.P.L., has been appointed Resident Medical Officer to the Netherfield Fever Hospital, Liverpool, vice W. Rushton Parker, B.A., M.B., M.R.C.S.E., resigned.

JACK, J. S., M.B., C.M., has been appointed Medical Officer to the Rothbury East District of the Rothbury Union.

JONES, J. D., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Shebbear District of the Torrington Union.

MARSH, T. A. P., M.R.C.S.E., L.R.C.P.L., has been appointed House-Surgeon to the Weston-super-Mare Hospital, vice Rowlands, resigned.

MAY, B., M.B., F.R.C.S.E., has been appointed Honorary Surgeon to the Queen's Hospital, Birmingham, vice Gamgee, resigned.

MOORE, Mr. E. H., has been reappointed Public Analyst for the Western Division of the County of Sussex.

SHEMILT, G. R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Third District of the Highworth and Swindon Union.

SMITH, C. R., M.B., M.R.C.S.E., has been appointed Surgeon to the Eye Infirmary, Wolverhampton.

THOMSON, A., M.B., C.M., has been appointed Assistant Medical Officer to the Montrose Royal Lunatic Asylum, vice W. J. Dodds, M.D., resigned.

WATTS, T. F., M.B., C.M., has been appointed Assistant Medical Officer to Her Majesty's Prison *Walton*, Liverpool.

Births, Marriages, and Deaths.

BIRTHS.

BIRCH.—On the 8th inst., at Sussex House, Downs-road, Lower Clapton, the wife of George Birch, Esq., M.R.C.S.E., of a daughter.

CHARLES.—On the 7th inst., at West Cromwell-road, South Kensington, the wife of T. Cranstoun Charles, M.D., of a son.

DUKE.—On the 15th inst., at 1, Cavendish-terrace, Clapham-common, the wife of Benjamin Duke, M.R.C.S.E., of a daughter.

EAGER.—On the 14th inst., at the County Asylum, Melton, Suffolk, the wife of Wilson Eager, Medical Superintendent, of a son.

IRONSIDE.—On the 7th inst., at Highbury New Park, the wife of R. A. Ironside, M.B., of a son.

NICHOLLS.—On the 2nd ult., at Dominica, West Indies, the wife of H. A. Alford Nicholls, M.D., of a daughter.

RICE.—On the 5th inst., at Friar-gate, Derby, the wife of George Rice, M.R.C.S.E., of a son.

MARRIAGES.

BIRD—FREELAND.—On the 9th inst., at All Saints', Paddington, Peter Hinckes Bird, F.R.C.S., F.L.S., of Norfolk-square, W., to Rosa M. Freeland, of Ovington-gardens, South Kensington.

CLARKE—ALEXANDER.—On the 8th inst., at Glasgow, Henry J. Clarke, M.B., C.M., M.R.C.S.E., of Doncaster, to Isabella Margaret, youngest daughter of T. Alexander, Esq., of Glasgow.

FORSYTH—RAYNER.—On the 8th inst., at the Parish Church, Birstall, by the Rev. John Kemp, M.A., Vicar, assisted by the Rev. F. T. White, M.A., Curate, Robert Adam Forsyth, M.D., to Annie Marguerita, younger daughter of Robert Rayner, Esq., M.R.C.S.E., of Newstall, Birstall.

MORGENROOD—REID.—On the 8th inst., at Anerley Congregational Church, William George Morgenrood, M.B., C.M., L.R.C.S., &c., second son of Philip D. Morgenrood, of Wynberg, Cape of Good Hope, to Jessie Wardlaw, second daughter of William Wardlaw Reid, of Selhouse Park, South Norwood.

MUIR—BOSCAWEN.—On the 8th inst., at Marchwiel Church, Denbighshire, James Claudius Pollock Muir, L.R.C.P.Ed., L.R.C.S.Ed., to Isabella Nina, eldest daughter of the Rev. W. H. Boscawen, Rector of Marchwiel, and Rural Dean.

DEATHS.

GIBBON.—On the 2nd inst., at Pevensey-road, St. Leonards-on-Sea, Anne, widow of the late James Gibbon, M.D., of Windsor Lodge, Swansea, and daughter of the late Rev. Robert Wynter, Rector of Penderyn, Breconshire, aged 86.

JONES.—On the 15th inst., at his residence, Sydenham-park, Edward Jones, M.D., aged 66.

MATTHEWS.—On the 3rd inst., at his residence, The Acacias, Dovercourt, Arthur Matthews, M.R.C.S.E. (formerly of Robertsbridge, Sussex), aged 75.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths*

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

NOMINATION COMMITTEE.—Sir JAMES PAGET, Bart., Chairman.

THE Committee, consisting of Messrs. Birkett, Savory, Marshall, Wood, Forster, Hutchinson, the President, and the Vice-Presidents, in pursuance of the resolution of the Council of the 13th ultimo, have taken into consideration the regulations under which the committee shall act in nominating candidates for election to College Examinerships, and have agreed to the following recommendations :—

I. Constitution and Duties of the "Nomination Committee."—1. The Nomination Committee shall consist of seven members of the Council, together with the president and vice-presidents, and not less than three members of the committee shall be, or shall have been, members of the Court of Examiners. 2. The duties of the Nomination Committee shall be as follows :—(*a*) To consider applications from candidates for the offices of Examiner in Anatomy and in Physiology, in Medicine, in Midwifery, and for the Dental Section of the Board of Examiners in Dental Surgery ; to report thereon to the Council ; and to recommend the candidates deemed fittest for election. (*b*) To be visitors of the examinations in Anatomy and Physiology, in Medicine, in Midwifery, and in Dental Surgery. (*c*) To make representations and recommendations to the Council respecting the aforesaid examinations. 3. The members of the Council appointed members of the Nomination Committee shall be ineligible for any of the before-mentioned examinerships.

II. Notices respecting Elections, and Mode of Election of Examiners.—1. Notice of intending elections to the examinerships shall be advertised in medical journals not less than one month prior to the date of those elections ; and candidates shall be invited to send in their applications to the secretary not less than fourteen days prior to the date of election. 2. The secretary shall forward to each member of the Council a list of all the candidates applying for the office of examiner within seven days of the expiration of the period to which the application of candidates has been limited. 3. Every member of the Council shall receive notice of each meeting of the Nomination Committee for considering applications for the office of examiner, and shall be at liberty to nominate in writing to the secretary, before or at each such meeting, others than those applying as candidates for the said office. 4. The names of all candidates for the office of examiner, and the names of the candidates recommended by the Nomination Committee for the said office shall be inserted in the notice issued to the Council for the meeting appointed for the election.

III. Absence of Examiners.—1. In the event of any examiner being, through illness or any other unavoidable cause, unable to take part in any examination, the Nomination Committee shall be authorised, on behalf of the Council, to appoint a substitute for such examiner, reporting thereon to the next meeting of the Council.

IV. Number, Qualifications, and Duration of Office of Examiners.—1. The Board of Examiners in Anatomy and Physiology shall consist of nine members, to be appointed by the Council, to conduct the examinations in Anatomy and Physiology for the Membership and the Fellowship of the College. 2. The examiners in Anatomy and Physiology shall be elected annually from the Fellows of the College. 3. An examiner in Anatomy or in Physiology shall not hold office for more than five consecutive years, but after an interval of one or more years shall again be eligible for election. 4. The chairman of the Board shall be elected annually by the members of the Board, and shall be chosen from that section of the Board, either Anatomical or Physiological, of which the members shall at the time constitute the majority of the Board. 5. The four examiners in Medicine shall be chosen from the Fellows of the Royal College of Physicians, and shall be elected annually at the Quarterly Council in July. 6. An examiner in Medicine shall not hold office for more than five consecutive years, but after an interval of one or more years shall again be eligible for election. 7. The two examiners in Midwifery shall be chosen either from the Fellows of the College or from the Fellows of the Royal College of Physicians, and shall be elected annually at the Quarterly Council in July. 8. An examiner in Midwifery shall not hold office for more than five consecutive years, but after an interval of one or more years shall again be eligible for election. (N.B.—The regulation limiting the period of office for any examinership to five consecutive years may, upon special recommendation of the Nomination Committee and the approval of the Council, be suspended.) 9. A member or members of the Dental Section of the Board of Examiners in Dental Surgery shall, as provided by the by-laws, be elected from "persons skilled in dental surgery," and shall hold office "for the period of five years."

ERASMUS WILSON TRUST.

In pursuance of the resolution of the Council of March 10th, 1881, the president and vice-presidents have to report to the Council that they have taken into consideration the changes proposed in the Erasmus Wilson Trust, so as to provide that the proceeds of the fund shall be more advantageously employed than at present by appropriating them, in such proportion as the Council may from time to time determine, in part towards the payment of the salary of a pathological curator of the museum and in part for the payment of lectures or demonstrations on the pathological contents of the museum, to be given either by the pathological curator or some other person duly appointed for the purpose ; that they have consulted the legal adviser of the College on the subject, and, in accordance with his opinion, have instructed him to prepare a new deed, setting forth the objects of the Trust in its altered conditions, releasing the existing trustees from their obligations under the present Trust, and transferring to the College in its corporate capacity the observance of the conditions of the Trust so altered ; and that the new deed will shortly be ready for execution. The president and vice-presidents have further to report that, in view of the proposed changes, they recommend to the Council that all regulations at present in force relating to the Erasmus Wilson Trust be rescinded ; and that it be referred to the Museum Committee to inquire and report to the Council on candidates for the office of pathological curator of the museum, and on the regulations under which that office shall be held.

Medical Diary for the ensuing Week.

Monday, June 20.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ A.M. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

St. Mark's Hospital.—Operations, 2 P.M. ; on Tuesday, 9 A.M.

Royal College of Surgeons of England. — 4 P.M. Professor Jonathan Hutchinson, "On the Laws of Inheritance in Relation to Disease."

Tuesday, June 21.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 3 P.M.

Sanitary Institute of Great Britain.—8 P.M. Professor W. H. Corfield, "On the Present State of the Sewage Question."

Wednesday, June 22.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ P.M.

King's College Hospital. — Operations, 2 P.M., and on Saturday at 1 P.M.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 P.M.

University College Hospital. — Operations, 2 P.M., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children. — Operations, 2½ P.M.

Royal College of Surgeons of England.—4 P.M. Professor Jonathan Hutchinson, "On the Laws of Inheritance in Relation to Disease."

Epidemiological Society.—8 P.M. Mr. H. V. Carter, "Contribution to the History of the Epidemic Fever prevailing in the Country Districts of the Bombay Presidency during the Famine Period of 1876-78."—Mr. J. Mackie, "Report on Dengue Fever."—Mr. V. B. Barrington-Kennett, "On a System of Detached Floating Barracks for the Formation of a Small-pox or Fever Hospital."

Thursday, June 23.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—1½ P.M. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 P.M.

Central London Ophthalmic Hospital. — Operations, 2 P.M., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2½ P.M.

Friday, June 24.

St. George's Hospital.—Ophthalmic Operations, 1½ P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 2 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

Quekett Microscopical Club.—8 P.M. Mr. B. W. Priest, "On a New Species of Sponge from Honduras."

Royal College of Surgeons of England. — 4 P.M. Professor Jonathan Hutchinson, "On the Laws of Inheritance in Relation to Disease."

Saturday, June 25.

Royal Free Hospital.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Quacks in Japan.

There are, it appears (says the *Japan Weekly Mail*), no less than 65,200 doctors practising in Japan, of whom 504 only have received legitimate diplomas, and of these latter 50 are denizens of Tokiyo. It follows, therefore, that there are 64,696 individuals playing fast and loose with the lives of their fellow-creatures throughout the country—that is to say, an average of one quack to 470 quacked.

M. E.—We have no recollection of the paper.

A Fellow.—If our correspondent has not signed the by-laws he will not be allowed to record his vote. No opportunity will be afforded before the annual meeting.

Inquirer.—We should recommend our correspondent to address one of the professors at Netley.

DEATH FROM ETHER.

To the Editor of The Lancet.

Sir,—In view of the recent controversy, "Ether v. Chloroform," I think it specially desirable that untoward results should be published. I therefore send the account of a case of death from ether administration that recently came under my notice.

On the evening of March 8th I was requested by my colleague, Mr. Brummitt, to visit with him a case of diphtheria, he having tracheotomy in view for the urgent dyspnœa that was threatening life. We decided that the only chance was in operation, and I proceeded to administer ether. The patient, a girl of six years, somewhat mentally deficient and of delicate habit, was labouring for breath. The pulse was fair. I used a cage inhaler, putting into it about half an ounce of ether. The inhaler was at first held some three inches from the face, so as to gradually accustom the child to the vapour. It was by degrees approached closer, and then placed over the nose and mouth. There was a good deal of struggling, but the patient soon became quiet, and seemed to be getting comfortably under its influence. I reported her as nearly ready, and my colleague placed her in tracheotomy position. Having replenished the inhaler, I was proceeding with the administration when the breathing, which, though not very satisfactory, had been tolerably regular up to this moment, suddenly ceased. Artificial respiration was at once resorted to. The patient gave one gasp, and all efforts for restoration, though persevered in for some time, were unavailing; the heart could be felt feebly flickering for some two minutes after the breathing failed.

Having either administered or witnessed the administration of anæsthetics in several similar cases, it seems conclusive that their use in such is attended with more than ordinary risk. In one in which chloroform was used the patient died as soon as the operation was completed; but as the child was almost comatose at the commencement, it is perhaps hardly fair to attribute the result to the anæsthetic. In two others ether was used, and the danger appeared imminent.

Should I again have to produce anæsthesia in similar cases, I think I should give chloroform the preference. Ether is supposed to cause death by paralysing the respiratory powers. In laryngeal diphtheria these are greatly overtaxed, consequently is not the danger increased by this anæsthetic? Another thing in favour of chloroform is that there is usually less struggling when it is used. In employing these agents in cases where there is any respiratory obstruction it seems to me a good precaution to give the minimum quantity required to produce narcosis. In this particular instance the ether was from a sample which I have used a good many times without any unpleasant symptoms arising, and it seems remarkable that such a result should occur from so small a quantity.

I am, Sir, yours, &c.,

John J. Sangster, M.R.C.S., &c.

Burra, S. Australia, April 9th, 1881.

GOYDER'S CLINICAL STENCIL PLATES.

To the Editor of THE LANCET.

SIR,—I beg to thank you for the honour you have done me in noticing the above. Before the issue of the number for June 4th I was quite unaware of the fact that anyone had contemplated the use of stencilling in clinical work. The novelty I claim, however, is the combination of diagrams, and the plan of obtaining outlines of opposite bones and limbs by reversing the plate. May I be allowed to state also that the woodcuts published are one-half the actual size? I regret that in consequence of absence I have been unable to write this note sooner.—Apologising to you for the delay, I have the honour to be, Sir, yours very truly,

C. M. GOYDER,
Senior House-Surgeon,
June 14th, 1881. Newcastle-on-Tyne Infirmary.

SIMPLE METHOD FOR REDUCTION OF DISLOCATION OF SHOULDER-JOINT.

To the Editor of THE LANCET.

SIR,—In your issue of May 28th, Dr. S. R. Macphail calls attention to the ease with which dislocation of the humerus can, in most cases, be reduced by manipulation, and in doing so speaks of this method as if it were new, stating that although he "does not claim originality for it," it is a method "to which he has never seen any reference in the ordinary text-books." This is remarkable, when we notice that the method described by him is almost—if not altogether—identical with that described by Abernethy many years ago, called "Reduction by Stratagem," and the first-mentioned mode of treatment for luxation of the humerus, given in Bryant's "Practice of Surgery," second edition (1876). Mr. Bryant, however, here accompanies his description of reduction by this means with the remark, "To reduce a dislocation of the humerus by manipulation chloroform is essential." Whether this erroneous sentence is retained in the later edition of Mr. Bryant's admirable work I cannot say, not having it within reach.

Your correspondent will also find that Mr. Holmes, in his "Principles and Practice of Surgery," gives a short account of reduction by manipulation without mentioning chloroform in connexion therewith.

Reduction of the dislocated humerus by manipulation was—if my memory serves me aright—described in a minute and exhaustive manner by Professor Gordon of Belfast in a small work published six, eight, or more years since, entitled "Fractures of the Radius, &c."

Dr. Gordon describes different methods of procedure for the different forms of displacement, in order to avoid the ligamentous structures surrounding the joint, just as Bigelow does for the various dislocations of the hip, and teaches that the great majority of recent cases may be reduced by this method without the aid of an anæsthetic, and certainly in his hands it is almost always successful.

I have not Mr. Erichsen's work to hand, but would venture to say from memory that he also clearly describes manipulation as a frequently successful mode of reduction of the shoulder.

I am, Sir, yours very truly,
S. A. K. STRAHAN, M.D.
East Riding Asylum, June 1st, 1881.

Mr. Collier.—The list published by us last week is correct. Our correspondent had better communicate with the secretary of the College on the subject.

Messrs. Findlay and Co.—Curling or Allingham (Churchill) for diseases of the rectum; for intestines generally, Habershon.

"TEMPERANCE AND THE DOCTORS."

To the Editor of THE LANCET.

SIR,—This afternoon, in reading the current number of THE LANCET, I found a note bearing the above heading. Now, you will, I am sure, permit me to say that the short and imperfect reports of speeches and lectures found in newspapers sometimes convey the very reverse of what was really said, and the comments you are good enough to make on some speech attributed to me are very remotely applicable to anything I have ever said on the public platform, nor do they apply in any measure to anything I have ever said at Yeovil, seeing that I never in my life spoke at Yeovil, nor do I even know the name of the vicar of that town.

In justice to myself, I may surely add that I have on many occasions maintained that medical men have done much to check intemperance—more, indeed, than any other profession; and I have several times attempted to show that the members of the profession have not the comparative leisure of the clergy, nor the commanding authority and independent position of bishops, judges, and Ministers of State. This I think no one will deny; nor do so many men of rank and large fortune enter our profession as are found in one or two others.

Lastly, any remarks I may have made on three or four recent occasions that medical men are overworked and often underpaid, and not treated generally with the respect to which I have contended they are entitled, seem to me a defence of the profession, and in no sense an attack upon it. If the report of the speech in any way justified your comments, it certainly bears very small resemblance to any utterance of mine.—I have the honour to be, Sir, yours faithfully,

Wimborne, June 8th, 1881. ALFRED J. H. CRESPI.

⁂ We gladly insert our correspondent's letter. It would be well if he would write in correction of the report of his speech to the editor of the *Western Gazette*.—ED. L.

"ATTENDANCE ON CASES OF SUDDEN ILLNESS."

To the Editor of THE LANCET.

SIR,—People of all classes frequently labour under the delusion that a medical man can be compelled to attend at any time, especially in chance cases of midwifery. My experience has taught me that if he goes he will have to trust to providence for his fee.

People who take their sick to the hospital, &c., as out-patients, when they perceive danger, rush off at any hour to the nearest medical man, as they know a death certificate cannot be obtained from the officers of the institution, and probably they are too late to get an order from the parochial relieving officer.

Would it not be very satisfactory if people could have the privilege of calling in the aid of the first policeman to be found, and for him to give an order for immediate medical attendance, payable by the authorities as at present in cases of accident or sudden illness in the streets, and subsequently for the police to find out whether it was a case for the parochial medical officer?

I think such an order would be the means of preventing many unnecessary inquests, prevent many medical men from annoyance and low abuse, and, at the same time, a fair remuneration would be certain.

I am, Sir, yours faithfully,
G. D. HARDING, M.R.C.S., &c.
Lorrimore-street, S.E., May 28th, 1881.

THE HEADS OF THE PEOPLE.

To the Editor of THE LANCET.

SIR,—Hatters have discovered that the human head is decreasing in size. From practical experience they can testify that hats are made of a much smaller size at the present day than they were twenty-five or fifty years ago.

In a body of men like our soldiers and police the sizes run very small in many instances, although in these cases the men are often tall and well proportioned. The sizes of the heads of professors, doctors, &c., are always larger than those of the general public. Burns had a head 7¼ in. in size. Formerly the size of the hats sold was frequently from 7¼ to 7⅜ in., whereas now the average demand is for hats from 6¼ to 6⅝ in. What is the cause of this? Perhaps some members of the medical profession may be able to throw some light upon this important question. I am, Sir, yours truly,

Wolsey-road, N., June, 1881. W. H. SMITH.

A Young Practitioner.—1. Bristowe, Roberts, Tanner.—2. Barnes, Lombe Atthill.

CHLORAL v. STRYCHNIA.

To the Editor of THE LANCET.

SIR,—The following facts may be of some interest to your readers. On May 25th I found a pet fox-terrier bitch suffering from severe symptoms of strychnia poisoning. There were well-marked risus sardonicus and opisthotonos, with much rigidity of the limbs. She was lying on her side, totally unable to get up, and the respiration was 90 to the minute. I gave her immediately a draught of bromide of potassium and chloral (thirty grains of each), but owing to the spasmodic movements of the head, I failed to get it all down. I then gave her sixty grains of chloral (in crystals) on the tongue, and held her mouth until it was dissolved. She gradually went to sleep, and three hours after was able to walk, although with a good deal of weakness about the hind legs, and she has since gone on slowly to recovery.—I am, Sir, yours obediently,

Melton Mowbray, June 2nd, 1881. E. R. MANSELL.

A HINT TO CHLOROFORMISTS.

To the Editor of THE LANCET.

SIR,—When in Paris I was invited by Dr. Labbé to assist in a case of ovariotomy at a private hospital. The patient was given chloroform. When the anæsthesia was complete, the surgeon made his incision in the linea alba, through the skin and circular tissue. Suddenly the respiration stopped, and the heart ceased to beat, as clearly shown by the cessation of bleeding and the bloodless appearance of the lips of the wound. The mouth was cleansed from mucus, the tongue drawn forwards, the patient's head thrown well back, and artificial respiration was practised for quite ten minutes, but without result. The case appeared desperate, when Dr. Labbé put a large cloth in boiling water and applied it to the cardiac region. Instantly the heart commenced to beat and the patient to respire. She was saved. The operation was not terminated.

The cloth which had been applied was of such a heat that a large blister was raised at the seat of its application. Such simple and ever at hand means, which has succeeded several times with Dr. Labbé, may be unknown to a few of your readers, and possibly useful to all.

I am, Sir, yours &c.,
Great Russell-street, W.C., June 1881. ADOLFO PAGGI, M.D.

Dr. Davis.—The festival of the Fellows will take place the same evening at the Albion Tavern, when Mr. William Cadge of Norwich, a member of the Council of the College of Surgeons, will take the chair. Mr. B. T. Lowne is the honorary secretary.

Dr. M. W. Taylor (Penrith).—We shall be glad to receive the paper.

"THE COMMISSIONERS IN LUNACY AND ASYLUM REPORTS."

To the Editor of THE LANCET.

SIR,—No one of the leading men amongst asylum superintendents having noticed your annotation in THE LANCET of June 4th on the above subject, I venture to claim the favour of a little space for a few remarks.

The annotation in question indicates an extraordinary misapprehension of the case, and, with regard to private asylums at any rate, completely inverts the facts. The reports, it says, "have come to be nothing more or less than testimonials left with the authorities of asylums in return for the courtesy shown during an inspection." So far is this from fact that the key-note is rather that of blame than praise. The Commissioners have enormous power under the Lunacy Acts. They are apt to exercise it in framing their reports in a harsh, arbitrary, and capricious way. Proprietors of asylums are accused, convicted, sentenced, and punished without being arraigned, without means of defence, without opportunity of stating their case or rebutting unjust charges. It happens thus. The reports to which your annotation refers are crammed with frivolous complaints. These complaints are published in the Annual Blue Books. They become public property; newspapers extract them, and found upon them virulent attacks on private asylums. Authors quote them for the same purpose, as, for instance, Dr. Bucknill. This writer, eminent indeed, but *inops humanitatis atque inurbanus*, has in the sixth chapter of his work, entitled "The Care of the Insane," culled, without any attempt at comparison or contrast, a crop of these complaints from the Blue Book of 1875. He nowhere stops to inquire into the possible justice or injustice of the complaints. It is a clear case of the *argumentum ad populum*. However, let that pass. The point to be observed is that the use made in this and other instances of the complaints in question well illustrates the nature of the hardship which proprietors of asylums suffer. They are punished on mere accusation, without inquiry or proof. It is surely a punishment, and a very severe one, to be thus spitted in official documents, and to have the accusations published and ready to hand for anyone to extract and use at pleasure, and to cite as if they were fair and judicial condemnations.

The complaints, it must be remembered, are *ex parte* statements of visiting commissioners, prone by the nature of their office to fault-finding. When the statements get into the Blue Books there is no redress. The Board in Whitehall-place is inexorable, and there is no appeal. Asylum proprietors are far more harshly treated than the commonest and lowest publicans. Even they can claim to have their case heard. They may defend themselves in court. Before their licences are endorsed they are duly warned. Asylum proprietors' licences are endorsed without warning upon the mere *ipse dixit* of a couple of visiting commissioners, who may be by disposition capricious and harsh, or who may be suffering from indigestion or fatigue, or other causes of irritability, ruffled temper, and warped judgment. Surely no other class of men in the kingdom is placed under so arbitrary a rule as private asylum proprietors, or one so severely administered. Your annotation, therefore, as far as regards them, is erroneous and misleading.

These remarks are strictly limited to private asylums. The superintendents of public asylums have perhaps a good answer to give. If so, let them give it themselves; let them state their own case.

"Herr gib Regen und auch Sonnenschein
Für Reitz, Kreitz, und Lobenstein
Woll'n die Andern auch was ha'n
Soll'n sie dir es selber sa'n."

I am, Sir, yours, &c.,
June 14th, 1881. G. F. BODINGTON.

"THE BLOOD OF SAINT JANUARIUS."

To the Editor of THE LANCET.

SIR,—In vol. i., p. 301, of Salverte's "Philosophy of Magic, Prodigie and Apparent Miracles," translated by Anthony Todd Thompson, M. Lond., is given the following account of the apparent miracle :—"In th present day, at an annual public ceremony at Naples, some of the blo of St. Januarius, collected and dried centuries ago, becomes spont neously liquefied, and rises in a boiling state to the top of the phial tha encloses it. These phenomena may be produced by reddening sulphur ether with orcanette [alkanet root] (*onosma*, Linn.), and mixing the tin ture with spermaceti. This preparation, at ten degrees above the free ing point (*Centigrade*) [F. 50°] remains condensed, but melts and boils a twenty [F. 68°]. To raise it to this temperature it is only necessary t hold the phial which contains it in the hand [or near a lighted lamp] fo some time. If a little simple jugglery be combined with this philoso phical experiment, the apparent miracle is complete."

I am, Sir, yours, &c.,

ON HOSPITALS:

THEIR MANAGEMENT, CONSTRUCTION, AND ARRANGEMENTS IN RELATION TO THE SUCCESSFUL TREATMENT OF DISEASE, WITH REMARKS ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS.

By FREDERIC J. MOUAT, M.D., F.R.C.S.,

FORMERLY PROFESSOR OF MEDICINE, CLINICAL MEDICINE, AND MEDICAL JURISPRUDENCE IN THE MEDICAL COLLEGE OF CALCUTTA, AND FIRST PHYSICIAN OF THE HOSPITAL ATTACHED TO THE COLLEGE; DEPUTY INSPECTOR-GENERAL OF HOSPITALS (RETIRED); VICE-PRESIDENT AND FOREIGN SECRETARY TO THE STATISTICAL SOCIETY OF LONDON, ETC.

(*d*) DISTRIBUTION AND DIMENSIONS OF BUILDINGS AND WARDS.

In all the most recent hospitals of Germany, France, the United States, and Scotland, and in several of our great Poor-law infirmaries, the pavilion plan has been adopted for the sick wards, and all accessory and administrative buildings are more or less completely separate from them. In some the blocks of all kinds are absolutely detached, without connecting corridors of any kind (Friedrickshain in Berlin, the Johns Hopkins Hospital at Baltimore, the Fever and Small-pox Hospitals at Glasgow). In others the separation is nearly as complete, having external open covered passages for intercommunication (the Heidelberg Hospital, the St. Eloi Hospital at Montpellier, and other similar buildings on the Tollet system in France). In a third arrangement the intercommunication is by means of closed corridors and stair cases run up to the first floor, leaving the sick wards as respects their aeration and lighting practically detached (the Menilmontant Hospital in Paris, the Royal Infirmary in Edinburgh, the Western Infirmary in Glasgow, and several Poor-law Infirmaries).

I omit all reference to such institutions as the new Hôtel Dieu in Paris and St. Thomas's Hospital in London, as their cost alone prohibits their being accepted as examples for imitation, even if they were not, as I believe them to be, defective in other respects. Some recent Poor-law institutions, well constructed and otherwise not badly arranged, are made to contain from one to two thousand inmates—an aggregation of sick, in mind and body, universally condemned by the medical authorities of all countries, and therefore not to be quoted for instruction or guidance, for in them the cardinal principles which should regulate all such matters, are sacrificed to administrative convenience and economic reasons. As a rule, in all the above forms of arrangement the administrative buildings are centrally situated; and the out-patients' departments, pharmacies, laundries, kitchens, nurses' and servants' quarters, &c., are grouped in the manner most convenient for the general administration of the whole institution. They will of necessity vary very considerably, according to the uses and size of the hospital, and its connexion or otherwise with a medical school.

It is obvious that if kitchens, laundries, and store rooms have any tendency, as some of them must have, to create an atmosphere likely to be prejudicial to the sick, their complete separation is the only perfect plan of dealing with them. The exact arrangements will be mentioned in connexion with the institutions which I intend to describe, as illustrating the most recent forms of hospital construction which have found acceptance—viz., the Menilmontant Hospital in Paris; the St. Eloi Hospital, about to be erected at Montpellier, in France; the Friedrickshain Hospital at Berlin; the Western Infirmary at Glasgow; the St. Marylebone Infirmary just completed, and an example of a town hospital in New York on the many-storeyed plan, which is a remarkable and successful attempt to adapt old principles of construction to modern sanitary requirements.

The number of beds a hospital should contain must depend so much on its nature and position, coupled with the needs of the population in whose midst it is placed, that no fixed rule can be adopted, such as the Chirurgical Society of Paris hinted at, in its third conclusion. Sanitary conditions, subordinated in a limited degree to administrative and economical convenience, are alone entitled to consideration in the determination of the question.

If economy of administration alone were consulted, or in combination with a decrease in the cost of the ground on which a hospital is placed, the number of beds might practically be unlimited, as it was in that pest-house, the old Hôtel Dieu; and as it is in a lesser degree in some of the older general, and more recent Poor-law, hospitals. The number of stories on the same base and covered by the same roof might in such circumstances be as many as could be occupied with safety, by means of lifts and similar contrivances. But, supposing these conditions to be correct, which they assuredly are not, the limit of the sick who may safely be congregated on a given area is soon reached, and would long since have been determined with absolute accuracy, had proper hospital records been kept. The problem to be solved has been well put by M. Trélat. He said: "It is now an undisputed fact that great collections of men and animals generate a condition of health which is injurious to all exposed to it. Whether these aggregations are temporary or permanent, accidental or periodic, much or little crowded, in a close or an open space, consisting of healthy or sick, the result is always of the same character. The effects of aggregation soon make themselves felt, varying only in their intensity and gravity according to their internal conditions."

Dr. Farr, in the 24th Annual Report of the Registrar-General (p. 230), constructed a table to show the relative mortality of hospitals, based upon the number of their inmates.

Principal General Hospitals in England and Wales, 1861.
(*Special Hospitals excluded from this table.*)

——	Number of Hosps.	Inmates.	Average number of Inmates in each Hospital.	Deaths.	Mortality per ct.
Hosps. containing 300 inmates and upwds.	5	2090	418	2101	100·53
200 and under 300 . .	4	913	239	838	91·78
100 and under 200 . .	22	2898	132	2041	70·43
Under 100	49	2634	54	1240	47·08
Total . . .	80	8535	107	6220	72·88

It is obvious that there are so many sources of fallacy underlying such a statement, so many conditions necessary to be understood are not mentioned, so much difference in the classes of sick admitted to such institutions, and the period over which the inquiry extends is itself so extremely limited, that the table is of no further scientific value than as embodying a rough approximation to what may prove to be a truth on a more extended and strictly scientific examination.

Again, although I at one time accepted and acted upon the doctrine of averages as the surest basis for determining mortality rates in public institutions, I am now disposed to think that a more correct comparative estimate of the healthiness or unhealthiness of hospitals would be obtained by calculating the number of deaths on the actual number treated, and by determining the actual risk to life of a day's residence in each institution. From a statement of this kind recently published by Monsieur Loua in the *Journal de la Société de Statistique* of Paris, it appears that in the hospitals of the whole of France the mortality rate from 1871–76 oscillated between 8·5 and 10·5 per cent. of the actual number treated, and the risk to life of a day's residence in hospital from 0·00237 to 0·00327. In 1876 it was 0 00268, while the daily risk to life of each individual of the entire population was 0·000063, from which it follows that the chances of death in a hospital were forty-two times greater than in the ordinary conditions of life. The sick, however, are only subject to this increased risk during their actual stay in hospital. All such modes of calculation must, however, of necessity be incomplete and fallacious, and no plan will afford even an approximation to accuracy until the whole of the factors involved—age, sex, hereditary tendencies, actual disease, accident or injury, position in life, &c.,—are carefully collected and collated. All this has not yet been done, even in relation to amputations and obstetrics.

A curious experience of the superior value of the pavilion to the block system of hospital construction was acquired during the occupation of Paris by the allied armies in 1814. The sick and wounded soldiers, French and foreign, were treated in the hospitals until no more room could be found for them, when they were placed in the slaughter-houses, vacated for the purpose. In the great hospitals, the Hôtel Dieu, Pitié, and St. Louis, the mortality of wounded French soldiers ranged from 1 in 5, to 1 in 8. In the abattoirs of the Roule, Montmartre, and Menilmontant, the number of deaths among the French varied from 1 in 7 to 1 in 13. Of the foreign soldiers wounded, the deaths in the hospitals were from 1 in 7 to 1 in 13; and in the slaughter-houses, 1 in 10, 1 in 11, and 1 in 19. So struck was the Conseil-Général des Hôpitaux by these results, that they reported, "That the use made of the buildings (abattoirs) for the treatment of the sick, had made it manifest that their distribution was better fitted for their new use, than any of the existing hospitals. That experience had thus proved the correctness of the views of Tenon and Bailly in their reports on the [old] Hôtel Dieu, and the utility of the division of hospitals into separate pavilions—an idea which should be followed in the construction of all hospitals, in which should be united conditions of health and convenience."

It is now beginning to be ascertained that the accumulation of large numbers of sick in hospitals, in addition to being detrimental to themselves, is a source of danger to those dwelling in their immediate vicinity; and that this is especially true of fever, and all other hospitals in great cities or well peopled localities.

Nearly a century since, Sir Wm. Blizard wrote:—"Hospitals are too much crowded with patients. Parade of numbers blinds the judgment, and diverts attention from simple principles, and clearly deduced rules of conduct. The system of hospitals in respect of numbers is founded on a glaring error. By curing, relieving, and dismissing in a shorter time, the sum of patients admitted in a given period, may be even greater from a less than from a larger number of inhabitants. However airy, then, the situation of a hospital, of whatever amplitude and number its wards, still its happy effects will be governed by the proportion of sick persons within its walls. It may be admitted, upon the whole, that the limitation of number in hospitals should be far below what it generally stands." The late Dr. Rumsey, in one of his excellent papers on "Some of the Fallacies of the Statistics of Health and Disease," sums up the general results of the discussion on hospital mortality in the following words:—"(1) That the disease in hospitals and other large institutions, especially the mortality following operations (and universally that after childbirth), are greatly increased by the mere aggregation of patients and, *cœteris paribus*, in proportion to the density of that aggregation, apart from all other circumstances which might affect success or endanger life; (2) that the death-rate calculated, as it should be, on the number of patients, and not on the number of beds, increases with the size of the establishment and the number of its inmates; and (3) that wherever this assemblage of the sick and hurt occurs in the centre of a crowded population, the rate of mortality attains its maximum."

In strict relation to its uses, the number in a hospital may range from the few beds in a cottage hospital, through every stage of increase, to the large hospitals required for town populations, which, in turn, will each fulfil its functions by restriction of its beds to a maximum of 200 or 300; whilst in the vicinity of great cities, where ample ground is procurable at reasonable cost, and the pressure on space is minimised by subdivision, there may be 600 beds, which number should never, in my opinion, be exceeded on any pretext whatever.

As to the number of beds in a ward, however ample and complete the ventilation and healthy the surroundings, they ought never to exceed thirty-two, with annexes containing one, two, or three beds for the separation of cases which need them. Each pavilion in which they are placed should be self-contained, with provision for nurses, baths, water-closets, lavatories, small kitchen, and all other accessories. The minimum of cubic space allowed should be 1200 feet, and of floor space ninety-six square feet for ordinary cases of sickness, these quantities being increased for surgical cases, and all diseases causing exceptional deterioration of the air of a ward. But one bed should be placed in the interspace or piers of windows, and two rows of beds should never be exceeded in a ward, of which the width should vary from twenty-four to thirty feet, the latter in clinical wards only, and all beds should, if possible, be nine feet apart, as wisely obtains in the new Royal Infirmary at Edinburgh.

As to the number of storeys of which the portions of hospital buildings devoted to the sick should consist, I entirely agree with the views of the Chirurgical Society of Paris, and in the manner in which they are now being carried out in Germany, in the United States generally, and by M. Tollet in France. Professor Lister is reported to have said to a distinguished surgeon of New York, in reply to a question as to how far the construction of a hospital would be likely to influence the results of antiseptic surgery—a question suggested by the four storeys of superposed wards at Blackwell Island, which he was then visiting—"It is immaterial how many storeys of wards there may be in a hospital, provided that the details of the antiseptic method are accurately carried out in them all. If these details are faithfully observed, hospitalism can be prevented." That antiseptic surgery has worked marvels in counteracting the evil effects of septic poisons in some classes of surgical cases is undoubted; but, all other conditions being unchanged, I do not understand how it can exert the smallest influence in preventing the evil effects of an atmosphere laden with the exhalations of a large number of sick in other wards, placed in several storeys under the same roof. The cases to which the antiseptic method is strictly applicable are a minority of those admitted to most general hospitals, and the majority, particularly of fevers, lung diseases, &c., demand a purity of atmosphere on their own account, which is difficult to obtain in a multiplication of storeys.

In the United States, in Germany, and in M. Tollet's plans in France, single storeys are preferred for surgical wards on good and sufficient grounds, and two storeys are not exceeded for medical cases.

(*f*) FURNITURE AND FITTINGS OF HOSPITALS.

These should be of the plainest and most simple description, consistent with their fitness for their special uses, and should interfere as little as possible with the free circulation and purity of the air in the wards. Hence all curtains, shelves, cupboards to contain medicines or dressings, and everything else not absolutely necessary for the comfort of the sick, should be prohibited. Foreign observers have remarked upon the cheerless and comfortless look of our hospital wards, but have admitted, after careful examination, that combined with their scrupulous cleanliness, they were, after all, best adapted to secure the successful treatment of disease. The introduction of flowers, pictures, and other amenities to a moderate extent is not only permissible, but beneficial, yet, even in this matter care requires to be taken that they do not diminish the purity of the air in the wards.

To attempt to enumerate the numberless articles of furniture for the sick room now existing, would be a hopeless task. It is sufficient to state generally that all contrivances calculated to secure the most scrupulous purity and cleanliness of place and person, to give ease and comfort to the sick, to arm the surgeon with the instruments best fitted for his work, and to provide the physician with the agencies he needs, should be found in all well regulated hospitals. Those who desire further information on the subject should consult M. Husson's great work, notwithstanding its being now nearly out of date, and should visit the Parkes Museum, in which it is hoped will ultimately be found all the most recent contributions of art and science to this important branch of hospital arrangements.

TYPES OF THE MOST RECENT FORMS OF HOSPITAL CONSTRUCTION AND ARRANGEMENTS.

The great work of M. Husson, the reports of Messrs. Bristowe and Holmes, the treatise of Dr. Oppert, the excellent monograph of Capt. Douglas Galton on the Herbert Hospital, together with many others scattered through our medical and architectural publications, particularly in the *Builder*, under the able direction of Mr. George Godwin, contain detailed and valuable information on the subject of hospital construction and arrangement, up to a late period. In Germany, in Italy, and in the United States of America, there is also a wealth of information for those who seek for further instruction. I must, therefore, content myself with a very few typical examples, bringing the question up to date, to show how far the principles now accepted, are being carried into effect.

Some authorities who have written wisely and well, after long practical acquaintance with hospitals, have doubted whether they were blessings or the reverse to the sick poor from the heavy, and in some cases lamentable, risks to life incurred by those resorting to them. One of them, apparently despairing of their ever being so constructed and managed as to diminish those risks adequately, has even recommended their entire abolition. More than one other, of the greatest eminence amongst authorities, is of opinion that the hospitals of the future should be constructed of temporary materials, so as to be destroyed and renewed every ten years without undue cost, and that no more money should be squandered in building palaces which rapidly become abodes of disease and death. The celebrated Paul Dubois in 1855 declared before the Academy of Medicine in Paris that a woman would incur less danger to life in being confined unaided in the streets, than in being delivered in the Maternity or the Clinique.

The perverse and persistent disregard of the true principles involved, which have been pointed out for more than a century, justified this gloomy view, particularly in Paris, where some of the practices still pursued would be a reproach to the heads of the profession in that city, were they really responsible for it. The recent changes made in some of our metropolitan hospitals, in the vain attempt to bring them up to a higher standard than their original defects will admit of, show that those principles are far from being accepted among ourselves; while the enormous cost, and other objections to the new Hôtel Dieu and St. Thomas's Hospital, make it impossible to refer to them otherwise than as examples to avoid.

It is not so with those which I have selected for illustration, from a very wide field. I have purposely taken such as have not as yet, so far as I know, been made known to the profession in England, while they contain the latest expression of opinion on the question. Some of them are costly, and do not wholly adopt the conclusions of the Chirurgical Society of Paris, but they are all essentially advances on the *status quo ante*, as described by Husson, Holmes, and Bristowe, and Oppert, the authorities best known in England. Two of them carry the conclusions above referred to, to their logical result—the Friedrickshain and St. Eloi hospitals.

(To be continued.)

MEMORANDUM
ON

THE RESULTS OF A TRIAL OF CHIAN TURPENTINE

AS A REPUTED REMEDY FOR CANCER OF THE FEMALE GENITAL ORGANS, MADE DURING SEVERAL MONTHS IN THE YEAR 1880, IN WHITBREAD WARD, MIDDLESEX HOSPITAL.

BY J. W. HULKE, F.R.C.S.,
SURGEON TO THE HOSPITAL.

THE Middlesex Hospital has a specially endowed department, founded in 1792, for the reception of patients suffering from cancer. It is open to all applicants, without governor's letter. Once placed on the Cancer Foundation patients acquire the privilege of remaining in the hospital until, as one of the rules quaintly expresses it, "they are relieved by art or released by death." Another rule requires that a record be kept of each patient so admitted, a trial be made of every reputed remedy which on the face of it does not appear likely to prove hurtful, and the results of such trial be made public. It is therefore obligatory on the surgeons in charge of the cancer wards to examine into the claims of all alleged remedies for cancer brought before the profession; and during my tenure of office I have made trial of several escharotics, of condurango, of Beneke's dietetic method, of arsenic applied topically and also exhibited internally, as recommended by Esmarch; and lastly, of Chian turpentine, introduced to our notice as a new remedy for the treatment of cancer of the female generative organs by Professor John Clay in a very remarkable article published in THE LANCET of March, 1880, vol. i., p. 477.

After narrating four most striking instances of its apparent efficiency Professor Clay added the following remarkable words:—"The Chian turpentine appears to act upon the periphery of the growth with great vigour, causing the speedy disappearance of what is called the cancerous infiltration, and thereby arresting the further development of the tumour. It produces equally efficient results on the whole mass, destroying its vitality, but more slowly. It appears to dissolve all the cancer cells, leaving the vessels to become subsequently atrophied, and the firmer structures to gradually gain a comparatively normal condition." Professor Clay found Chian turpentine "an efficient anodyne, causing an entire cessation of pain in a few days," and, as prescribed by him, it appears to have been no less efficient as a hæmostatic. The idea of its selective action upon the cancer cells appears to have been suggested by the copious, thick, ropy vaginal discharge which, concurrently with wasting of the cancer, he found attended its use. Recommended by a surgeon of position in an article in a leading medical journal, supported by the narrative of cases showing rapid improvement, not to say cure, setting forth such a plausible hypothesis of its *modus medendi*, I could not hestitate to try it.

The result of this trial completely demonstrated to my own mind, and convinced all who watched the practice, that Chian turpentine is thoroughly useless as a remedy for cancer, whether of the female generative organs or of other parts. It was administered during several months to several women suffering from uterine cancer. It was not found to check the progress of the cancer, which in spite of it continued its fatal course. In not one instance did the vaginal discharge assume the thick ropy character mentioned by Professor Clay. As a reputed anodyne it quite failed to lull pain, and during its use opium was found indispensable. With respect to its alleged hæmostatic powers, hæmorrhages occurred as frequently and as copiously in women whilst taking the turpentine as in others to whom it was not given.

The trial was begun with some Chian turpentine which had been long in the hospital drug-store. When this was exhausted other Chian turpentine was obtained of a first-class drug firm. The characteristics of the latter agreed closely with those given by Pereira. I was informed that the genuineness of this turpentine was questioned by Professor Clay, who asked for and received a sample of it, and who very courteously forwarded to the hospital a sample of what he considered the genuine article. Upon comparison it appeared that Professor Clay's pure specimen agreed very closely with the turpentine with which our trial had been begun. A fresh supply of Chian turpentine agreeing with Professor Clay's sample was procured, and the trial was continued with this. The formula first employed was that given by Professor Clay, but later the sulphur was omitted. After trying it in uterine cancer it was given to a woman with an epithelioma of the vulva and of the inner side of the thigh at the junction with the trunk, and to another woman with an epithelioma of the back of the thigh. These cancers being open to ocular inspection appeared very suitable for the recognition of its influence, if any, upon the cancerous tissue. It was also exhibited in cases of scirrhus of the female breast, unbroken, and also ulcerated. In not a single instance could any curative influence be discerned. In conclusion it may be added that mastic, the resinous product of another pistacia, has proved in my hands equally valueless as a remedy for cancer.

The following cases are adduced in support of the above opinion. If it should be objected that these and similar cases were too advanced to admit of cure by the Chian turpentine, the objection would hold if by cure is understood restoration of the cancerously affected parts to relatively normal integrity, but if cure is taken to mean arrested growth and waning of the cancerous tissue, and cicatrisation of the ulcer, the objection falls to the ground in face of the explanation offered by the introducer of the reputed remedy, that it acts in an elective manner, seizing on and destroying the cancer cells, since throughout the duration of the tumour cells of every age, from mere germs beginning life to those advanced in senile decay, are to be found.

CASE 1. *Cancer of uterus, fatal, notwithstanding the internal exhibition of Chian turpentine during about three months.*—A wizen-faced little woman, aged sixty, was taken into Whitbread ward on the 12th March, 1880. The uterus was enlarged and fixed; it was so low as nearly to touch the vulva; the cervix was hard, knotty, and ulcerated.

There was a copious ichorous very fetid discharge. The first indication of uterine disorder—pain—was noticed about two years previously. On April 8th she began to take the Chian turpentine mixture, which she continued until July. The discharge was always copious and stinking, occasionally more puriform and less ichorous. Her suffering was so great as to need the free use of opium. She became feebler and thinner, and died on August 14th.

At the necropsy the uterus was found infiltrated throughout with cancerous growth, and the interior converted into a large sloughy cavity filled with stinking pulpy débris. No secondary cancerous growths were detected in any lymphatic glands or other viscera.

In this case the cancer was still limited to the uterus. In the next case it had infected the lymphatics. In neither was there any evidence suggestive of a retrogression of the local disorder.

Case 2.—A very thin, shrivelled, little blonde, aged fifty-eight, was admitted into Whitbread ward on June 3rd, 1880. Her womb was low, fixed, its cervix tuberously swollen and ulcerated. The anterior wall of the vagina was similarly implicated by infiltration spreading into it from the uterus. She had an extremely fetid ichorous discharge, and she suffered very great pain, which was principally referred to the sacrum. In the preceding November she had begun to occasionally lose blood and to feel pain in the womb. (Menstruation had ceased in her forty-ninth year.) Chian turpentine (without sulphur) was ordered to be taken three times daily, and as the severity of the pain continued in spite of this, she had opium at night to procure sleep. The disease continued unchecked, and death ended her sufferings on August 9th. At the necropsy the uterus and other pelvic viscera were found agglutinated. The uterus itself, and structures immediately about it, were involved in cancerous growth, which on section was found in several places broken down and puriformly softened. The iliac and lumbar lymphatic glands were cancerously enlarged and centrally puriformly deliquescent. Cystitis, suppurative pyelitis, and abscesses in the tissue of the left kidney were noted.

Case 3. *Cancer of uterus, treated with Chian turpentine during about three months.*—A cartridge-bag maker, aged fifty, was admitted into Whitbread ward in April, 1880. Her womb was very low in the pelvis, fixed and enlarged. Its cervix was tuberously swollen and ulcerated, and from this a knotty ulcerating infiltration extended into the vaginal walls. She had considerable pain in the sacrum and thighs, and a thin dirty fetid vaginal discharge. The Chian turpentine mixture was ordered to be taken three times daily. This was continued until July without any obvious influence on the progress of the disorder. The free use of morphia was necessary. Circumstances compelled her removal to a parochial infirmary, where she soon after died. Chian turpentine was taken here about three months.

Case 4. *Cancer of womb treated during several months with Chian turpentine; frequent hæmorrhages.*—A patient, aged forty-nine, was admitted in August, 1879, into Whitbread ward. Her womb was low down in the pelvis, and fixed; its cervix was an ulcerated nodular mass, from which a knotty infiltration spread along the vaginal walls, especially the upper wall. She had a copious fetid ichorous discharge, with occasional large losses of blood; and she suffered much pain in the bottom of the belly and thighs; her bladder was irritable. The disorder progressed, and stillicidium urinæ followed destruction of the vesico-vaginal septum. On April 1st, 1880, she began to take Chian turpentine mixture, and continued this until the end of July. The disease progressed, her sufferings increased, she had frequent hæmorrhages, grew feebler, and at length died on Aug. 4th, the immediate cause of death being hæmorrhage. Her relatives would not sanction an examination of the body.

Case 5. *Cancer of womb; frequent and great hæmorrhages; partial removal with scoop; temporary improvement; Chian turpentine given during several months; fatal termination.*—The patient, aged thirty-three, whose raven black hair heightened the ghastly pallor of her face, was admitted into Whitbread ward on March 25th, 1880. Since the preceding November she had had large and frequent losses of blood from the womb. The cervix uteri was a large cauliflower-like mass which bled freely on the slightest touch. The body of the uterus was enlarged, but still movable. She said the hæmorrhages had begun about ten months after the birth of her last and seventh child two years before. As she was plainly dying of hæmorrhage, and the removal of the cauliflower-like mass offered a prospect of checking the loss, it was removed with a Volckman's scoop, with which also the body of the uterus was hollowed out until it was reduced to a thin shell of firm tissue. This large cavity thus made was filled with a plug of absorbent cotton-wool, dusted over with powdered persulphate of iron, with the double object of checking bleeding and causing a superficial eschar. When the latter was thrown off the surface of the wound appeared healthy, and cicatrisation made such quick progress that at the end of a month a small, firm, puckered bluntly conical knob was all that could be felt of the womb. Before long, however, ulceration recurred, and she again began to lose blood. On April 1st she was placed on the Chian turpentine mixture, and she took this with occasional interruptions of a few days until the end of July. In spite of this the disorder progressed and terminated fatally. No examination of the body was permitted.

Case 6. *Cancer of the vulva and thigh; extensive secondary infection.*—Here, the cancer being in part of its extent open to ocular inspection, the case offered an unusually favourable opportunity for studying the influence, if any, of the Chian turpentine on the disorder. A thin, tall, white-haired monthly nurse, aged seventy, was admitted into Whitbread ward on April 10th, 1880. Her left greater labium, the vagina to a height which precluded excision, and the neighbouring parts of the inner surface of the thigh were involved in an ulcerated epithelioma. She had first become aware of the disorder about two years previously, and through false shame had only lately sought assistance for it. Chian turpentine was ordered, and she continued to take it until late in the autumn. The disease progressed, and she lingered on till Feb. 18th, 1881, extensive implication of the lymphatic glands having occurred.

At the necropsy, in addition to the cancerous growth and ulceration in the region already mentioned, the left groin was filled with a mass of cancerous lymph-glands centrally softened, distending the skin, which had ulcerated. The femoral vein was plugged. The left iliac and lumbar and the right inguinal glands were cancerously swollen, and there was a small cancerous knot upon the surface of the liver.

Old Burlington-street, W.

ETIOLOGY AND CLINICAL BEARINGS OF THE GERM THEORY OF DISEASE.

By DR. GEORGE HARLEY, F.R.S.

The Editor calls attention to the following

Note by the Author.—"Reformed speling: This paper is printed without encumbering its words with redundant, and consequently useles, duplicated consonants."

It must be understood that The Lancet does not adopt the method, but simply complies with the request of Dr. Harley.

CHAPTER III.

Clasification of the Germs which produce Human Diseases.

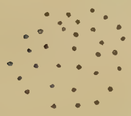
As I shal almost imediately take ocasion to aduce a few facts which tend to the belief that while some of the presently recognised specific species of human disease-germs may in the end turn out to be either mere varieties, or even simply diferent gradational stages in the developmental career of one and the same species of organism, as wel as to show that it is almost certain that other, as yet unknown, species of disease germs wil shortly be discovered, I do not desire it for one moment to be suposed that I subjoin the folowing clasification of human disease-germs as anything more than a tentative one. But I do so, nevertheles, without reluctance, wel knowing that even an imperfect clasification of things always materialy asists in advancing the progres of scientific truth, and I leave it for my readers to value or to condemn it, according to their knowledge and discretion, feeling sure that it wil at least prove useful to both observers and readers until a more advanced stage of our knowledge furnishes us with a beter.

Table of Human Disease-Germs.

(A) Brownian granules: Minute, opaque, solid, moving spherical bodies of the size of 1·50,000th of an inch in diameter, existing normaly in bucal mucous cels, and white blood-corpuscles, and abnormaly in living blood-serum, milk, melanotic mater, and urine, as wel as in al decomposing animal fluids.

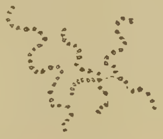
(B) Vibriones: Strings, often branched, of equaly minute particles, in constant motion. Not existing in normal fluids, but only and always in decomposing animal fluids—in or out of the body—such as blood, milk, serum, and urine, as wel as in abnormal living contagious liquids—gonorhœal, syphilitic, ophthalmic, and smal-pox pus.

FIG. 9.



Brownian granules.

FIG. 10.

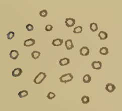


Vibriones.

(C) Micrococi: Homogeneous, spherical pelucent bodies, larger than Brownian granules, usualy floating free, either singly, in groups, or like vibriones in bead-strings. Found under pathological conditions, such as in sheep-pox and smal-pox pus, as wel as in the living blood itself in smal-pox and putrid fevers, and in pus of supurating wounds. In diphtheritic deposits numbers of micrococci are found (Oertel, Klebs, &c.) as wel as in the lymphatics and lymphatic glands of diphtheria. Nepveu found micrococi in the blood (*Jahresbericht*, 1872, i., p. 254), and Orth in the bulæ of erysipelas (*Arch. Exp. Path. u. Pharm.*, i., p. 81).

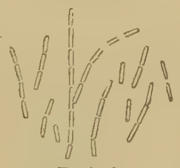
(D) Bacteria: Sausage-shaped germs, sometimes ocuring singly, frequently in longer or shorter strings, like strings of Cambridge sausages—sometimes jointed. Met with in the living fluids under pathological conditions, and among al decomposing animal maters (in the blood of chicken-cholera and catle-plague, Pasteur says). Birch-Hirschfeld thinks the unhealthines of a wound is in proportion to the number of bacteria it contains. He says that he also found them in the blood of pyæmia, but as he speaks of them as being spherical (= microsporon septicum), his remarks have reference to ordinary micrococi.

FIG. 11.



Micrococi.

FIG. 12.

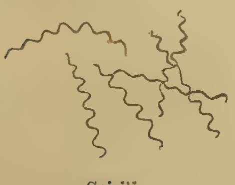


Bacteria.

(E) Spirili: The name of spirili has been given to a species of long hair-like germs of not more than 1-3000th of a line in diameter, of a corkscrew-like form. Like vibriones, they are generaly found in active movement, and have been detected as special organisms in the blood in cases of "woolsorters' disease" and relapsing fever.

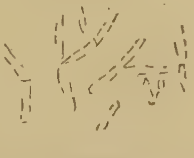
(F) Bacili: Baton or short rod-like germs, of which there are three distinct pathological varieties, although they are exactly the same in apearance, sometimes ocuring single, sometimes double, sometimes multiple, sometimes branched. The varieties are respectively named bacilus malaria, bacilis anthracis, and bacilus septicæmia.

FIG. 13.



Spirili.

FIG. 14.



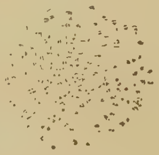
Bacili.

N.B.—When germs are grouped together, and closely-packed into bundles, they are caled a zooglœa.

Lastly, though not least, I ad to them—

(G) Germ-spawn, of al kinds, a fine granular mater, frequently spoken of as clouds of granular débris, which, although infinitesimaly minute, has nevertheles specific pathological characters, and is always visible in al fluids containing mature germs, in which the germs are seen floating in it as if in a cloudy sea when examined under a twelfth of an inch lens. It is even generaly to be readily seen with a good eighth and a proper ilumination. It is met with wherever mature germs exist, and is easily found in decomposing liquids, such as blood, urine, and milk, as wel as in softening tubercle, cancer, &c. Although the various kinds of spawn are entirely indistinguishable from each other by the microscope, they are nevertheles organicaly distinct in their nature, for when injected into healthy animals, they each give results acording to their special kind—smal-pox causing smal-pox, tubercular causing tubercle, putrid blood causing fever, &c. &c. It canot surprise us that al germ-spawn is alike in apearance when we know that the formative cels in almost every bird's eg, fish roe, and animal's ovum, are alike, and yet that each eg, roe, and ovum develops acording to physiological law into a diferent species of mature animal.

FIG. 15.



Germ-spawn.

As is seen in the above table of germs, I make a distinction between Brownian granules and micrococi, vibriones, and bacteria, which many observers imagine are only diferent stages of development of the same organisms. Therefore, lest my opinion should mislead, I must here throw out a word of warning, especialy to the young observer of microscopic organisms, and that is, never hastily to jump to the conclusion that he has discovered a new species when he encounters a family of germs difering either in color, size, or form from those that have been already described, for just as the black and the white turkey, the tiny Shetland pony and the gigantic dray-horse, the tailes [? tail-less, ED. L.] Manx cat, and the long-tailed Londoner, the nut-sized wild turnip, and the enormous field swede, the standard and the drooping ash, in spite of their respective disimilarities, are each in its turn mere varieties of the same species, the results of feeding and breeding; so in many instances the variations in the size, color, and form of microscopic organisms are but the result of a changed habitat and an altered diet. Or, perhaps the variety in size, form, and color may be the mere normal result of diferent stages in their progresive development, just as we notice strange mutations ocur during the life history of the comon parasitical tapeworm, which apears as a measle at one time, a globular hydatid cystic at another, and a long segmented tapeworm at a third. In fact, I am not at al sure that some observers do not think that, even in spite of vibriones (chain-like granules), micrococi (spheroidal bodies), bacteria (sausage-shaped elements), and spirili (corkscrew-like filaments), not only difering in form, but in pathological properties, they may perhaps in the end turn out, like the hydatid and the tapeworm, to be mere gradational morphological forms of development of the same organism, and their difering pathological results be found to be entirely due to the situation they grow in and the food they eat. In a paper comunicated by Dr. George Thin to the Royal Society (March 3rd, 1881), it is said that in cultivating bacteria artificialy he had seen the circular spore or cocus elongate into a rod, then a long rod, and finaly change into a tube, and become filed with new spores or coci. Moreover, he noticed that they sometimes changed their color by taking into their interior the pigment in which they grew. Koch had already (in 1876) made known the fact that vibriones, and chains of micrococi, break up into separate spheroidal germs.

However, it is stil an undeniable fact that there do actualy exist a variety of kinds of diseased germs difering not only morphologicaly, but also stil more, as shal be shown presently, in the pathological efects they produce; equal care is necesary to prevent the young observer from shipwrecking his bark on either shore of the somewhat intricate germ chanel. For be it noted that we never by any chance hear of a typhoid infection germ under any circumstances inducing scarlet fever, or a scarlet fever infection germ in any case whatever leading to an atack of smal-pox; while on the other hand, although we may have measles mixed up with scarlet fever, and scarlet fever with diphtheria, it does not, I think, in any way prove that it was one species of germ that gave origin to the two kinds of diseases, but merely that the patients so afected have at one and the same time become inoculated with two entirely diferent forms of disease germ.

Nay more, I shal presently aduce evidence to show how diferent germs, though introduced into the human body at the same moment and in the same fluid—as hapens when syphilis or glanders is introduced along with vacination lymph—wil hatch, develop, multiply, and run through their whole pathological career, not only quite independently of each other, but without even so much as interfering in the slightest degree with either the course or with the efects of each other.

As I have a good deal more to say on this subject I shal leave it for the present.

Lest, notwithstanding al this, some of my readers may stil think that in the case of such exceedingly minute organisms, many of which are almost morphologicaly identical, it is drawing too fine lines of distinction to give them diferent names, I may as wel inform them that this has not been done on insuficient grounds, as they wil be able to judge for themselves when I tel them that there is quite as great a diference between the constitutions even of two kinds of bacili—notwithstanding their aparent morphological identity—as between a tiger and a zebra, two animals closely resembling each other not only in size and in form, but in having a tail, four legs, as wel as in having striped skins, yet each has, nevertheles, an entirely diferent constitution; for while the one can only subsist on vegetable, the other can only exist on animal, food. Quite as great a diference in constitution is found in two kinds of bacili. For while the bacilus septicæmia flourishes luxuriantly in an infusion of hay, it perishes at once in the serum of the blood of a living animal; while the bacilus anthracis refuses to develop in hay infusion, yet grows and multiplies apace in living blood. What is the food of one germ thus apears to be the poison of the other; yet, strange to say, notwithstanding this aparent disimilarity in constitution, both the septicæmic and anthracic varieties of bacili grow and thrive in a dilute watery extract of muscle. So it must be admited that even as regards their food they poses [? possess, Ed. L.], at least, some points of afinity. In a paper in the *British Medical Journal* of 1880, Lister says that Buchner having observed that spores never formed by the bacilus growing in defibrinated blood, it ocured to him that, perhaps, if it were transfered to extract of meat, and induced to form spores there, the modified organism might yet grow in the blood of a living animal. The carying out of this idea was crowned with suxes [? success, Ed. L.], and, both in the mouse and in the rabit, Buchner suxeeded in producing disease by injecting various diferent quantities containing the organism into diferent animals. When large quantities were introduced the animals died rapidly from the merely chemical toxic efects of the injected liquid; but, in some instances, after the period for these primary efects had pased away, a fatal disease supervened, atended, as in anthrax, with great sweling of the spleen, the blood of which was found peopled, as in that afection, with newly-formed bacili, and the constituents of their spleens afected in this way were found to comunicate anthrax to healthy animals, just like those of animals which had died of ordinary splenic fever.[1] The bacilus malaria is said by Klebs and Tommasi-Crudeli (1879) to infest the soil in the malarial districts round Rome, and when introduced into the bodies of healthy rabits to induce in them an intermitent fever, while Marchiafava has suplemented these observations by saying that in cases of fatal malarial fevers he has found bacili in the blood. There is yet another kind of (an unamed) bacilus, which has not only been met with in the false membrane of the fauces, but in the kidneys and urine in cases of diphtheria.

Nearly al pathologists now admit that although the bacilus anthracis is undoubtedly the cause of woolsorters' disease and splenic fever, and the bacilus septicæmia that of metastatic absceses, the one form of germ has no efect whatever in producing the other's form of disease. So I think that none of my readers wil longer hesitate to acknowledge that although the diferent bacili have identical microscopic characters, they are esentialy diferently constituted forms of disease germs, and consequently have a right to be distinguished by diferent names.

Again, while bacteria and micrococi closely resemble, except in size, Brownian granules and vibriones, the later are generaly to be found in active movement, the former are not. Brownian granules ocur in healthy tisues, micrococi never do. While bacteria are abundantly met with in contagious pus, micrococi are only comon in what is caled laudable pus, such as is obtained from supurating wounds and acute absceses.

It must not be suposed that visible germs must be necesarily found in al purulent, and other kinds of contagious fluids. For, on the contrary, in vacine lymph, for example, it oftentimes hapens that none are to be detected by the microscope. In such contagious fluids I believe that the germ-spawn is alone present, and that unles germ-spawn were actualy present the comunication of disease by the lymph would be entirely imposible. Even in the pus of thirteen typical chronic—so caled cold—absceses, whose duration could be measured by months, and which arose from diseased bones, scrofulous glands, &c., Dr. Ogston says that he could find no germ organisms, although in pus found in other kinds of absceses, he detected them readily (*Brit. Med. Jour.*, 12th March, 1881). Although every medical man knows, or at least ought to know, that the most benign and healthy physiological materials may become malignantly pathological, from either ocupying an abnormal situation, or even a normal situation in an abnormal quantity, it may be as wel for me here, in conexion with the germ theory, to ad a fact not as yet suficiently recognised—namely, that the law that healthy mater when out of place is a morbid product must never be lost sight of in studying by experiments on animals the pathological action of germs. Thus, for example, although Brownian granules are not only harmles, but actualy normal constituents of the bucal secretions, they are not only abnormal but virulent pathological products when placed in the subcutaneous celular tisue. As before said, Brownian granules, in active living movement, are to be met with both in the normal mucus cels of the saliva and the white corpuscles of the blood[2] in perfectly healthy individuals. This was first demonstrated to me six-and-twenty years ago by Profesor Bischoff, one day when I was caling upon him in Giessen, puting some of the saliva from his own mouth under the microscope, and showing me the Brownian particles in active movement in the mucus cels. Strange to say, we failed, on the same ocasion, to find any in active movement in the mucus cels from my own saliva. (N.B. The movement is only visible under a high power, and the higher it is the more distinct it is.) Brownian particles in active movement are not only met with in putrid fluids, but in abnormal quantity in living fluids in disease. I particularly observed this in a case of pyæmia, where there was present an imense exces of white corpuscles in the circulation. I say white corpuscles; but I might have caled them mucus corpuscles or even pus cels, for in so far as their apearance was concerned they had as much right to be caled the one as the other. For had I seen the same cels in saliva I would have caled them mucus corpuscles. While had I seen them in fluid taken from an absces I would unhesitatingly have named them pus cels, and it is only because I found them in blood that I have caled them white corpuscles. Anyhow, they contained an unusual quantity of moving Brownian granules.

Hence we see it is not always the mere presence of germs, but the *quantity* of the germs in the situation which gives to them their pathological significance. The presence of Brownian granules and vibriones in living fluids and tisues, again, is always to be regarded as evidence of morbid action. For, although always to be met with in normal animal fluids—blood, milk, urine, &c.—as the result of decomposition out of the body, they are never met with in any quantity in the living tisues or fluids except as the result of disease. Brownian granules, for example, swarm in melanotic cancerous tisues. While, again, in cases of pyæmia they are abundantly met with in the living circulating blood. Saliva contains a ferment which turns starch into sugar, and most probably this ferment is the viable, active Brownian granules it contains.

The fact above aluded to, that healthy mater out of place is an abnormal pathological product, has recently received remarkable confirmation by the experiments of Vulpian, who, in a note to the French Academy, says that he injected under the skin of rabits saliva colected at the very moment of the experiment from perfectly healthy individuals; and this injection kiled the rabits so inoculated in forty-eight hours. The blood of these rabits was found filed with microscopic organisms, among which was found a special organism, discovered by M. Pasteur in the course of his experiments with inoculation of the saliva of a child who had died of rabies. One drop of this blood, diluted in ten grames of distiled water, and injected under the skin of other rabits, also brought on the death of these animals, the blood of which was similarly filed with microscopic organisms; while other rabits, not in the same way predisposed to the pathological efects of the saliva germs, when operated on under identical conditions with the same saliva, experienced no il efects from their inoculation.

---

[1] See Ueber die experimentele Erzeugung des Milzbrandcontagiums aus den Heupilzen, von Haus Buchner. München, 1880.

[2] Those Brownian granules met with in blood corpuscles have received the name of hæmococi by some, microzymes by others; but I prefer to retain the original name of their first discoverer.

Now, although not a single word is here said about Brownian granules, as these are the only living micro-organisms normaly existing, as I have just shown, in human saliva, I have no doubt it was owing to their breeding and multiplying abnormaly in the subcutaneous celular tisue of the rabits that induced their death. The probability of this being the corect theory wil become more aparent as we proceed with the consideration of the life history of microscopic germs.

There are three forms of disease in which the saliva asumes most virulent characters—glanders, rabies, and syphilis; each of which is due to the development in it of an entirely diferent specific germ organism. Numbers of other very comon afections might be pointed out as being due to specific forms of disease germs; as, for example, an influenza cold, which is wel known to be such an infectious disease that even if a cat begins to sneeze from it the chances are that it wil soon spread itself to every human member of the household. It is said by some Frenchmen to be due to the fungoid mould caled the Coprinus domesticus; while the comon thrush in the mouths of children—the "muguet" of the French—is thought to be due to the Botrytis basiana, the same kind of fungus which produces the potato blight and the vine disease, as wel as the epidemic cutaneous diseases of salmon and silkworms.

It must not be for one moment suposed that we are already acquainted with al the diferent species of disease germs, and that al morphological forms subsequently to be met with are to be regarded as mere varieties of known forms; for, on the contrary, I opine that many more "perfectly distinct species" may yet be discovered. For example, the milk from a dairy belonging to a reformatory school of over 150 boys, near Aberdeen, in the begining of April, 1881, apears sudenly to have become impregnated with poisonous germs, for within a few days ninety families who received their milk from the reformatory where the cows were kept were afected with what apeared to be a new disease. Over three hundred persons were atacked, and only twenty of the families suplied with milk escaped. No case of the disease was found in any family that did not receive its milk-suply from the reformatory dairy. The persons were atacked with severe rigors, which might last several hours, or even for a day; these were folowed by marked febrile symptoms. The tonsils were slightly enlarged, but there was no false membrane; and a marked feature was the sweling of the lymphatic glands of the neck and those imediately above the clavicle. The prostration was extreme. The febrile symptoms pased of in a few days; but in a great many cases there was a suden relapse, and the relapse was often more severe than the primary atack. In a few cases the atack was slight, but it proved fatal in three cases where the patients were old and trail, and unable to recover from the prostration. A peculiarity was that the oficials of the reformatory were afected, while the boys almost entirely escaped. The boys got skimed milk while the oficials were suplied with sweet milk. The suply of milk was ordered to be stoped, and the spread of the disease stoped as sudenly as it began. Comisioners investigated the mater, and the evidence clearly showed that the water-suply to the dairy-farm was not satisfactory, for al the water for the cows came from a large and practicaly uncovered cistern, which was placed in the byre where thirty cows were kept. The water, on being analysed, was shown to be bad, but stil that was not suficient to show how the disease originated. It was not shown that this water was aded to the milk, though some of the milk-pans may have been washed with it. The comisioners—Mr. Andrew Rutherford, advocate, and Dr. H. D. Littlejohn of Edinburgh—say on the authority of Profesor Ewart, who examined the milk microscopicaly, that it contained micrococi and bacteria organisms, which seemed in some respects to be of a character entirely new to science. But, as far as the evidence went, they declined to say how these organisms came into the milk. A post-mortem examination was made of the body of one person who died from the disease; but no organisms were found either in the blood or in any of the tisues. Nor were any organisms found in the blood of patients sufering from the disease.

After what was said regarding the variations in form of microscopical germ organisms, the above idea of the species found by Profesor Ewart being "entirely new to science" requires coroboration before it can be implicitly axepted. The only colateral suport it has is in the fact that the pathological symptoms, the organisms produced in the persons they afected, were in themselves of such a most unusual and anomalous kind as leads to the belief that in al probability their exciting cause was equaly uncomon. Further and more complete investigation wil alone reveal the truth.

The next chapter wil be on the Incubation of Disease, and the causes of long intervals of quiescence ocuring between the cesation of one and the outburst of another epidemic of the same kind in the same district.

ON SOME

RARE FORMS OF DISEASE, ACCOMPANIED BY LESIONS OF TROPHIC NERVES OR TROPHIC CENTRES, AND ILLUSTRATIVE OF TROPHIC CHANGES.

BY WILLIAM ALEXANDER, M.D., F.R.C.S.

(Concluded from p. 987.)

MY next two cases illustrate trophic changes produced by lesions of the cortical substance of the cerebral convolutions.

CASE 3. *Sloughing of nose and part of face, the result of a cortical lesion of the brain; death; post-mortem.*—J. O——, aged forty-eight, a labourer, admitted June 15th, 1878, with sloughing of the right cheek and right side of the nose, the result of an attack of erysipelas which began a month ago. As the sloughing process was proceeding rapidly, the diseased tissues were removed completely by the thermo-cautery. This apparently stopped the unhealthy action, granulations soon covered the right cheek, but the bones of the nose were bare, and the nostrils perforated just below the nasal bones from the complete destruction of the upper lateral cartilages. The margins of the nostrils were intact. On August 26th, 1878, a plastic operation was to have been performed, but the wound was found to be slightly phagedænic and the patient feverish, in consequence of which the operation was postponed. A fortnight afterwards a new nose was made from the skin of the forehead; the flap united well, and a small ulcer on the cheek was almost healed by the end of September. In the beginning of October sloughing recommenced beneath and to the right of the flap, which became detached by the destruction and liquefaction of the subjacent and adjacent tissues. The nasal mucous membrane poured forth a profuse and most fetid discharge, and the patient sank into a state of semi-coma, with low muttering delirium and typhoid symptoms. The fetor was so great that removal to a small separate ward became necessary for the comfort and safety of the other patients. In a week, and after being moribund for three days, the symptoms of death abated, and by Nov. 20th the ravages produced by the sloughing were being repaired. The flap was still healthy, though shrunken, and was becoming attached to the neighbouring granulations. On December 5th the patient passed an uncomfortable night, with pains and cramps in the stomach and bowels, and next morning the wound was sloughing. In a few days all was again going on well. On the night of January 16th, 1879, the key to the mystery was discovered. The nurse on going into the ward noticed the patient to be shaking, and on approaching nearer she found him "working" in a fit. On awaking he complained of pain and cramps in the stomach. Next morning, on being closely questioned in regard to the fit, he declared that he had had fits for the past thirteen years, ever since he received a blow upon the head. On looking at the spot indicated, a small depression could be felt on the left parietal bone, rather posterior to its centre. He never recovered from the effects of the fit on Jan. 16th, but gradually sank into a state of coma and low delirium, and died on March 4th.

A post-mortem examination showed that the depressed fracture pressed internally by a sharp protuberance upon the middle of the ascending parietal convolution, and slightly on the convolution in front and behind. An area about the size of a shilling, and apparently not deeper than the thickness of that coin, was greyish and softened. Strange to say, a small patch of grey softening was found on the opposite side of the brain. The remainder of the brain was healthy. The nasal mucous membrane was thick, ulcerated, and sloughy, and the nasal bones carious. All the organs of the body were examined, but do not call for further remark.

Remarks.—It may be reasonably assumed that the original disease for which the patient was admitted to hospital was sloughing of the side of the nose and cheek, excited by a trophic disturbance, emanating from a cortical lesion of the brain. Whether convulsions always accompanied the explosion that ended in such severe trophic mischief it would be impossible to say. Pains and cramps followed the fit, and were always complained of just before the destruction of tissue began. The area of sloughing corresponded with the area of distribution of the superior division of the fifth nerve on the face and in the nose, and on each occasion the destructive action was limited to the same spot. Motion and sensation were unaffected after the removal of the sloughs, and healing always proceeded rapidly, so that the destructive action was temporary in duration and the nervous action of the affected part perfectly normal in the intervals. From a surgical point of view, the case is extremely interesting. The history was unknown till the knowledge of it was useless, and yet, had it been known before, although the connexion between the depressed fracture and the sloughing might have been strongly suspected, the suspicion would scarcely have warranted operation. In a similar case a favourable result might, with confidence, be expected from the use of the trephine.

Avoiding all bearings of the case upon cerebral location and trophic centres, I shall now narrate a case where the diseased action was less violent and more continuous, and where decided relief resulted from operative interference.

CASE 4. *Tertiary syphilis with necrosis of skull and intractable ulceration of the left ala nasi and left half of upper lip; ulceration; cured by removal of part of the diseased calvaria.*—Ellen S——, a prostitute, aged thirty-six years, was admitted to the hospital November 8th, 1876. Has had one child, which was killed by an omnibus running over it. Has suffered from venereal disease for two years. At the time of admission necrosis of the left lower jaw of the upper central region of the frontal bone and of the hard palate was taking place. Besides, she was suffering at the same time from ulceration of the tonsils, and raised, circular, copper-coloured spots could be seen on both hands and arms. On January 15th, 1877, a sequestrum was removed from the diseased jaw. On February 12th another sequestrum had come away from the hard palate, leaving an oval-shaped hole about its centre, and on March 12th a piece of the outer table of the skull came away. In the frontal region, the necrotic and reproductive changes now came to a standstill, and for months no alteration was apparent in the worm-eaten patch on the forehead. During this time the left upper lip and the inner and upper part of the left thigh were the seat of deep ulcerations. These subsided by February, 1878, when a small, painful, flesh-coloured tumour formed in the urethra, causing much depression and mental distress. This was removed on May 28th, but the resulting ulcer healed slowly and was ultimately cured by the retention of a zinc-alum point in the urethra for some hours daily. She had now a rest from active disease for a few weeks, but in 1879 the lip and calvaria became again the seat of active disease. In the former ulceration of the soft parts only, and in the latter the scalp and calvaria were both affected over an area that included the vertical plate of the frontal bone, and the anterior two-thirds of both parietals. In December the frontal sequestrum and part of the parietal were forcibly elevated from the neighbouring parts, and were found to consist of both tables. Beneath it was a quantity of pus lying upon a thick membrane which moved with the pulsations of the brain. It should have been mentioned that the ulcerating process in the lip was accompanied by much pain. Next day this pain had completely disappeared, the "angry" appearance of the part was markedly less so, and in a few days the ulcer was completely cicatrised. Afterwards the greater part of the parietal sequestrum was removed with the exception of a few small pieces which came away some time after in the dressings.

This case is interesting from a syphilitic point of view, but its narration in this connexion is intended to illustrate a fact pointed out several years ago by Mr. Lane, that ulcerations of certain parts of the face, intractable to treatment, heal rapidly when necrosed bone is removed from the calvaria. He recommended the surgeon to assist nature in such cases in opposition to his contemporaries, who thought it better to allow nature to take her own course.

No doubt in this case the brain beneath was irritated on the right side (and probably nearly in the same region as in Case 3) by pressure of the pus beneath the bone, and instead of lesion of motion or sensation the result was a painful ulceration. Where such a connexion is suspected operation is called for, but if the necrotic processes of the calvaria are proceeding innocuously the operation is not indicated, and cannot, except towards the last, hasten recovery.

Liverpool.

WOUND OF ABDOMEN, WITH PERFORATION AND PROTRUSION OF INTESTINE; RECOVERY.

By HENRY WILLSON, M.R.C.S.,
SURGEON TO THE ROYAL SOUTH LONDON DISPENSARY.

ON December 14th, soon after midnight, I was summoned to E. D——, aged twenty-two, who was stated to have been stabbed. I found her supported in a chair in a semi-collapsed condition, with frequent retching. Examination revealed a clean incised wound, one inch and a half long, in the left hypogastric region, extending upwards and outwards in a line parallel to the fibres of the external oblique muscle. From the wound about two feet of small intestine were protruded, the bowel being scratched in one part and divided through half its circumference in another, the rent almost exactly corresponding in size with the external wound and with the incisions through the clothes, which were afterwards examined. The wound of the intestine was on the side distant from the mesentery and very little bleeding took place from it, but the contents of the bowel, of a semi-fæcal character, escaped slightly every time the patient moved. As she was cold and almost pulseless, I decided to do what I could for her without the risk of removal, so, having covered the protruded intestine with warm wet cloths, I left her in charge of my assistant and fetched my friend, Dr. Cyril Jones, who, fortunately, was provided with some carbolised catgut, with which the wound in the intestine was united by a continuous suture. It was found impossible to reduce the bowel till the external wound was enlarged, so chloroform was administered and the abdominal wall slit up for about three-fourths of an inch, using the finger as a director. The intestine, by this time highly congested and cold, was returned with some difficulty and with grave doubts as to the patient's survival. The edges of the external wound were brought together with silk, and a dressing of lint with carbolic oil applied. Small doses of brandy-and-water were administered with marked benefit. As she presented all the appearances of impending collapse, her depositions were taken by the inspector of police. She soon felt great pain in the seat of the injury and in the umbilical region, vomiting was persistent, tongue dry and thirst intense, pulse 120, very small. A grain of morphia was placed in the rectum, and teaspoonfuls of milk and soda-water given frequently, with small pieces of ice to suck. At 4 A.M., I left her, scarcely expecting to see her alive again. During the day she continued with all the symptoms of peritonitis: knees drawn up, abdomen tense and painful; pulse 130, temperature 102°; vomiting continuing, but not so severe.

Dec. 15th.—Condition much the same; vomiting not so frequent; only teaspoonfuls of milk and soda-water retained. After some hæmorrhage from the vagina, an abortion of about three months was expelled, the continuous flow of dark blood causing a suspicion that the uterus had been injured. Wound looking healthy.

Dec. 17th to 19th.—Peritonitis continuing; pulse 130; temperature varying between 102° and 104°. Wound began to gape, and edges very inflamed; suppuration copious. Diet the same, in very small quantities. Morphia suppositories used freely, and nourishing injections given.

From Dec. 19th to the end of the month she continued in a varying condition. The wound gaped from the abdominal tension, and the sutures all gave way. It was impossible to replace them, because of the adhesions that had formed with the parts underneath, appearing to be partly intestine and partly omentum. She frequently vomited, and many of the injections returned. She became very emaciated, and exhaustion constantly threatened. Suppuration was severe, the matter appearing to well up from the peritoneal cavity, and several superficial abscesses formed, the most severe one being over the pubes. These were poulticed and the wound dressed with carbolic lotion and marine tow. The uterine hæmorrhage was occasionally severe. No blood escaped from the rectum with the exception of one small hardened clot, which came away with an injection. The bowels first acted on the eleventh day. The first motions were hard and natural; they afterwards became loose, and resembled thick paint. During the last days of the month she swallowed and retained eggs and milk, and the motions became more copious. She also took teaspoonful doses of mixtures containing liquor opii and home-made chlorodyne.

Early in January, the suppuration continuing severe, and the wound still gaping, I feared that protrusion of bowel might again take place, and recognising the necessity of prompt action in case of such an accident, my friend Mr. Golding-Bird kindly found her a bed in Guy's Hospital; but when all arrangements had been made, she refused to be moved, so she continued under the kindly, but decidedly amateur, nursing of her mother.

From Jan. 8th to Jan. 15th large pieces of curdy matter, the shape of fæces, escaped from the wound, with increased suppuration, but she now took nourishment freely, and her pulse and temperature had become almost normal, the bowels acting about three times a week, the motions being mostly natural.

Jan. 16th.—I was able for the first time to pronounce her out of immediate danger.

17th.—I found her, without my permission, sitting up in bed eating stewed rabbit; wound smaller and granulating; discharge less; another abscess forming over pubes.

18th to 25th.—Patient improving; eats fairly.

From Feb. 1st she gradually improved, and is now in perfect health, suffering no inconvenience or pain in the bowels. She wears an abdominal belt, and is enjoined to be careful not to over-exert herself.

It is noteworthy that the patient should have recovered in the face of so many dangers—viz., the serious injury and peritonitis, the abortion and hæmorrhage, the hurried operation performed by the light of guttering tallow candles, held in our fingers, in a dirty, ill-ventilated room, without antiseptic precautions, or even proper cleanliness, and no skilled nurse to carry out my directions then or afterwards. The morphia suppositories, employed largely at first, were most useful in quieting the nervous system, and keeping the bowels at rest. Much of the good result was owing to the valued assistance of Dr. Jones, and the unremitting care of my assistant, Mr. J. V. Young.

Great Charlotte-street, S.E.

ON THE

EMPLOYMENT OF ENEMATA INSTEAD OF PURGATIVES FOR THE RELIEF OF CONSTIPATION IN ENTERIC FEVER.

BY JAMES W. ALLAN, M.B.,
SUPERINTENDENT AND PHYSICIAN TO THE CITY OF GLASGOW FEVER HOSPITAL, BELVIDERE.

IN the following brief note I shall call attention (1) to the objections against the use of purgatives in enteric fever, and (2) to the advantages of enemata.

OBJECTIONS TO PURGATIVES.

OBJECTION 1. *Purgatives may irritate the stomach.*—In enteric fever, as in most febrile disorders, the stomach is easily irritated and upset. It is therefore a matter of great consequence to spare the stomach any needless disturbance, so as to preserve it in the best possible condition for the performance of its function—namely, digestion. Stomachal digestion is of special importance in enteric fever, where we wish to spare the intestines as much work as possible. Again, it must be borne in mind that even mild purgatives, such as castor oil, may induce nausea and vomiting, and the latter, as we are aware, may be attended with the possible danger of intestinal perforation in the advanced stages of the disease.

OBJECTION 2. *Danger of inducing troublesome and exhausting diarrhœa.*—I am satisfied that the indiscreet use of purgatives in enteric fever may give rise to severe and injurious diarrhœa, which may rapidly exhaust the patient, partly by the loss of fluid, and partly by the fatigue of frequently going to stool. It would appear that in some cases of enteric fever a purgative may give rise to sudden and startling prostration.

OBJECTION 3. *Danger of inducing hæmorrhage.* — It cannot be overlooked that if we give purgatives which will throw the ulcerated small intestine into violent action, by so doing we run considerable risk of starting intestinal hæmorrhage. When we call to mind the condition of Peyer's patches in the advanced stages of the disease, it will be apparent that this danger is not a chimerical one.

OBJECTION 4. *Danger of causing intestinal perforation.*—The reality of this danger will also become evident to anyone who reflects on the fact that the bowel may become so thinned by ulceration as to give way readily under the influence of anything approaching to violent action. It is perhaps unnecessary to point out that intestinal perforation attended by passage of fæcal matter into the peritoneal cavity practically means death for the patient. Now, when we reflect that this irritation of the stomach and small intestine is not only useless, but dangerous when we reflect further that this annoyance and risk are incurred in order to cause the evacuation of the rectum, and when we remember that the rectum can be at once relieved without this objectionable roundabout method, it seems to me that enough has been said to condemn the use of purgatives for the relief of constipation in enteric fever.

ADVANTAGES OF ENEMATA.

1. *The enema accomplishes all that you want—namely, the evacuation of the rectum.*—It is in the rectum that we find the hardened fæces which give the poor patient so much misery and distress. The accumulation of hardened fæces in the rectum is a fertile source of mischief and suffering to the enteric patient. If he is afflicted with hæmorrhoids the passage of such a motion gives rise to agony, and it may be loss of blood. The better plan is to avoid this mischievous state of matters; but when the evil has occurred, the quickest and most effectual means of relief is the administration of a copious enema of warm water and soap, with the addition, perhaps, of olive or castor oil.

2. *The relief is practically immediate.*—This is a matter of great importance. You wish to get rid of the source of irritation at once.

3. *The relief is obtained without any disturbance of the higher portions of the alimentary tract, as a rule.*—In conclusion, I do not mean to say that the use of mild, or it may be severe, purgatives in the treatment of enteric fever must necessarily be followed by fatal results, or even alarming symptoms; but I do mean to say that the practice is fraught with danger, especially in the advanced stages of the disease; and I contend that by the employment of enemata we attain our object without subjecting our patient to unnecessary suffering and danger.

NORTH - WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of this society was held in Manchester on the 16th inst. Dr. Kenyon of Chester succeeded Dr. McNicoll as president, Dr. Hughes of Ashton-under-Lyne was elected vice-president, Dr. Pettinger of Stretford, treasurer, and Dr. Vacher was re-elected secretary. The new President read a paper on "The Medical Officer of Health and his Work," in which he alluded to the immense advance recently made in the microscopic pathology of infectious diseases, as affording a prospect of mitigating the ravages of such diseases as measles and scarlet fever. The subject of the contamination of milk then came on for consideration, and it was agreed that Dr. Vacher should be asked to prepare a paper on it, to be read at the next meeting, and in which should be embodied the proposals contained in a memorial on the question to be sent to the President of the Local Government Board.

GUY'S HOSPITAL.

COLLOID CANCER OF RECTUM; SUCCESSFUL COLOTOMY; SUBSEQUENT PERFORATION AND SUPPURATION OF CÆCUM; PERITONITIS; DEATH.

(Under the care of Mr. Bryant.)

For the following notes we are indebted to Mr. Wright.

Alice W——, aged twenty-five, a barmaid, was admitted into Lydia ward on July 20th, 1880. Seven months before admission the patient was very costive for about a week, and this costiveness was followed by diarrhœa, which continued until February, when a medical man saw her. The diarrhœa frequently recurred. At first the motions were chiefly slime, but for the last three months she had passed clots of blood with fæces, and during this time she had amenorrhœa. She suffered a good deal of pain at night; she looked pale and weak. On pressing the abdomen several hard lumps could be felt, and a growth was discovered in the rectum.

On Aug. 6th, under chloroform, an oblique incision was made midway between the crest of the ilium and the last rib, about six inches in length. The colon was opened, and the edges secured to the margins of the abdominal wound with strong sutures. The edges of the wound were then brought together again. Next day the patient expressed herself as feeling more comfortable; wound very healthy. On the 9th she was much more comfortable. Temperature 99°. On Aug. 11th the temperature was 95·5°. On the 12th the temperature was 97·8°; had a bad night; motion streaked with blood. It was about her menstrual period. Next day she was better again, and fæces passed through the artificial anus. On the 16th she was in a good deal of pain in the abdomen during the night, the pain having come on suddenly over the right iliac fossa. On the 20th she was very ill, and in much pain, which continued all next day. Although a good deal of fæcal matter has passed through the artificial anus and rectum, there was much fulness with tenderness over the cæcum. Under chloroform a transverse incision was made into the cæcum. A quantity of fluid escaped, but nothing hard. A finger was then passed into the opening, and afterwards a director was put in, and a second opening made through the front of the abdominal wall. Patient derived but little benefit from this operation, and died in the afternoon. Relief was given too late.

Necropsy.—General suppurative peritonitis. The anterior wall of the rectum, three inches and a half from the anus, was occupied by a growth running transversely, and occupying two-thirds of the circumference of the bowel. The surface was ulcerated, and showed the growth to be a colloid cancer. In the mucous membrane below the ulcer was a round prominent mass, movable, and covered by mucous membrane. On section, it was a deep red, with translucent patches. The rectum was adherent anteriorly to the uterus and its ligaments, and in two places the wall of the gut was perforated, and little abscess cavities containing fæcal matter existed, bounded by the uterus and broad ligament, and the adhesions. From this situation the inflammation had become general. One ovary was in the wall of a fæcal abscess, and had softened down into a grumous puriform fluid. The operation wound was found healed and healthy. The lumbar glands were involved. There were no secondary deposits.

CARCINOMA OF RECTUM; COLOTOMY; RECOVERY.

The following notes have been furnished by Mr. Row.

Eliza C——, aged twenty-nine, was admitted into Lydia ward on Jan. 29th, 1880. Four months before admission she had much pain in passing motions, which were streaked with blood. A white medicine given by a doctor did not relieve the bowels, but an enema gave relief. About the same time the abdomen began to swell, and became very painful, particularly in the left inguinal region and rectum. Bougies were repeatedly passed.

On admission the patient was very emaciated and feeble. The abdomen was retracted, and scybala could be detected in the left inguinal region. About an inch from the anus a hard mass could be felt constricting the passage of the rectum and preventing the finger from passing. By the vagina the mass was found to extend beyond the reach of the finger.

On Feb. 3rd, under ether, colotomy was performed. On the 7th the patient was comfortable. She had taken milk and soda-water. No motion had passed through the wound, but on the 9th some passed. She took some chicken. On the 15th the wound had healed by first intention. On the 18th she complained of pain in the abdomen, and on manipulation some hard masses could be felt, and there was a hard and tender spot in the inguinal region. On the 20th the patient was in a good deal of pain; the intestines were full of fæces. On the 27th there was pain in the abdomen; scybala very prominent. An injection was given through the artificial anus; nothing passed through the rectum.

On March 11th a large quantity of fæces came away by the artificial anus. On the 17th she went out. She passed motions comfortably by the artificial anus.

On June 5th she was doing well and had gained much flesh.

CANCER OF RECTUM; COLOTOMY; RECOVERY.

For the following notes we are indebted to Mr. Row.

Mary Ann T——, aged fifty-nine, was admitted into Lydia ward on Dec. 3rd, 1879. She had a good family history, with no knowledge of cancer. About May, 1878, patient began to suffer from constipation; she had had great difficulty in passing her motions. At night a discharge mixed with blood escaped per rectum. There is no pain in the region of the anus, but for months she suffered from pain across the lower part of the stomach.

On admission, patient was a short, healthy-looking woman. In left inguinal region lumps could be felt, but whether growths or scybala could not be made out. Tongue normal. Oil administered.

On Dec. 9th, under chloroform, an incision was made for colotomy. When the finger was inserted, the part of the colon to be stitched to the side of the wound was found to contain a large scybalum. The needles were inserted through this, and the bowel opened without removing the mass. She was sick several times after the operation. There was no attempt of the scybalum to come through the wound; no bleeding per anum. On the 13th there was no pain or tenderness of abdomen; slept fairly well; wind passes through wound. Fish diet. On the 16th some fæcal matter passed through the wound, and three days later fæces passed through the artificial anus. On the 21st an enema was given per rectum. The fluid came up and escaped at the artificial opening. Next day a mass of well-formed motion was lying outside the artificial anus. Patient appeared very well, but complained that she did not micturate freely. On the 29th there was some fæcal discharge per rectum, which patient said gave much pain. There was also prolapsed colon through the artificial anus, to the extent of about half an inch, about the size of half a walnut. Ordered an injection of warm gruel and olive oil at once and at bedtime.

On Jan. 6th, 1880, fæces passed freely through the wound, which looked very healthy. On Jan. 21st she left the hospital. The carcinomatous growth of rectum was less painful than it had been. She had had a plug made, which kept the upper slightly prolapsed portion of the colon in its place.

INTESTINAL OBSTRUCTION; COLOTOMY; RECOVERY.

For the following notes we are indebted to Mr. Underwood.

John E——, aged thirty-eight, a wharfman, was admitted on July 16th, 1880, into Job ward. The patient was married, and the father of seven children. He had scarlet fever in 1866. In 1877 he had diarrhœa, which continued more or less. In November, 1879, he had a good deal of pain, and became costive for a time. A medical man gave him some pills, and the diarrhœa returned, and continued until admission, when it was accompanied with pain, and he applied and was admitted into Stephen ward, from where he was transferred to Job ward. He had had obstruction for about three weeks, and, in spite of medicine, was getting worse. His abdomen was greatly distended and somewhat tender, and his powers were rapidly failing; indeed, he was so low that the propriety of operating was carefully discussed. Mr. Bryant, however, determined to give him the relief which an operation would afford.

Under chloroform left lumbar colotomy was performed, the usual oblique incision being made. He slept well and long; had not much pain next day. On the 24th the discharge had nearly ceased; bowels acted well through anus. On the 28th the edges of the wound were healthy, and healing very nicely; health good. On August 2nd he got up, and on the 11th a belt was ordered. The temperature was normal throughout.

The relief which the operation afforded this patient was striking and rapid. He convalesced without one bad symptom, and when he left the hospital he was quite comfortable.

WANDSWORTH INFIRMARY.

FOUR CASES OF SPINAL CARIES, WITH SUPPURATION NOT PRESENTING EXTERNALLY; NECROPSIES.

(Under the care of Mr. JAMES ALLAN.)

CASE 1. *Caries of dorsal spine; paraplegia.*—William S——, aged sixty-nine, was admitted on Dec. 29th, 1879. In December, 1878, after exposure to cold and wet, the patient felt pains across the lower part of the back. This did not incapacitate him from acting as a messenger until nine months later, when the inferior extremities became weak and dragged slightly. Sensation was impaired; numbness, first noticed in the toes, crept up both limbs simultaneously. He had slight starting of the limbs, chiefly at night, straining on micturition (urine passed most freely in the morning), and soon afterwards constipation. Rapid increase of these symptoms took place during the week preceding admission, but he was not confined to bed. On examination, motor power and sensation of the lower limbs were very limited, and reflex action was increased; there was pain in the lumbar spine; the patient could sit up in bed without difficulty. The urine was normal; bowels constipated. On Jan. 12th he had retention of urine, necessitating the use of a catheter. On the 17th he had complete motor paralysis, with painful starting of limbs. On Feb. 1st incontinence of urine came on; the bowels were moved only by enemata. On the 19th the urine was ammoniacal, and there was a sensation of constriction round the abdomen, together with prominence of one of the lower dorsal spines. On March 19th the skin over the sacrum had given way; there was much pain shooting round the upper part of the abdomen from the level of the two lower ribs; sensation of the limbs was quite abolished; reflex action increased; anorexia. On March 25th the patient died exhausted. He was easiest when propped up in bed; pain was relieved by opium and by small blisters applied near the spine; temperature subnormal.

Necropsy.—Removal of the thoracic viscera exposed at the lower part of chest, two rounded tumours, one on each side of the bodies of the tenth and eleventh dorsal vertebræ; contents fluid, and communicating with each other across the middle line. Incision showed that each contained about an ounce of thick pus, mixed with bone fragments; that the cartilage between the tenth and eleventh vertebræ had disappeared; that the tenth vertebra was eaten away in its lower surface, but to a much greater extent anteriorly than posteriorly, and presented an irregularly convex outline, fitting into a corresponding concavity in the upper surface of the eleventh vertebra, which was not much wasted; and that the opposed surfaces were tolerably firm, covered here and there with small patches of cartilage. The tenth dorsal spinous process was slightly prominent; on removing the spinal arches the body of the tenth dorsal vertebra was found projecting somewhat backwards inferiorly. Above this projection the membranes and cord were normal; below, the dura mater was much thickened, and adherent to the spinal canal by means of an inspissated layer of pus, mixed with bone spicula; the cord was slightly softened, but not adherent. At apices of lungs there was evidence of old cured lung disease; bladder hypertrophied; pus in pelvis of left kidney; small granular kidneys.

CASE 2. *Caries of twelfth dorsal and first lumbar vertebræ; no paralysis.*—Henry C——, aged fifty-five, was admitted on Sept. 3rd, 1879. About four years before he fell from a considerable height on his back; for the last two years he had experienced weakness and pain in the lumbar region. On examination, the last dorsal spinous process was slightly prominent; pain on pressure or movement, and rigidity of the spine were also noted. The urine was normal. While under treatment he frequently had intractable pain in the area supplied by the lateral branch of the last left dorsal nerve. The movements of the left thigh caused pain, and he could not turn readily in bed. No paralysis or difficulty with bowels or bladder; occasionally free of pain; not usually confined to bed. He was relieved by chloral and by blisters; his condition was aggravated by opium. Died rather suddenly of pneumonia on May 30th, 1880.

Necropsy.—The right lung weighed fifty ounces, and was in a state of red hepatisation. There were caseous nodules in the apices of both lungs. There was prominence of the twelfth dorsal spinous process, and slight displacement backwards of the twelfth dorsal vertebra. Over a limited area anteriorly, opposite a large carious cavity in the contiguous surfaces of the twelfth dorsal and first lumbar, the dura mater was thickened, and encrusted with a layer of thick pus and bone spicula, and adherent to the spinal canal. Cord normal. On dissection from the abdomen it was found that no disc existed between the above-mentioned vertebræ, and that a large portion of both bodies had broken down; the space so formed was occupied by thick pus and bone débris; pus had burrowed along each side of the spine in the psoas muscles as far as the third lumbar vertebra; the greater quantity of pus was on the left side, tilting forward the left kidney. The upper surface of the first lumbar presented a concavity excavated to almost the whole depth, and the under surface of the twelfth dorsal was so fashioned as to fit into it. The carious surfaces were soft, and readily broken into. Large white kidneys, 7 oz. each. Liver, 4 lb., fatty.

CASE 3. *Superficial caries of fourth and fifth lumbar vertebræ; tuberculosis.*—James W——, aged sixty-seven, was admitted on April 30th, 1880, on account of a carious cavity in the shaft of the right tibia, near the upper extremity, of ten years' duration. While under observation he was feeble; appetite poor; lost flesh and complained of pain across the lower part of lumbar spine. His chest was emphysematous, but nothing further was detected until a few days before death, when crepitation, dry and small, was heard all over both chests; resonance not impaired. Ten hours before death, on August 5th, 1880, he had a series of convulsive fits, and became unconscious; the fits recurred frequently; consciousness was not recovered; convulsions general and rather violent.

Necropsy.—Several minute hæmorrhages were found in the course of the vessels at the base of the brain, and especially in the Sylvian fissures, none in the cerebral tissue. Both lungs free in the chest; right weighed 29 oz.; left 22½ oz.; both throughout in a state of acute miliary tuberculosis. Heart weighed 10 oz.; right auricle contained a large firm white clot; valves competent. Liver, spleen, and kidneys amyloid; in the liver and kidneys there were several minute purulent collections. Superficial caries of the fourth and fifth lumbar vertebræ anteriorly, and connected with the bare bone about 3 oz. of pus, thick, not mixed with bone fragments, in each psoas muscle, running in the direction of the muscular fibres, and causing considerable destruction of tissue. The carious cavity on the inner surface of tibia reached deeply into the head of the bone.

CASE 4. *Caries of dorsal spine; paraplegia.*—Mary H——, aged sixty-eight, was admitted Dec. 8th, 1880. For three weeks she had felt ill, and on admission exhibited symptoms of gastro-hepatic derangement, foul tongue, tenderness on pressure over stomach and liver, nausea and constipation. The urine was slightly alkaline. On Dec. 14th she had neuralgic pains in the left upper part of abdomen, relieved by blisters applied near the spine. Two days later there was pain on pressure over the lower dorsal vertebræ. On Jan. 27th there was some loss of motor power in the lower limbs, attended with cramp; the bowels were confined. On Feb. 2nd there was complete motor paralysis of inferior extremities, abolition of sensation, sole reflex subnormal, patellar phenomenon normal, painful involuntary flexions of the limbs (pain referred to spine, hips, and abdomen), and loss of sensation in lower part of abdomen; incontinence of urine; bowels moved only by enemata. On Feb. 9th there was flatulent distension of the abdomen. The pain was relieved by opium. Later the patient had a bedsore; for the last month the bowels acted spontaneously. Death took place from œdema of the lungs on April 24th, 1881. A daughter died of hip-joint disease, and a son of hæmoptysis; no history of injury.

Necropsy.—After removal of the spinal arches, on raising the dura mater, it was found adherent anteriorly to the body of the seventh dorsal vertebra, much thickened at this part, and encrusted with caseous pus. At the seat of this lesion the cord was slightly softened and considerably lessened in bulk, but not adherent to the membranes; carious cavity in seventh vertebra. A small soft tumour behind the descending aorta indicated the situation of the affected vertebra, and was due to a local collection of thick pus and bone fragments occupying the cavity in the body of the seventh vertebra, and bulging anteriorly. With the exception of the upper and lower epiphysal plates, the body of this vertebra was almost entirely removed; the intervertebral fibro-cartilages not affected. Lungs emphysematous and œdematous at dependent parts; weight of uterus two ounces, a multilocular par-ovarian cyst on the right side, size of a large orange; the left ovary was implicated in a simple cyst of like dimensions. Great intestine much longer than normal. Fourth ventricle of brain small, central canal not patent at the calamus scriptorius.

Remarks.—It is held that in spinal disease, if cartilage be primarily affected, there is less likelihood of suppuration than when disease commences in bone, and hence the non-occurrence of suppuration is regarded as diagnostic of cartilage disease. The practical value of this distinction is limited by the fact that until pus reaches the surface the state of parts as to suppuration is conjectural. The above cases sufficiently indicate that pointing of pus on the surface of the body is a consummation that may never take place.

Reviews and Notices of Books.

Neurological Contributions. By WILLIAM A. HAMMOND, M.D., assisted by WILLIAM J. MORTON, M.D. No. III. New York: G. P. Putnam's Sons. 1881.

THE third part of these "Contributions" consists of papers entirely by Dr. Hammond, Dr. Morton having disappeared, except from the title-page. The essays are of considerable interest. The first is on "Thalamic Epilepsy." By this term Dr. Hammond designates cases of epilepsy in which there is little or no convulsion, but which are preceded by a visual hallucination. Several of the cases narrated are very striking, but, except in the variability of the warning, they differ little from the not rare cases of epilepsy with a visual aura, and certainly do not possess the unique character which is here ascribed to them. The name given is an embodiment of the theory, put forward in the paper, that the attacks depend upon a morbid state of the optic thalamus. The evidence that this is the seat of the disease is not satisfactory; it certainly is far too slight to justify the designation. The chief support is derived from one or two pathological cases in which hallucinations were associated with actual disease of the thalamus, but this does not at all exclude the possibility that the morbid process underlying the hallucinations occurred in the convolutions, which were in one case also diseased. There is no ground for Dr. Hammond's absolute and dogmatic assertion that "the cortex, or intellectual centre for any sense, cannot form a real or false sensorial impression," but can only judge of the reality or falsity of impressions formed in the optic thalamus, so that the difference between a visual delusion believed to be true and a visual hallucination recognised as false, is that in the former case the cortex is diseased, in the latter it is healthy. We are very far at present from such a knowledge of the physiology of the brain as would justify any similar distinction, but the preponderance of evidence is strongly against the theory, and tends to show that many illusions recognised as false may take origin in the cortical sense centres.

The second paper, on Neuralgia of the Testis, is of a more practical character. The paroxysmal character of the pain, and its relief by firm pressure, are the points relied on by Dr. Hammond in the distinction from the irritable testis of previous writers. The object of the paper is specially to point out the thrapeutical importance of compression of the spermatic cord, which, it is said, will effect a cure without causing any damage to the organ. The pressure must be firm, as a slight degree increases the pain, while greater pressure will arrest it.

After a description of an interesting case of myxœdema comes a startling paper on the therapeutical use of the magnet. The results obtained in France are equalled, if not exceeded, in New York. Attention is drawn to some curious observations by Dr. John Vansart, formerly of the United States Army, on the influence of the different poles of the magnet on hyperæsthetic parts, and which appear to have led Dr. Hammond to use it largely in the treatment of neuralgia. The facts described in this paper relate to chorea and paralysis. In seven out of nine cases of chorea no result followed. In the other two cases "complete cures were produced in a few minutes." In one, for instance, we are told that a little girl, aged ten, came under treatment with chorea of seven weeks' duration. There were "violent jactitations of all the limbs and of the muscles of the trunk and face. She had lost the power of speech." Very large horseshoe magnets were applied to the spine and the sternum at 1.30. At 1.55 all choreic movements had ceased, at 1.57 she spoke a few words, and at 2 spoke well. The magnets were then removed and the cure was permanent! Even more astonishing, however, were the results in cerebral hæmorrhage. We are told of complete anæsthesia from this cause removed entirely in seven minutes, and hemiplegia in three hours, by the application of a horseshoe magnet! Dr. Hammond, however, recognises, at the end of his paper, that the results may possibly not be due to any specific influence of the magnet, but may be owing to the strong mental impression, or may have been coincident, a recognition with which some of the language employed in an earlier part of the paper is scarcely consistent.

The concluding papers are a series of useful suggestions regarding the management of the insane in asylums, and an account of some "cases of obscure abscess of the liver; their association with hypochondria and other forms of mental derangement, and their treatment."

Medical Education and Practice in all parts of the World. By HERBERT JUNIUS HARDWICKE, M.D. London: J. and A. Churchill. 1880.

WE are constantly asked questions about the regulations in foreign countries touching medical qualification and graduation. This book contains a fund of information on such matters, as well as on the regulations of British medical authorities. The whole is preceded by an introduction, which is worth the attention of all persons taking a broad interest in medical education, in the international recognition of degrees and other qualifications. The arrangement of matter admits of some improvement. The index is imperfect. Some weaknesses in home and foreign regulations are too lightly passed over. And it may well be that such a mass of statement will, on experience, be found to be defective at points. But we accept it gratefully, as an attempt to supply a very great want, and we commend some of the reflections of the author on the defects of our own system to all whom it may concern.

THE NEW ST. MARYLEBONE INFIRMARY.

THE new infirmary buildings at Notting-hill, which are to be formally opened on the 29th inst. by the Princess of Wales for the reception of pauper patients of the parish of St. Marylebone, are the latest addition to the series of sick asylums which have been erected under the provisions of what is best known as the Gathorne Hardy Act of 1867, a statute which THE LANCET was mainly instrumental in promoting. Previous to the passing of that Act the condition of sick paupers in the crowded, dark, dingy, ill-ventilated infirmary wards attached to the workhouse buildings was most deplorable, the medical attendance was very inadequate, and the nursing almost entirely entrusted to pauper helps. Attention was repeatedly drawn in our columns at that time to the grave abuses that existed, and the articles of the late Dr. Anstie, who conducted the inquiry on our behalf, roused such a feeling of indignation and horror among all classes of the community, that a large measure of reform was at once insisted on. So that before the provisions of the Act could be carried out by the erection of new infirmaries it was apparent that public opinion had made itself felt, and even in the close overcrowded wards of the old buildings improvements were effected which made the condition of the inmates more tolerable and successful medical treatment possible. Since, however, the opening of the new sick infirmaries, distinct from the workhouse buildings, which now afford accommodation for over 10,000 of our sick poor, nothing is left to be desired with regard to the sanitary and hygienic arrangements and general management, and the provision of necessary appliances for the sick. Pauper nurses are things of the past, and trained nurses under responsible supervision have taken their place, whilst resident medical officers are appointed whose duty it is to devote themselves solely to the work connected with the infirmary; instead, as was too often the case under the old system, of the medical officer living away from the buildings and giving what time he could spare from the demands of his private practice. And although the salaries attached to the posts have not been calculated on a very liberal scale, it is satisfactory to find that hitherto they have proved sufficiently attractive to induce good men to come forward for them.

Some surprise has been expressed that such a wealthy and influential parish as St. Marylebone has been so tardy in following the example set by other, and in many cases smaller and poorer unions. It had long been felt that the infirmary wards in the present workhouse were sadly inadequate for the purpose; whilst during the severe winters of 1878, 1879, and 1880 the wards were dangerously overcrowded—indeed, often so overflowing that cases had to be sent to the infirmaries of other workhouses. The delay, we are assured, was not caused by any desire to evade making adequate provision for their sick inmates, but arose from the difficulty that was found in obtaining a suitable site for the new buildings. This, we believe, was a matter of anxious consideration, since sufficient space could not be obtained in the parish itself without incurring great cost, and it was ultimately determined to erect the infirmary at some distance from the workhouse. The present site seems in every respect a suitable one. It is situate at the western extremity of the Ladbroke-grove-road, and the time occupied in transit from the door of the workhouse to the new infirmary by the Underground Railway is about half an hour. The neighbourhood, too, is not yet encumbered by buildings, and the western and northern aspects of the infirmary still look over green fields, the former over Wormwood Scrubs, the latter towards Kensal-green. The infirmary stands on the top of a slight ridge which slopes abruptly down to the fields below. The buildings are arranged on the pavilion plan in the form of blocks, communicating with each other by means of covered ways. Each block contains two pavilions, and each pavilion three wards. The wards are all of the same size and arranged on the same plan. Each contains twenty-eight beds, and its cubic capacity is 24,192 feet, or 864 cubic feet for each bed. The wards have fourteen windows, seven on each aspect, nearly due west and east, fitted with venetian blinds. The walls are coloured French grey, with a shade of Indian red, and are light, cheerful, and well proportioned. The bedsteads are of iron, furnished with a straw palliasse and a hair mattress, a bolster, and a feather pillow. Two or three large chairs, made of polished pine, after a design of the Master of the Marylebone Workhouse, are placed in the centre of each ward and give it a furnished look. Strips of grey "calmuck" are laid over the floor, and add greatly to the appearance of general comfort. The wards are heated by two of Mr. Saxon Snell's "thermhydric" stoves, which also serve as means of introducing fresh air continuously from without into the wards. In addition, each pair of beds is provided with a system of ventilation of its own. If any pair of beds be moved forwards into the room, it will be seen that next the wall there is a skirting-box with a panelled front, and that the panels immediately under the heads of the bed are formed of perforated zinc. This box covers an aperture in the floor, from which a ventilating pipe descends in slanting direction to the outside of the wall, through which the external fresh air is admitted. In the ceiling over each pair of beds there is another perforated zinc panel running the whole width of the ward, covering a channel (depth 12 inches) which communicates with a large shaft running up the wall like an ordinary chimney flue. By this the foul air is removed. At the end of each ward is a lavatory, with two closets, sink, washing-basin and warm-water bath, all in separate compartments. In addition, each ward has a "separation" room for the treatment of noisy or delirious patients, or for the isolation of infectious cases. The nurse, too, has a "duty" room, where the materials and requisites for ward work may be kept in store; whilst for every two wards there is a day-room for convalescent patients.

The nursing is entrusted to a staff of nurses under the Nightingale system. Each pavilion will be supervised during the day by a head nurse, who will have under her charge three ward nurses, one for each ward. The night nursing will be, for the whole building, entrusted to one head nurse, with one night nurse for each pavilion, a scanty allowance, though it will be eked out no doubt by the employment of scrubbers and cleaners. Over the whole staff will be placed a lady superintendent. Each nurse will have a separate bedroom, and these apartments have been placed in the administrative part of the building away from the wards—a wise and wholesome proceeding. The medical staff consists of a resident superintendent, and an assistant medical officer and a dispenser.

The general domestic arrangements seem to be excellent, and all the necessary appliances have been liberally supplied. The kitchens, larders, laundries, &c., are all constructed on the most approved principles. Each pavilion has its own hydraulic lift, and each floor of each pavilion is furnished with a powerful hydrant. The mortuary and post-mortem room are distinct from the blocks containing the wards; they have, however, been erected a little too close to the administrative block. The water-supply of the establishment is obtained from an artesian well sunk on the premises to the depth of 500 feet, of which 211 feet are in the chalk. In this way a supply, which it is reckoned will yield 4500 gallons per hour, of pure and excellent water is obtained. In this respect the paupers of St. Marylebone have an advantage over the ratepayers, who have still to put up with sewage-tainted Thames water purveyed to them by the West Middlesex Water Company. The drains from each block enter a sewer which lies between two blocks and discharges into the main drainage outside the building. No special provision is made for ventilating these drains except by means of the water-pipes. This is a dangerous practice, especially as those water-pipes pass close to the ward windows, and it cannot always be expected that the joints of these pipes will remain as closely attached as at present, or that the drains of a large institution will always remain in perfect order. It would therefore be advisable to secure efficient ventilation of the drains of each block by means of a special channel, and discharge the water-pipes over gratings, instead of directly into the drains. This and the situation of the mortuary are the only two points in the building on which we can raise any objection, and these can be easily remedied. We think, therefore, Mr. Saxon Snell, the architect, may be fairly congratulated on the result of his labours in the erection of an infirmary equal to any of its class, and which, in many of its details and arrangements, would compare favourably with those of a first-class hospital. Acknowledgment, too, is due to Mr. Edward Boulnois, chairman, and Mr. Bedford, the clerk of the St. Marylebone Board of Guardians, for the personal attention they have given to all matters of detail whilst the works were in progress.

In conclusion, we would point out how in some respects these sick asylums might be rendered still more advantageous to the inmates, as well as to the community generally. In the first place, their usefulness, as we have repeatedly pointed out, is checked by the fact that at the present moment no distinction is made between the *sick poor*—that is, the industrious mechanic who has broken down in health whilst endeavouring to maintain himself and family by honest labour—and the *sick pauper*, the regular inmate of the workhouse. This is a great evil, and is in itself a fertile cause of pauperism, since many a respectable man in his endeavour to avoid the taint of pauperism struggles on outside till an acute disease becomes a chronic one, and ultimately he becomes a permanent instead of a temporary burden on the rates. In these sick asylums much might be done to remove the dislike felt by the respectable poor to becoming inmates if some classification were adopted by which sick paupers and the sick poor were kept distinct. If the St. Marylebone guardians were to try the experiment of setting aside one of the blocks entirely for the use of acute cases occurring among the respectable poor of their parish, they would confer an immense boon on this class, and we believe they would speedily be rewarded by restoring many a working man to health and activity by inducing him to come for relief at an early period of his illness, instead of postponing it till obliged to enter it in an incurable condition.

Then with regard to the nursing system, whilst fully admitting the immense advantage gained by the substitution of trained nurses for pauper helps, we are far from saying that the nursing staffs of these asylums are sufficient to cope with the vast amount of labour entailed by the attendance on the chronic cases which abound in these institutions. In addition to the staff of nurses already engaged, there ought to be at least two probationers attached to each ward. The system of nursing at our workhouses might be made almost self-supporting if the wards were rendered available for the systematic training and education of nurses to supply the requirements of our metropolitan hospitals and the public generally. Such a training could, certainly in its first stage, be more efficiently conducted in the comparative quiet of the infirmary wards than amid the bustle of a large metropolitan hospital; whilst the experience gained in the management of bedridden cases and routine treatment of chronic hopeless cases would be an invaluable training for the young nurse. The experiment, thanks to the enterprise of Mr. Rathbone, has been tried at the Liverpool Workhouse, and has proved completely successful.

Lastly, we would point out how inefficient these infirmaries are with regard to subsidiary clinical assistance. In this respect they are worse off than they were twenty or thirty years ago, when the apprenticeship system generally ensured a staff of assistants who in some measure helped to compensate for the shortcomings of the pauper helps in the nursing department and the hurried visits of their principals. Notwithstanding the appointment of efficient medical officers, who devote the whole of their time to their patients, it is impossible for two men to do anything like justice to 400 or 500 cases. From our own experience of workhouse infirmaries we would say that, in an ordinary institution, it would require the work of two men alone to attend to the proper electrical treatment of the disorders of the nervous system which are so common among the inmates. But if the treatment is to be something more than a pretence, how can the medical officers find time for other duties, such as the constant care and watching that chronic pulmonary affections require, if they hope to relieve the ever-varying forms of suffering these successively pass through, to say nothing of the attention required by stricture cases, chronic bladder affections, ulcerated legs, &c.? How in the case of the new St. Marylebone Infirmary only two medical officers are efficiently to perform a tithe of their duties to the patients with the care of twenty-four wards of twenty-eight beds each, we are at a loss to conceive, unless the guardians provide additional clinical assistance in the form of clerks and dressers.

THE GOVERNMENT INQUIRY INTO CAUSES OF SUMMER DIARRHŒA.

To the Editor of THE LANCET.

SIR,—Will you permit me to address you, and through you my medical brethren about the kingdom, on the subject of the large and most important inquiry into the etiology of "summer diarrhœa," with which the Local Government Board has charged me.

It is an official inquiry, but from the first I have perceived that it would be impossible, even if it were desirable, to conduct it altogether through official channels. Naturally, I have looked for help, first of all, to Medical Officers of Health. Among these there are many earnest workers with whom I am personally acquainted, whose willing aid in the collection of facts I have enlisted, and who are taking upon themselves much labour in my behalf. Through Medical Officers of Health I am seeking to obtain such minute details of statistical information respecting mortality as are necessary for my purpose. There are many of these officers with whom I have been anxious to confer, but time and opportunity have been against me. I shall be glad of volunteers.

But there is another and important class of facts, which can only be supplied by men engaged in medical practice—namely, facts which relate to summer diarrhœa as a disturbance of the system of the individual, or a *disease*, fatal or non-fatal. As such it is met with in all ranks of society, and at all ages, although its fatality is apparently greatest in certain ranks, and at certain ages. Various hypotheses have been advanced to account for the summer incidence of the disease, and for differences in its fatality, and all these hypotheses will have to be passed under consideration. My difficulty is to obtain data, accurate and sufficiently numerous, to enable me to estimate their value; and for these data I now make an appeal to the members of my own profession, in the full belief that there are many among them who will feel an interest in the subject, and that I shall not appeal in vain. Especially I beg for aid from such of my brethren as practise among the well-to-do classes of the community. I particularly want to discover whether summer diarrhœa is a disease of equally frequent occurrence among the well-to-do and among the poorer classes, the rate of fatality of it when it does occur among different classes of people, and the circumstances under which the illnesses happen.

In order to facilitate the giving of the information I require I have prepared, and am now issuing to those practitioners who will kindly help me, small pocket note-books, patterns of which I enclose. I think you will see that in these books I have reduced my actual specific inquiries to a minimum. One of the books is for the record of individual cases of diarrhœa sickness; the other is complementary to it, and has for its object to ascertain with some approach to accuracy what is the practice of mothers in respect of the feeding of infants at different ages, in different ranks of life, and in different parts of the country. Any required number of these little books will be furnished to medical men who are willing to use them, on their writing for them to me at the Local Government Board, Whitehall.

I am, Sir, yours, &c.,

EDWARD BALLARD.

Local Government Board, June 20th, 1881.

THE LANCET.

LONDON: SATURDAY, JUNE 25, 1881.

The forthcoming election of members of Council of the Royal College of Surgeons is likely to be unusually keen and exciting. There are not only twice as many candidates as there are vacancies, but almost everyone of the candidates happens to possess some peculiarity or characteristic calculated to split up the electing Fellows into contending factions. All parties may, perhaps, combine to secure Sir James Paget's election, but there everything like general agreement and co-operation may be expected to cease. For example, there is, we believe, a small party of Fellows willing to see Mr. Haynes Walton re-elected; another section, much larger and more intelligent, is very properly anxious to show its appreciation of Mr. Hulke's merits as a tried friend and servant of the College, as an eminent surgeon, and as a distinguished man of science; another, appreciating Mr. Croft's amiable qualities and his reputation as a sound teacher and practitioner of surgery, would be glad to see him elected as a sort of successor to his *quondam* colleague at St. Thomas's Hospital, Mr. Le Gros Clark; another section, recognising Mr. Heath's services to the College as an examiner, and his well-known business capacities, will spare no effort to secure his election; and, lastly, that section of Fellows which perceives some irreconcilable difference between the interests of surgery as practised in the provinces and in the metropolis, will exert itself as heretofore to secure the election of Mr. Reginald Harrison of Liverpool. Though it is not easy to understand the reason of the fashion of electing every year a provincial candidate, the practice has grown to such a degree that it is now deemed almost a point of honour among Fellows residing out of London to vote for the provincial candidate. If the election of a provincial candidate were only an occasional circumstance, and intended as a mark of esteem to some distinguished Fellow practising in the provinces, it would be a graceful act, and altogether unobjectionable; but the practice of bringing forward every year a candidate resident in the provinces, and especially a *junior* Fellow, is reprehensible, and is likely, sooner or later, to disturb the harmony that has hitherto existed between all classes of Fellows. At the present moment five of the twenty-four members of the Council are Fellows residing in the provinces. Even after the retirement of Mr. Wheelhouse, the provincial Fellows will constitute one-sixth part of the Council. This means that the working power of the Council is limited by this amount, inasmuch as it is scarcely practicable to place those members of the Council who live away from London conveniently on the various committees that practically conduct the business of the College. These labours devolve therefore upon the metropolitan members of the Council, many of whom are known to attend almost daily upon the affairs of the College.

Election into the Council of the College should not be looked upon as a mere compliment or professional honour. The duties of a member of the Council are of such a nature that they can only be safely entrusted to men of known fitness and capacity. The Royal College of Surgeons is now the chief examining body in this country for regulating and controlling the average education of the medical student. The continued defection and decay of the Royal College of Physicians may soon leave it practically without a rival. It is, therefore, of the first importance that those who are elected into the Council to manage its affairs should be familiar with all the phases of medical education and of medical reform. It needs no argument to prove that a man may have earned an enviable position as a practitioner of surgery, and yet be wholly unfit for the duties that devolve upon a member of the Council of the Royal College of Surgeons. It is especially desirable just now to elect only competent men. During the ensuing year many important questions affecting medical education will have to be considered by the Council, and not only the ultimate welfare of the College, but the immediate interests of medical education, may depend on the attitude assumed by the Council towards some of these topics. The Royal Commission on the Medical Acts, now sitting, is not likely to leave things exactly as it found them. Many important changes will be recommended, and these recommendations will have to be considered in a frank and liberal spirit by the Council.

The attitude taken by the Royal College of Physicians with regard to the Medical Acts Commission is not encouraging for the speedy settlement of the long-burning question of medical education; and although the resolutions passed last week were not quite so uncompromising as those originally framed, and the mode in which they are to be brought under the notice of the Commission was also modified in the right direction, they seem to exhibit too keen a desire for the retention of certain privileges of the College. The anxiety thus shown to impress the Commission with the fact that any diminution of these privileges will be detrimental to the public and the profession would have been pardonable in a less well-known body, but the College of Physicians of England, with its long and venerable history, might well have been content to rely on the work it has effected, and would have adopted a more dignified course had it allowed the Commission to find out for itself the value set upon its licence.

Of course it was natural that the College should be mindful of its own interests, and if it had always been so, it might not have been necessary to urge them now. If, instead of abrogating the powers conferred "by charter of King Henry VIII.," it had in past times acted upon them, it might never have been placed in this position; but having suffered these powers to drift, and aimed at creating a select body of high-class practitioners rather than at supervising the whole of medical education, it has come to be not the sole licensing body in the kingdom, nor even one of two, but one out of nineteen, enabled like itself to grant qualifying diplomas which in the eyes of the uninformed are all of equivalent value. It is easy to imagine the demand being made that the same measure should be meted to all, and if the interests of one corporation are to be attacked, why not the interests of all?

Let us see how far the interests and privileges of the College of Physicians are likely to be at stake, and the manner in which the College has chosen to defend itself. Before doing this, we may reasonably inquire how it came to pass that the College was called upon for defence at all. A courteous letter from the secretary to the Medical Acts Commission, asking for information other than that already obtained through the Select Committee, could hardly be the cause of such a flutter in the dovecote. The letter was harmless enough, and conveyed no hidden meaning between the lines, implying that a State Board was to be formed, and the interests of the College to be attacked. It was a circular letter addressed to all corporations, and why the College should, in considering it, have gone out of its way so far as to pass resolutions based upon a hypothetical scheme, is not apparent. It seems as if the College had taken fright at a phantom of its own creation, and whilst under the influence of this apprehension had magnified the proportions of a State Board till it appeared to overwhelm the College, and reduce it to impotence and insignificance. Suppose, however, there be truth in the surmise that the Commission will suggest a radical reform, and, disestablishing all the present licensing bodies, recommend the formation of a central State Board for the purpose of granting licences. The influence of such a board upon the profession generally is one thing, the effect it will have upon the corporations at present granting licences is another. It might well be argued that a State Examining Board, which should be the sole licensing body in the kingdom, would not be nearly as detrimental to the College of Physicians as to the majority of the corporations it would replace; for it is plain that were all these bodies of as high standing and repute as the College, there would be no need of a Commission to inquire into the working of the Medical Acts. There is no doubt that the College is right in believing that "the qualifications implied in the possession of its licence are adequate evidences of professional knowledge, and that its licence is esteemed alike by those holding it, by the whole of the medical profession, and by the public." It is, however, now looked upon as a distinction, and is only sought after by the better class of students, so that the medical practitioners holding its diploma form a minority in the profession. Even if the College were to abandon its licence-granting power, it would have as many candidates as before seeking the equivalent distinction which the College might still grant—for there would be as strong a desire then to obtain something more than the minimum qualification of a State Board. Other corporations might lose their *raison d'être*, and would probably be compelled to abandon their diploma-giving function altogether. It seems, however, as if the College of Physicians were desirous of possessing the power to confer the minimum qualification, a power it claims to have by right, but which it suffered to fall into abeyance, and that it aims at increasing its influence under a new dispensation.

The anticipation of what would follow the formation of a new Board may not be fulfilled as regards its effect on the number of licentiates of the College, so that the actual interests of the College may not be imperilled, if indeed they would not be enhanced; but are the public and the profession likely to suffer by the creation of a body of practitioners who would not be under the control of the Colleges of Physicians and Surgeons? Surely these fears are as groundless as the others, and if seriously entertained might lead to a critical inquiry as to how this control has been exercised in the past. Is it not a fact that as regards the main body of the profession the "control," such as it is, has been exercised chiefly by an authority other than the Colleges? Is it not a fact that these Colleges are hampered by ancient by-laws and restrictions as to practice which are never actually put in force? How many times in the annals of the College of Physicians have the Censors been called upon to exercise their censorial functions, and how have they responded to the call when it has been made? The College—indeed all the colleges and corporations—must look within and see how they have performed that supervision which has become little more than a name. It is a gratuitous assumption that, supposing the State granted diplomas, that the State would not exert a control quite as much for the benefit of the profession and the public as that now exerted by the Colleges. The College of Physicians in this matter has apparently linked its fate with the College of Surgeons—no doubt perceiving that the same arguments adduced in behalf of its licentiateship might be urged in favour of the surgical membership—and the resolution implies, without stating it in so many words, that the difficulties and dangers that will arise from the formation of an independent Board will be met by the establishment of a Board in which these two Colleges shall have the chief share. In other words, the College of Physicians is made to declare in favour of the Conjoint Scheme which has been so long and so fruitlessly advocated.

We have said enough to show that, in our opinion, it would have been more dignified on the part of the College of Physicians had it abstained from making an uninvited protest until the time for such protest had arrived; and its position would have been far more secure had it been contented to prove to the Commission that its licence was sought after and valued by the more highly educated members of the profession, that its examination scheme was ample and framed on an enlightened basis, and that the reasons for its having but a limited number of candidates were chiefly that its licence was not required of the holders of many public appointments. To go beyond this, and to take fright on the ground that its interests *might* be at stake *if* the Commission recommended some new scheme, was neither seemly nor politic.

The second resolution had even less justification. The uncompromising terms of the original draft were altered to an expression of opinion that the high distinction of its Fellowship is bestowed on the best possible principle in the best possible way. What reason was there for this assertion? It would almost seem as if the College felt that an attempt had been virtually made to wrest from it its most highly prized prerogative, or that it was conscious of having failed to employ it with discrimination. The resolution was certainly not politic, and in point of time unduly precipitate, for there was nothing in the circular demanding such an affirmation, and to make it unasked seems very like a defence of an ancient custom which is liable to abuse, and should therefore be endorsed by vote ere it be too late.

Happily the resolutions have lost much of their force and significance, and the College has been saved from a ridiculous position by the alteration of the original intention to send these opinions to the Commission as a reply to its secretary's letter. As instructions to their representative they may be of some service, although we do not envy him his task. He will now be able to say on full authority that the control of the College over its licentiates is salutary and well exercised; that the maintenance of the College licence is essential to medical education; that a new and independent licensing board would inflict undeserved injury upon a venerable and ancient institution; that the mode of conferring its Fellowship could not be altered without dishonour and indignity, and a lowering of the College in the eyes of the profession and the public. How far such an assertion of prerogative will forward the cause of medical education remains to be seen. Of one thing we may be quite sure—that, whatever comes, the College of Physicians will not be seriously affected; it has a future before it as illustrious as its past, and it could well have afforded to have awaited the progress of events before making declarations which at the present time are premature and unnecessary.

◆

WE recently noticed some observations of HOPPE-SEYLER on the condition of the blood in cases of extensive burns, which went to show that there is no marked destruction of, or change in, the blood-corpuscles to account for the striking general symptoms. Professor TAPPEINER of Munich has followed up these investigations by others more numerous and elaborate, from which more definite results have been obtained, to which it seems worth while to draw attention. His first observations were made on the blood and tissues of four young adult males, who died in from six to seventeen hours after burns extending over about two-thirds of the surface. In three cases a small amount, varying from ·5 per cent. to 2·5 per cent., of the total colouring matter of the blood, was found in the serum—a result in agreement with HOPPE-SEYLER'S, and confirming his conclusion. But in each case the blood was noticed to be remarkably viscid; and on estimating the amount of water, it was found to be notably deficient in relation both to the number of corpuscles and the absolute amount of hæmoglobin. Thus in one case, of 100 parts by weight, the water was found to be 70·17; in 100 parts by volume the hæmoglobin was 19·93, and the number of corpuscles in a cubic millimetre 8·96 millions. The results in the three other cases were closely similar. This condition of the blood naturally led to an estimation of the water in the tissues, in particular the muscles, when it was found that, with the exception of the first case, the amount of water was normal, 77·2 to 78·3 per cent., and in one case 75·9. There was here, then, a condition quite different from that met with in cholera, where there is a loss of water from both the blood and the muscles, which quickly leads to retention of waste products in the tissues; and TAPPEINER points out that this difference probably explains the absence of thirst, cramp, and "cutis anserina" in some cases of burns. It is not difficult to see that one source of loss of water from the blood after burns is by exudation and evaporation from the burnt surface; and, as TAPPEINER points out, inasmuch as the lack of water is observed in the blood alone, the quantity deficient is not greater than can be, and often is, lost in this manner; he indeed estimates that the loss of less than a kilogramme of water would be sufficient to produce the altered composition of the blood found to exist—a quantity quickly provided by the extensive exuding surfaces often met with. To show the extent of this exudation, he found that from the reddened burnt skin of a rabbit thick drops of fluid could always be pressed, and if the animal were placed in a temperature of 100° the fur over the burnt part remained moist, while other parts artificially moistened quickly dried. There is therefore ground for the comparison made by BUHL between the intestines in cholera and the skin in severe burns.

The question at once suggests itself why, when the blood is thus deprived of water, the tissues do not compensate its loss by yielding up their water. To this TAPPEINER gives a twofold answer. First, that the fall of blood-pressure, which is so marked a feature in severe burns, and is to some extent at least caused by the vascular dilatation in the burnt area, removes the vis a tergo from the stream flowing along the lymphatics; as soon, too, as the concentration of the blood has proceeded to any extent, it also reduces the blood-pressure, and still more retards the flow of lymph. This, however, in no way explains why the capillaries do not directly absorb water from the tissues, quite independently of any office of the absorbents proper. But if the exudation from the burnt surface be the cause of the change in the blood, it is evident that that change is not a simple loss of water. No fact in surgery is more familiar to all than that the fluid of the blisters of burns is richly fibrinous, and quickly coagulates; that indeed it is not serum, but liquor sanguinis. An exudation of liquor sanguinis does not of course alter the composition of the fluid part of the blood, but the absorption into the blood of fluid from the surrounding tissues depends upon the difference in density of the two fluids, and therefore after a burn the rate of direct absorption will not be materially altered. The conclusions deducible, therefore, are that after extensive burns so great an exudation of blood-plasma occurs from the burnt surface that the blood is concentrated, and the relative proportions of corpuscles and plasma modified even to a fatal extent; that, owing to a fall in the blood-pressure, the flow of lymph into the blood is slackened, while, the density of the liquor sanguinis not being materially altered, direct absorption of fluid through the capillary walls is not increased, and the loss of fluid is not compensated. The suggestions for treatment that naturally arise from these conclusions are the importance of means to limit exudation from the skin, and the probable value of transfusion of serous fluid in cases of burns not fatal from the first direct shock, but threatened with death from this blood change. The above facts give us a definite explanation of the circumstance that burns of the second degree affect the system far more intensely than do those of the first degree, where the impermeable cuticle is not destroyed, and they are an argument in favour of the old instruction not to remove partly detached pieces of cuticle from raw surfaces.

IT is easy to say that *insanity* means unsoundness of mind and must, therefore, include or comprise all forms of mental defect, disorder, or disease, in which the standard of health is not maintained. What is the standard of mental health by which insanity is to be recognised or gauged? It is high time that this practical question received a sober-minded answer from the collective common-sense judgment of the profession. At the present moment "insanity" would seem to be anything experts choose to make it. There is no clearly formulated ideal of sanity, and the least "strangeness" or weakness is held to be, if the general circumstances appear to render the assumption convenient, a sufficient proof of *in*sanity to deprive an individual of liberty and social privileges. A Master in Lunacy has just ruled that loss of memory is to be regarded as evidence of insanity, although, at least, *one* experienced and expert medical practitioner—not a specialist—had no hesitation in declaring that the patient, or, as we prefer to say, victim, was not insane. It may, or may not, be desirable to place persons with bad memories under the protection of the Court of Chancery. We offer no opinion on this question of policy in the domains of paternal, or what the present Home Secretary once designated "grandmotherly," government.

It is, however, intolerable that a figment of "insanity" should be set up to enable the law to protect the person and property of an individual who is simply "forgetful." We know nothing of the particular case to which this passing allusion is made, and it may happen that the Master in Lunacy was right in fact, as he must be presumed to have been in his technical judgment. It is the general consideration in respect to which we are interested. It is necessary that a protest should be raised in the name of science against the rapidly growing tendency to class every form of mind-weakness or bewilderment as "insanity." Of course incapacity may be so classed, because a mind which is not perfectly sound must needs be unsound; but this is a straining of the term, and when scientific terms are strained for legal or social purposes, it is time that science interposed to prevent what may easily come to be a great abuse.

If "insanity" is still to stand for disease of the mind, it is not expedient that it should also stand for mind weakness. The line between disease and weakness is, it must be admitted, not easy to define; but this circumstance makes it imperative that some arbitrary discrimination should be made. If there be no fixed distinction between disease and weakness, it must ever remain a matter of personal opinion whether or not any man or woman is "insane." Nothing could be more unsafe than the condition of uncertainty to which this points. For example, if loss of memory is to constitute insanity, how much or how little forgetfulness should be held sufficient to justify hurrying the subject of this common mind-trouble into an asylum? Society will surely not be content to leave the question of degree to be determined by considerations of expediency in the individual case! If the determination were so left, it might easily happen that because a wealthy man or woman forgot, or seemed likely to forget, some expectant relative in the distribution of gifts, or in the disposal of his or her property by will, the lapse of memory would be successfully pleaded as a ground for placing the offender under restraint. In short, if weakness in respect to particular mental faculties is to be classed as disease, it is indispensable that some standard or measure of the strength assumed to be *healthy* should be set up. As a matter of fact and experience, the proportion of persons in society who suffer from inability to take care of their money is very large, and if no check were put on the extravagance of such persons, they would be ruined; but it has not yet been deemed desirable to treat spendthrifts as lunatics, although doubtless the majority might be held to fall under that description. The mental counterparts of myopia and colour-blindness, and a multitude of sensory defects and disorders, are recognised. Already we have agaraphobia, and claustrophobia, and gynephobia, and a host of recent additions to the long catalogue of mental disease, loss of memory being duly registered among the number; but hitherto it has been deemed proper to establish the fact of insanity by some obvious and strongly-marked feature of the disease *before* defining the technical peculiarity of its special manifestation. If this safe, though perhaps old-fashioned, method of proceeding is to be abandoned, the reasons for the change should be clearly set forth and generally understood. In respect to the question of scientific expediency, the profession, as a whole, must be the judge, not that limited section of the medical body which lays claim to a special knowledge of mental disease. At least we have the right to know what is going on, even though we may be held incompetent to understand it.

In the days of professional ignorance—before the advanced light of modern thought had discovered the fact that insanity is *in*curable—there was a general agreement that no one should be classed as a lunatic and declared insane unless he was the victim of a delusion likely to be dangerous to himself or others. At that time, no doubt, asylums were houses of terror, and especial pains were needed to save the victims of mind-weakness from incarceration. No humane person would then have thought of consigning a man to the tender mercies of the keeper of a madhouse because he entertained a belief that it was wrong to use the skins or wool of animals as material for clothing! The lunatic asylum of to-day is, however, a pleasant place to live in, and the definitions of insanity have been so extended as to include many forms of derangement which our fathers and grandsires would not have dreamt of so classing. This is one of the disadvantages of the improved system of treatment for the insane, and society must put up with it. Nevertheless, in the interests of common sense, if not of humanity, we must invent some new term for the designation of genuine and actual insanity, if all the pretended and imaginary forms of mind-weakness which the ingenuity of specialism can devise are to be comprised under the old term as occasion may seem to render desirable. We say nothing against the policy of placing half the population under the surveillance of the other half, though it may be difficult to determine which should be the keepers and which those kept, but we do protest against playing fast and loose with terms which still retain, or are supposed to retain, a modicum of scientific significance.

IN another column will be found a letter from a correspondent in the Isle of Wight protesting against our observations on Dr. BALLARD'S report on the sanitary condition and administration of the island, so far as the district in which he is interested (Ventnor) is concerned. He sends us also a copy of a report of a committee of the sanitary authority which shows that in Ventnor, at least, Dr. BALLARD'S report has been properly appreciated, his recommendations being duly acted upon. The Ventnor Sanitary Authority has clearly set an example which only needs to be followed by other sanitary authorities in the island to quickly dispel the very unfavourable impression made by Dr. BALLARD'S report, and to rehabilitate the place in the opinion of invalids and tourists as foremost among English health resorts. It rests, indeed, with the local authorities of the island themselves whether the Isle of Wight shall continue to hold the pre-eminent position as a health resort which it has hitherto occupied from its topographical position, or whether, from the suicidal policy which has characterised its sanitary authorities and their administration, this year will mark the beginning of a regrettable decline in its reputation as a wholesome place to dwell in, even temporarily. The example of Ventnor gives reason to hope that the different sanitary authorities will not hesitate to take active measures for removing the various evils brought to light by Dr. BALLARD. We shall warmly welcome news that the good sense displayed by Ventnor is not confined to the sanitary authority of that district in the island. The subject of the health condition of the Isle concerns, and that very largely, others besides the inhabitants; and nothing will tend so quickly to restore confidence among outsiders as a knowledge of the fact that the several sanitary authorities have set themselves loyally, after the fashion of Ventnor, to place the health conditions of their respective districts in such a position as even Dr. BALLARD would be constrained to approve.

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS.

DURING the ensuing official year the Royal College of Surgeons will occupy a position of unusual prominence and importance. At the International Medical Congress the President and Council of the College will be the recognised representatives of English surgery. Before the Congress meets the term of office of the present distinguished occupant of the presidential chair of the College will have expired, and unless the members of the Council have the courage and good sense either to re-elect Mr. Erichsen or to depart from the customary routine of electing the senior vice-president to the presidential chair, the Royal College of Surgeons of England will, at the International Medical Congress, have for its reputed head a gentleman who, notwithstanding his renown as a dermatologist cannot be regarded as in any intelligible sense a representative English surgeon. With such eminent surgeons on the Council as Mr. Erichsen, Sir James Paget, Mr. John Marshall, Mr. Savory, Mr. Hutchinson, and Mr. Lister, it would be both anomalous and unseemly for the College to choose for its president during the meeting of the International Medical Congress a gentleman whose professional reputation is simply that of a dermatologist. The duty of electing the president is entrusted by charter to the Council itself, and it is incumbent upon the members of the Council in electing the next president to show a proper discrimination between their peculiar tastes, and interests as a social body, and their larger responsibilities as the representatives of English surgery, and the guardians of the honour and dignity of the ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A ROYAL RECOGNITION OF HEROISM IN MEDICINE.

WE learn that the Queen has been graciously pleased to confer the decoration of the "Albert Medal" of the First Class (for gallantry in saving life) upon David Lowson, M.D., of Huddersfield, under the following circumstances:—On the 12th November, 1880, Dr. Lowson was called to attend the child of Police Constable Higginbottom, of Huddersfield, who was suffering from laryngeal diphtheria. He performed the operation of tracheotomy, but suffocative attacks supervened, and on visiting the child next morning he found it in a livid state and breathing only with great difficulty. Seeing that the only chance of saving the child's life lay in sucking the tube clear, he at once, at imminent risk to himself, applied his lips to the tube and sucked out the accumulated mucus, thereby affording immediate relief to the patient. Throughout the day he continued, by means of a pipette, to suck out the mucus from the trachea. Notwithstanding his efforts the child unfortunately died on the third day after the operation. Dr. Lowson's heroism was following by a severe attack of diphtheria, with which he was seized in the course of a few days. Other dangerous illness supervened, compelling him eventually to abandon his profession and to retire from a lucrative partnership. We are much gratified at being able to give our readers particulars of an act, on the part of Her Majesty, which will be deeply appreciated by the medical profession. Such gracious recognitions on her part cannot, in the nature of the case, be very frequent, for the simple reason that such conduct as Dr. Lowson's is, in its principle at least, a matter of not infrequent occurrence. But it is satisfactory to know that deeds of daring done by medical men in quiet sick rooms for the chance of saving life—in this instance a child's life—and in entire disregard of risk, are not overlooked by one whose character and station give to her approval a great value. A plucky deed on the battlefield may have its reward in the enthusiastic plaudits of bystanders, or in the fame which accrues from report and public comment, but the silent courage implied in such an act as Dr. Lowson's is apt to go unreported and unrewarded, except in the consciousness of him who does it.

INTRA-PERITONEAL TRANSFUSION.

THE grave results which often follow the escape of blood into the peritoneal cavity would scarcely lead to the anticipation that it would be found a suitable site for the transfusion of blood. Nevertheless, it has been shown to be such by Ponfick, and several cases in which intra-peritoneal transfusion has been employed have been recently published by Kaczorowski. The injection of the blood is by a trocar introduced through the linea alba, the blood being poured through a glass funnel furnished with a flexible looped tube. The operation is performed under strict antiseptic precautions, and the admission of a little pure air into the peritoneal cavity appears to be harmless. The method is recommended especially in prolonged febrile diseases, in which the heart's action fails, and also in chronic anæmic diseases. The reaction of the serous membrane is said to be slight, and often *nil*. Of the cases recorded, one was a female twenty-one years of age suffering from puerperal septicæmia; two transfusions were made, each of 500 grammes of defibrinated blood; the patient recovered. The second patient was suffering from anæmia, hysteria, and spinal irritation, and recovered after a single transfusion. The third case was one of phthisis, and the patient was improved by the operation, but died three months later. The fourth was that of a woman fifty years of age, very anæmic and depressed, with fungous ulcers in the neck; after the latter had healed there was no improvement in the general condition, but convalescence rapidly set in after the transfusion of 600 grammes of blood. The last patient was a drunkard, forty years of age, suffering from a severe attack of exanthematic typhus, with bedsores. After the transfusion of 400 grammes of blood the fever lessened, the other symptoms improved, and the patient recovered.

THE INTERNATIONAL MEDICAL CONGRESS.

A MEETING of the General Council of the Congress was held at the College of Physicians, Pall-mall, on Wednesday, June 22nd, under the presidency of Sir William Jenner. The report of the Executive and balance-sheet were read and adopted. It was stated that Sir Wm. Jenner would take the chair at the opening meeting of the Congress until the officers are duly elected. His Royal Highness the Prince of Wales has intimated his intention of attending this meeting. A cordial vote of thanks to Mr. MacCormac for his untiring energy was carried by acclamation on the proposal of Professor Acland. Mr. Bowman, in reference to the Treasurer's report, urged the desirability of making the subscription list as wide as possible. We are requested to state that, in addition to the excursions noted last week, the Members of the International Congress are invited to visit the Croydon Sewage Farm, and afterwards inspect the Beddington Female Orphan Asylum, where lunch will be provided. Those desirous of going should intimate their wish to Dr. Alfred Carpenter of Croydon, as soon as possible

"STATE-REGULATION OF VICE."

IT should occasion no surprise that confederations to abolish, or prevent, any sort of interference on the part of the State having for its object to minimise the evils contingent on vice, flourish here and on the Continent. Nor is it strange that excellent, well-intentioned, and even sagacious persons are found in the ranks of the agitators. It is one of the characteristics of modern thought, and would seem to be a striking trait of the most recent development of intense humanitarianism, that the pursuit of the highest good for the greatest number is peculiarly apt to be accompanied with intolerance of the needs of special classes of the community. It is nothing to the impulsive reformer that human nature is, and always will be, so constituted that it must needs be saved from the consequences of its own wrong-doing. These optimist moralists will hear of no concession to weakness, and spurn the thought of conceding anything to the exigencies of our imperfect state. They would not have given so much as a cup of cold water to either of the impenitent thieves, and would have shrunk with horror from the prayer of the devils that they might pass into a herd of swine. Hagar might have perished with her ill-gotten babe in the wilderness, Jonah would have been left to die in the sun, and the manslayer might have been overtaken by the avenger, before one of the agitators against Contagious Diseases Acts, or any other provision for lightening the so-called "penalties of sin," would have striven to help them. The argument would have been, these thieves deserve their punishment, and it will encourage others if we relieve their sufferings. These evil spirits have no claim to our compassion; and we must, for example's sake, turn a deaf ear to their beseechings. If such characters as Hagar are relieved, and the children of their shame rescued from destitution, vice will be fostered. Those who take life must pay the penalty; it will increase the crime to reduce the punishment; even the disobedience of a prophet must be visited with its due recompense. This is precisely how the agitators argue against the Contagious Diseases Acts, against foundling asylums, and other measures to reduce the contingent social and personal effects and penalties of vice. It is no use trying to convince those who can find satisfaction in such reasoning. We are not disposed to prolong the struggle against this movement; our appeal must henceforth be to the common sense of the community. The infatuated few, who think they are doing good service by a crusade against measures for the relief of the sinful and their victims, must be left to their own devices, and hereafter to their own reflections. The spectacle of such a gathering, and so much wasted zeal, as London has witnessed during the last few days, is humiliating; but not more so than many similar manifestations of misguided philanthropy. It is part of the price society has to pay for its advanced civilisation.

DR. BROWN-SÉQUARD'S EXPERIMENTS.

DR. BROWN-SÉQUARD is pursuing vigorously his remarkable investigations into the effect on the central nervous system of peripheral applications. A continuation of his researches was communicated to the Société de Biologie at the meeting on the 11th inst. The experiments first described were on the inhibitory and "dynamogenetic" action of applications of prussic acid. When this has been injected into the neck or limb, near the brachial or cervical plexus, it produces exophthalmos, limited more or less perfectly to one eye, a rosy tint of the blood in the vessels of one side, and also certain other unilateral symptoms. Hence, he assumes, when the excitability of the nerves and muscles is rapidly lost in consequence of the administration of a large dose of the acid, this loss is not due to a direct action, chemical or other, on the nervous and muscular tissues, but chiefly, if not entirely, to an inhibitory influence exerted by the central nervous system under the irritation of the poison. The proof of this is afforded by certain cases in which the poison has been injected under the skin after the phrenic or sciatic nerves have been divided. The divided nerves and their muscles remain excitable two, three, or four times as long as in animals dying of simple asphyxia under similar conditions. If the poison is injected and the nerves are not divided, the duration of their excitability is much less than in simple asphyxia. This may be demonstrated by the section of the phrenic nerve on one side only. Clearly, then, the inhibitory influence produced by prussic acid must descend the nerve from the centre. The same influence may produce the opposite effect, an increase of irritability, shown by its persistence in the divided nerves for a much longer time than in the case of an animal dying of simple asphyxia. It will be remembered that earlier experiments demonstrated that chloroform and anhydrous chloral applied to the skin of the thorax on one side had a dynamogenetic action on the phrenic nerve and diaphragm of the same side, and an inhibitory action on the opposite side. The same effect is often produced by the injection of prussic acid, or of some other violent poison, such as pure digitaline, under the skin of the thorax or into the axillary fold; and digitaline has a similar effect upon the limbs. The most striking dynamogenetic effects have been obtained by section of one-half of the base of the brain or of the spinal cord. An increase of irritability may be found usually on the same side, in the nerves of the brachial plexus, the phrenic, or the sciatic. But there is a curious alternation in the effect. If, for instance, the right phrenic nerve is rendered more irripersed in the Transactions of the Royal, Linnæan, and Zoological Societies, in the *Journal of Anatomy and Physiology*, in the Archæologia, and in the journals of the Geographical Society, the Odontological Society, and the British Association tell the same tale. Whether they, with many other printed documents and lectures, should be collected and published as a monument to his memory, is a matter for scientific men and his friends to determine. He was a sound and accurate scholar as well as a scientific man, and has been heard to say that his father had tutored him so thoroughly in Greek that he was able at ten years of age to read any part of Homer at sight, and at a later period was so familiar with that language that he could think in it. He took great interest in social questions of all kinds. He was popular with the promoters of the temperance cause, and was an earnest advocate of the Permissive Bill. In politics he was a Liberal. But though he had many interests, he devoted his life mainly to the advancement of biological science. When he came to Oxford as a young physician he undertook the readership in anatomy as but a secondary occupation in addition to medical practice, but in entering upon his duties as keeper of the anatomical and physiological collections in the Christchurch Museum his views of biological science expanded. For several years previous to this, assisted by Dr. Victor Carus, Dr. Melville and Mr. (now Professor) Beale, Dr. Acland had endeavoured to give an impulse to practical philosophical biological work as a part of general education in the old Universities, taking the Hunterian Collection as a model on which to base and develop this plan. Dr. Rolleston took up this great question, and when the Linacre Professorship was founded was chosen by the electors to fill it, though then a comparatively unknown youth. He at once relinquished practice. The Oxford Museum, now so well known, was then just completed. The Dean and Chapter of Christchurch decided to allow the anatomical collection under Dr. Rolleston's care to be moved, for university rather than the narrower collegiate purposes, to the new institution. It was then hoped and believed that this institution would gradually extend until it was able to exhibit and advance every scientific department in the most perfect manner. The Radcliffe trustees, in the same hope, transferred their scientific library to the museum. The young anatomist found his biological series and all the workrooms that had been provided for him in close proximity to the palæontological collections of Buckland, the departments of physics and chemistry and the literature of all these allied sciences. From that moment his mind was turned without ceasing to the contemplation, the practical study, and illustration of man as man by every possible method; his descent, his development, his relation to other beings, their relation to each other, and to the organic world. Every department of anatomy, however minute, of physiology, however abstruse, and of ethnology, however complex, from time to time yielded a store of material to his vigorous grasp. Every line of research, from those of Prichard, Max Müller, or Darwin, to those of Lister or Parker, seemed in turn to be taken up. It so happened that in 1860 a circumstance occurred which tended materially to concentrate all the qualities of his nature on the highest biological questions, whether considered from the material or psychological point of view. The British Association met in Oxford, and the famous discussion on the hippocampus in the brain of man as compared with that of the higher apes took place between Professors Owen and Huxley. Bishop Wilberforce brought, as is well remembered by all scientific men, the forces of his ready wit and great reputation to bear against the sincere statements of the younger anatomist. Rolleston's indignation was fired; his sense of justice made him throw heart as well as head into the cause of what, at the moment, seemed the weaker man. It is not possible to say now to what extent that brief scene influenced the ardour and imagination of Rolleston. Be this as it may, all prejudice and even bias derived from the most refined Oxford culture was banished from his mind in dealing with the nature of man. Oxford has the greatest cause to recognise and to remember Dr. Rolleston's character as a teacher. He has many devoted pupils, gradually finding their way to posts of trust in various scientific institutions and hospitals in London and elsewhere. He taught all who were capable of being taught to work with great and comprehensive aims even while engaged in small and laborious details. And with his teaching he instilled also a sense of duty. Especially has this been felt by those of his pupils who have since become teachers. Among the rewards of his labours the one, perhaps, which he most highly appreciated was when his friends or pupils from various parts became contributors towards the completion of his anatomical collections. Warm-hearted, impetuous, with wide sympathies and generous impulses, Rolleston was a delightful companion, an entertaining and a liberal host, and a constant friend. He was a most energetic worker, rising and being often in the museum at 5 A.M., so that he was accustomed to say that between Professor Clifton, whose delicate experiments required the quietude of the night, and himself, the museum was rarely untenanted for an hour. Of him it might truly be said that when, in Oxford, a scholar or a physiologist was the theme his name was not far off.

Dr. Rolleston's health had long been a cause of anxiety to those who were intimate with him. He had shown for two or three years an over-sensitive condition of the nervous system. There had been noticed great and rapid variations in the circulation under excitement, and he had long suspected changes in the arterioles of the brain. In the course of last autumn albumen was first noticed in the urine without casts, and considerable cardiac hypertrophy.

From that time his health began rapidly to decline. He accompanied Sir William Gull and Dr. Acland to Florence in December, to remain on the Riviera for some months. A few weeks before his death anasarca of the lower limbs began, with extreme general malaise. In the last days there were constant convulsions, so that the end was a release from distress which was hard to bear but was borne with gentleness and patience. In Paris he was under the care of Dr. the Hon. Alan Herbert, and Professor Charcot, and was at his earnest desire removed to England, though with difficulty. Dr. Child joined him at Paris, and returned home with him, Dr. Herbert having come with him as far as Boulogne.

Dr. Rolleston married Grace Davy, niece of Sir Humphry Davy, and grand-daughter of Mrs. Fletcher of Grasmere, by whom he leaves a numerous family, none of whom are yet grown up. Mrs. Rolleston lies gravely ill in the house where her husband died. She is in an unconscious state, and is still ignorant of her loss.

Immediately after the funeral a meeting of Prof. Rolleston's old pupils was held in the Museum, with the object of perpetuating his name by some suitable memorial. A committee was formed with power to add to its number, the following gentlemen being elected honorary secretaries: Dr. C. Mansell-Moullin, 17, George-street, Hanover-square, W.; Dr. Theodore Acland, St. Thomas's Hospital, S.E.; Mr. E. B. Poulton, M.A., Wykeham House; and Mr. A. P. Thomas, M.A., Anatomical Department, Museum, Oxford.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Tuesday, Earl Spencer presented petitions from the Liverpool Veterinary Medical Association in favour of the Veterinary Surgeons Bill; also from various persons in Kent and Sussex, being veterinary surgeons in England who are not members of the Royal College of Veterinary Surgeons, against the Bill.

In the House of Commons on Thursday, the 16th inst., the report and evidence of the committee on the position of the medical officers of the navy were presented. On the motion of Mr. Courtney, amended returns were presented relating to convictions under the Vaccination Acts, and on the motion of Mr. H. H. Fowler a return was ordered of the small-pox hospitals in the metropolis. The Blind and Deaf Mute Children Bill was withdrawn.

Treatment of Prisoners in India.

On Friday, Mr. O'Donnell gave notice of the following questions:—To ask the Secretary of State for India if he is aware that the mortality among prisoners in gaol in India averages annually, at present, from 250 per thousand to 390 per thousand; whether he is aware that this fearful mortality is alleged to be mainly due to starvation on the prison diet; whether it is true that 8223 prisoners have been flogged during the year for non-performance of allotted work; whether his attention has been called to statements in the *Bombay Gazette*, *Calcutta Englishman*, and other Indian papers, that "prisoners who, from want of food, were unfit to labour, were dragged to the triangles and flogged by the thousand because they were weak and sick unto death on starvation rations;" and, if these allegations be true, why he has not interfered.

Mr. Gray gave notice that he would move to discharge the order for going into Committee on the Infectious Diseases Notification (Ireland) Bill, and to withdraw the Bill, which it is proposed to refer to a Select Committee.

Fees to Medical Officers.

On Monday, Mr. T. Rogers asked the President of the Local Government Board whether, since the scale of fees payable to the medical officers of Poor-law Unions was furnished many years ago by the Poor-law Board, he would consider the desirability of its revision, especially in relation to those operations for which, as medical science had progressed, the use of anæsthetics was necessary, and therefore the services of an assistant operator were required; and if he would further consider how far, in the absence of any provision for the payment of such assistant operators, the sufferings of the poor, who were constrained to undergo operations, might remain unalleviated or be increased.—Mr. Dodson said he would not fail to consider whether it was desirable to revise the scale of fees payable to the medical officers of Poor-law Unions, especially in cases where the use of anæsthetics was required. At the same time he would remind the hon. member that the policy of the Poor-law Administration had been not to encourage the performance of difficult operations by Poor-law officers, but rather to induce the removal of such cases to the public hospitals, where they might be properly and skilfully treated.

Overworking Telegraph Clerks.

Mr. Fawcett, replying to Lord R. Churchill, gave particulars of the case of a telegraph clerk who was alleged to have become temporarily mentally deranged from overwork. During the week previous to his illness he worked nine hours and twelve hours on alternate days; but during another week prior to that his work only occupied three hours a day. The new regulations would give important relief from excessive overtime. In this particular case the man had always been in delicate health, but as his absence would be only temporary full pay would be allowed him during that absence.

Militia Surgeons.

Dr. Farquharson gave notice that he would on Friday ask the Secretary of State for War whether it is his intention to grant compensation for loss of expectation of pension to those Militia surgeons who joined previous to Lord Panmure's Circular of 1854, and whether it is his intention to compensate Militia surgeons generally for the serious loss of income inflicted on them by recent changes, and in particular by the withdrawal of fees for the examination of recruits.

On Tuesday, the annual report on Irish Lunatic Asylums was presented. The Coroners (Ireland) Bill was considered in Committee. Mr. Corbet gave notice of a question as to the removal to an Irish asylum of an Irish lunatic soldier, enlisted in England. Mr. Sclater-Booth gave notice of a question as to the superannuation of Poor-law officers. Mr. O'Sullivan will on Friday ask whether one of the Kilmainham prisoners is not losing his sight in consequence of his long confinement in prison. Mr. Healey will on the same day put a question as to the appointment of non-qualified veterinary inspectors at Irish ports.

Vaccination.

Mr. P. A. Taylor gave notice of a question for Tuesday, as to the death of a child at Plymouth "from exhaustion, indirectly due to vaccination." The same hon. member will move the following amendment to Dr. Cameron's resolution on Friday, July 8th:—"That in the opinion of this House, the frequent recurrence of small-pox epidemics in London, in the midst of a very generally vaccinated population, raises grave doubts of the efficacy of vaccination as a protection against small-pox, and when to this is added the acknowledged danger of transmitting disease by the process, compulsion at any rate can no longer be defended."

On Wednesday, various petitions for or against the Rivers Conservancy and Floods Prevention Bill were presented, and referred to the Select Committee on the Bill.—Mr. Gray moved to discharge the order for going into Committee on the Infectious Diseases Notification (Ireland) Bill, with a view to withdrawing the Bill pending its consideration by a Select Committee; but Dr. Lyons objected, and the order was deferred.—Mr. O'Shaughnessy deferred to Monday next his question as to the maintenance of Irish lunatics.

On Thursday, Mr. Childers replied to Mr. Corbet that an insane Irish soldier, named Wheelan, had been removed to an Irish workhouse where he applied to be chargeable, and his pension would be credited to the union.

London Fish Supply.

In reply to Mr. Firth, Sir William Harcourt said he had received a notice from the Corporation, stating that a committee would be appointed to inquire into the present unsatisfactory state of the fish supply of the metropolis. He should say, however, that considering how long this question had been in the stage of inquiry, the time has come when something should be done. He hoped that Billingsgate market would be improved. He could not see any reason why the supply of this essential article of food should be a monopoly in the hands of one authority. He thought that the Metropolitan Board of Works, which had accomplished such great and useful work in the metropolis, might well take up the subject.

The Removal of Dust.

In answer to Viscount Newport, Mr. Dodson said the Local Government Board had no jurisdiction over the metropolitan vestries with regard to their dust-carts. He was afraid, therefore, he could not undertake with any advantage to communicate with them on the subject. At the same time he ventured to hope that as the attention of the vestries had been called to the subject by the question of the noble lord, they would be disposed to take the matter into consideration.

Fees for Medical Operations.

In reply to Mr. Firth, Mr. Dodson said his attention had been drawn to the case of Mr. Hele, district medical officer of Plomesgate Union, who, in obedience to an overseer's order, attended a boy for injury and amputated his leg. With the imperfect information before the Board, he was not prepared to express any opinion upon the point, whether the medical officer in question was entitled to perform the operation. With regard to the question of the payment of the fee, it did not appear that the time in which proceedings could be taken had yet expired. Whether the time in which to test the legality of the action of the Guardians should be extended depended in the first instance upon the determination of the question whether the claim was legal. In the present state of the correspondence he could not undertake to lay a copy on the table of the House, but he was not aware of any objection to doing so as soon as it was convenient.

Emigrant Ships.

In reply to Mr. Moore, Mr. Chamberlain said, on the 30th May he stated very fully the course the Board of Trade had taken with regard to the treatment of steerage passengers in emigrant ships. Papers on the subject would be in the hands of members in a few days.—Mr. T. P. O'Connor asked if he was to understand that no further steps would be taken to secure decency and morality on board the ships. He had had communications calling attention to the condition of steerage passengers.—Mr. Chamberlain said that the honourable member would find the matter was fully investigated in the papers, and recommendations therein made. He should be glad to receive any special information on the subject.

Treatment of Prisoners in Bengal.

The Marquis of Hartington, in reply to Mr. O'Donnell, said the excessive mortality in certain prisons appeared to be due partly to the fact that prisoners in weak health were put there from other gaols for treatment, and partly to the establishment of a new prison diet, which was found to be insufficient, and was subsequently changed. It was true that the number of persons mentioned in the question had been flogged, but the Lieut.-Governor had been communicated with on the subject by the Indian Government, and since then there had been a marked diminution in the number of floggings. The substitution of some form of penal labour for corporal punishment was now being considered, it being proposed to reserve flogging for the most serious cases. There was much exaggeration in the newspapers, but he regretted to say there was some foundation for the statements made. Inquiry was being made on the subject.

Medical News.

UNIVERSITY OF OXFORD. — The following gentlemen passed the Final Examination for the degree of M.B.:—

Falls, W. C., B.A., M.R.C.S., Merton College and St. George's Hosp.
Francis, F., B.A., M.R.C.S., Jesus College and London Hospital.
Gresswell, D. A., B.A., M.R.C.S., Christ Church and St. Bartholomew's Hospital.
Jones, Wansborough, B.A., M.R.C.S., Magdalen College and St. Thomas's Hospital.

UNIVERSITY OF CAMBRIDGE. — The following degrees were conferred on June 16th:—

DOCTORS OF MEDICINE. — Arthur Thomas Myers, Trinity; Francis Henry Hill Guillemard, Caius.
BACHELORS OF MEDICINE.—Fredk. Henry Horatio Mahomed, Caius; Charles Fillingham Coxwell, Christ's.

APOTHECARIES' HALL. —The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 16th:—

Sukhia, Jehangir Cursitji, Arlingford-road, Brixton.
Trapp, John Best, Wellfield House, Bedford.

The following gentleman also on the same day passed the Primary Professional Examination:—

Newsholme, Henry Wilkinson, University College.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. Runcy, late of Aberdeen, bequeathed to the Royal Infirmary £500, with a contingent residue of the estate to the Infirmary and to the Dispensary of the town. The Tunbridge Wells Infirmary receives £100 under the will of the late Mr. Samuel Hindley. Mr. Wm. Riches bequeathed £50 to the Clapham Dispensary.

THE WARREN TRIENNIAL PRIZE.—The Warren Prize Committee offer a premium of 400 dollars for the best Dissertation worthy of a prize, upon the following subject:—"Chronic Bright's Disease (Parenchymatous and Interstitial Nephritis). The Nature and Mutual Relations of the Derangements in the Circulatory and Secretory Organs." Dissertations should be forwarded to the resident physician, Massachusetts General Hospital, Boston, on or before February 1st, 1883.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The new wing of this hospital was formally opened on Wednesday by the Princess Christian of Schleswig-Holstein. Erected at a cost of about £9000, this recent annexe is in reality the initial instalment of a scheme of total rebuilding, intended to replace the overcrowded and inconvenient rooms hitherto in use, and, in fact, to supply a new hospital worthy of the country. After the ceremony, which was attended by a large and distinguished company, the Princess inspected the upper floor of the new building. In the evening an entertainment was given in the new waiting hall.

ST. THOMAS'S HOSPITAL.—On Tuesday the prizes were distributed to the successful students of this hospital by the Earl of Dunraven, who, in the course of his address, urged, as did the Bishop of Gloucester and Bristol last week in the medical school of the latter city, the cultivation by the students of a broad and liberal spirit in the pursuit of their studies. The Mead Medal for Practical Medicine, under Dr. Stone, was awarded to W. Wansborough Jones, of Leek, who also received the Treasurer's Gold Medal for "general proficiency and good conduct." W. Haig Brown of Godalming, received the Cheselden Medal for surgery and surgical anatomy. A. B. Bernays of Stanmore, A. D. Roe, and W. J. Sheppard received the college prizes of £20, £15, and £10 for third year students. W. B. Tomson of Luton, who was a winner of a first-year student prize, received the Musgrove schlolarship of forty guineas and certificate of honour, as a second-year student and a prize as a prosector. G. D. Green of New-cross, received the College prize of £20 and certificate of honour, and F. F. Caiger £10 and a like certificate, as second-year students. R. Lawson of Winthank, North Britain, received the great prize of the year, the entrance science scholarship of £100 and a certificate of honour, also the Wm. Tite scholarship of £30 as the best in first year's studentship. W. H. Lancaster of Leicester, was second in both these classes, receiving a £60 scholarship and the College prize of £20, with certificates of honour. The other winners of prizes were F. W. Hatchett of Neath; R. E. Rouse of Woodbridge; G. A. Carpenter of Lambeth; and G. W. Ford of the Cape of Good Hope.

THE LEVEE.—The following members of the medical profession were presented at the levée held on Wednesday last at St. James's Palace by the Prince of Wales, by command of Her Majesty:—Surgeon-General Sir J. Campbell Brown, K.C.B., Acting Surgeon C. F. Bryan, Surgeon-Major W. E. Cates, Surgeon R. F. Cumming, Surgeon W. Coleman, Surgeon L. O'B. Curtin, Surgeon J. H. Earle, Acting Surgeon W. A. Ellis, Surgeon E. H. Fenn, Surgeon-Major J. F. Fitzpatrick, Dr. W. H. Hart, Surgeon R. C. Johnston, Surgeon T. R. Pickthorn, Surgeon C. Reid, Surgeon S. Westcott. The following attended the levée:—Dr. Watt Reid, Dr. Farquharson, Dr. Ralph Gooding, Dr. Playfair, and Mr. James Startin.

Births, Marriages, and Deaths.

BIRTHS.

DUKE.—On the 20th inst., at The Glen, Lewisham, the wife of John C. Duke, M.R.C.S.E., of a son.

GARDINER.—On the 20th inst., at 13, Harlington-gardens, Edinburgh, the wife of T. Senior Gardiner, of a son.

MILLER.—On the 16th inst., at Trinity-place, Windsor, the wife of Richard Shalders Miller, M.B., B.S., F.R.C.S.E., of a daughter.

POWER.—On the 14th ult., at Kasanli, East India, the wife of Surgeon-Major R. Power, 11th Prince of Wales's Own Bengal Lancers, of a daughter.

PRINGLE.—On the 14th inst., at Angelton, Bridgend, the wife of H. T. Pringle, M.D., Medical Superintendent of the Glamorgan County Asylum, of a daughter.

SMITH.—On the 18th inst., at Charles-street, Berkeley-square, the wife of Barton Smith, M.D., of a daughter.

YOUNG.—On the 11th inst., at Follett House, Devonshire, the wife of David Young, M.D., Florence, of a daughter.

MARRIAGES.

CHAMBERS—COLLARD.—On the 15th inst., at Trinity Church, Broadstairs, by the Rev. G. F. E. Shaw (godfather of the bride), assisted by the Rev. J. H. Carr, Rector of Broadstairs, Eber Chambers, M.B., of 9, Wilmington-square, London, to Annie Laurie, fourth daughter of Thomas White Collard, Esq., of The Limes, Broadstairs.

EYRE—BRIGHT.—On the 15th inst., at Christ Church, Forest-hill, John Joseph Eyre, L.K.Q.C.P.I., L.R.C.S.I., eldest son of Edmond Eyre, Esq., of Shanagolden, Limerick, to Fanny Amy Agnes, eldest daughter of John Meaburn Bright, M.D., of The Glen, Westbourne-road, Forest-hill.

GARDNER—LINTON.—On the 13th inst., at St. Mark's, South Norwood, by the Rev. W. G. Longden, M.A., Vicar, John Twiname Gardner, L.R.C.P.L., M.R.C.S.E., L.S.A.L., of Ilfracombe, Devon, to Kate, youngest daughter of the late W. J. Linton, of South Norwood. No cards.

HARRIS—UPTON.—On the 4th inst., at St. Marylebone Church, London, Benjamin Harris, M.R.C.S.E., third son of the late William Harris, of Park-street, Grosvenor-square, to Mary Anne, second daughter of William Upton, of Woodfield, Upper Norwood, Surrey.

KNOX—THOMPSON.—On the 16th inst., at St. Catherine's Church, Birkenhead, by the Rev. Andrew Knox, M.A., LL.D. (brother of the bridegroom), assisted by the Rev. M. L. J. Mortimer, M.A., Vicar of the Parish, Charles Knox, M.R.C.S.E., L.K.Q.C.P.I., of Bay House, Tranmere, Birkenhead, to Emily Kate, second daughter of Robert Thomson, Esq., of Claremont, Claughton, Birkenhead.

LE QUESNE—LE QUESNE.—On the 1st inst., at the Parish Church, St. Helier's, Jersey, Edwin Joseph Le Quesne, L.R.C.P.L., M.R.C.S.E., of Tring, Herts, to Mary Ann Alice, daughter of W. Le Quesne, Esq., of Balmoral-terrace, Jersey.

NICHOLSON—EDGER.—On the 18th inst., at St. Pancras Registry Office (the civil to be followed by the religious ceremony at the Church of Humanity), Surgeon-Major Edward Nicholson, Army Medical Department, to Sophie Clotilde, third daughter of Henry and the late Millicent Edger, and adopted niece of Dr. and Mrs. Congreve, of Mecklenburgh-square.

WOODMAN—NORRIS.—On the 18th inst., at St. Paul's Church, Tottenham, William Robert Woodman, M.D., of Ford House, Exeter, to Mary, widow of William Lascelles Norris, M.R.C.S.E., and daughter of the late George Garland, Solicitor, of Worcester and Malvern.

DEATHS.

BLOXHAM.—On the 8th inst., at Halesowen, Charles William Milnes Bloxham, M.R.C.S.E., aged 59.

CRISP.—On the 14th inst., at Aix-les-Bains, Savoy, from the result of an accident, Walter Crisp, Surgeon-Major, Army Medical Department, aged 52.

GAWTHORPE.—At Ventnor, Matthew Gawthorpe, L.S.A.L., aged 77.

MUSGRAVE.—On the 21st ult., at Bombay, of heat apoplexy, Reginald Vernon Musgrave, M.R.C.S.E., Surgeon of the P. and O. Co.'s Service, aged 31.

NUTTALL.—On the 21st ult., at San Francisco, California, Robert Kennedy Nuttall, Esq., M.D., F.R.C.S.I., youngest son of the late Colonel J. C. Nuttall, J.P., of Tittour, co. Wicklow, Ireland, aged 66.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths*

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

Anderson, W., F.R.C.S., has been appointed Joint Lecturer on Anatomy at St. Thomas's Hospital.

Barker, H. M., M.B., F.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Brading District of the Isle of Wight Union.

Berry, F. C., M.B., B.Ch., has been appointed Medical Officer for the Eleventh District of the Barnstaple Union.

Burton, R. G., M.D., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the Hanwell Rural Sanitary District.

Corry, W., M.D., M.Ch., has been appointed Medical Officer to the Drumquin Dispensary District, vice Johnston, deceased.

Currie, J. L., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Earsham District of the Depwade Union.

Dalton, N., M.B., has been appointed House-Surgeon to the North-Eastern Hospital for Children, vice Steele, resigned.

Ewen, A. B., M.R.C.S.E., L.S.A.L., L.M., has been appointed Surgeon to the Exmouth Dispensary, vice G. W. Turnbull, resigned.

Foster, H., M.R.C.S.E., has been appointed Medical Officer for the Green Hammerton District of the Great Ouseburn Union.

Harris, F. W. H. D., M.R.C.S.E., has been appointed Medical Officer to the Teignmouth, Dawlish, and Newtown Infirmary, vice Taylor, resigned.

Harris, J. D., M.R.C S.E., L.S.A.L., has been elected Surgeon to the Devon and Exeter Hospital, vice C. H. Roper, deceased.

Henderson, G. C., M.B., M.R.C.P.L., M.R.C.S E., has been appointed Curator and Pathologist to St. Mary's Hospital, vice Pepper, resigned.

Hodgson, G. F., M.R.C.S.E., has been appointed Honorary Surgeon to the Brighton, Hove, and Sussex Throat and Ear Dispensary.

O'Donovan, E., L.R.C.S.I., has been appointed Medical Officer for the Knocknalower Dispensary District.

O'Keefe, W. J., L.R.C.S.I., has been appointed Medical Officer for the Monasterboice Dispensary, vice Keelan, resigned.

Roper, A. C., M.R.C.S.E., has been elected Surgeon to the Exeter Lying-in Charity, vice C. H. Roper, deceased.

Simpson, A., M.A., M.B., C.M., has been appointed Police Surgeon to the Burgh of Perth, at a salary of £25 per annum; and also Medical Officer of Health, with charge of Small-pox Hospital, at a salary of £50 per annum.

Streatfield, J. F., F.R.C.S.E., has been appointed Senior Ophthalmic Surgeon to University College Hospital, vice Wharton Jones, resigned.

Thistle, F. T., L.R.C.P.L., M.R.C.S.E., has been appointed Junior House-Surgeon to the Torbay Hospital and Provident Dispensary, Torquay.

Whetford, J. H., L.D.S. R.C.S.E. (of Seaside-road, Eastbourne), has been appointed Honorary Dental Surgeon to All Saints' Convalescent Hospital, and also to the Provident Dispensary.

Medical Diary for the ensuing Week.

Monday, June 27.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

St. Mark's Hospital.—Operations, 2 p.m.; on Tuesday, 9 a.m.

Tuesday, June 28.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Wednesday, June 29.

National Orthopædic Hospital.—Operations, 10 a.m.

Middlesex Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital. — Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ p.m., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ p.m.

King's College Hospital. — Operations, 2 p.m., and on Saturday at 1 p.m.

London Hospital.—Operations, 2 p.m., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 p.m.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Poor-law Medical Officers and their Remuneration.

We thank our correspondent from Yorkshire for his communication on this subject, but feel that no observations of ours at the present time would aid him in the least degree. So long as guardians act within their legal rights, and medical men are to be found who will accept salaries which make no pretence of paying profitably a man for the duties he is required to perform; so long, moreover, as medical men can be tempted to contend for unremunerative posts by problematical prospects of other future equally unremunerative appointments dangled before their eyes, as in this case; and so long, further, as both the central and local poor-law authorities approve of these appointments being dealt with on the lowest view of commercial agreement,—that is, as being worth no more than the lowest sum that a person can be induced to take them at,—the medical profession can only submit.

A. W. M.—We are well aware that emigrant ships are inspected before leaving British ports. Our remarks relate to an alleged practice of evading the regulations in force here by shipping from foreign ports under other regulations.

CONCURRENT VARIOLA AND VACCINIA.

To the Editor of THE LANCET.

Sir,—May I be permitted to point out to "In Perplexity" that "invasion" is not merely "coincident with constitutional symptoms," but includes them; for it was used by me to designate that period of marked constitutional symptoms which generally begins three days before the eruption appears.

If there were constitutional symptoms during the preceding incubation period, it was so much the better for my argument; but as I had no knowledge of their existence in O. H.'s case, I said nothing about them.

My contention was, that although the variola had the start of the vaccinia, the latter would probably modify the former at a later stage; and the further history has now shown this to have been the case.

As to the other cases of confluent small-pox showing the same "quick abatement," if we believe that the protective power of vaccinia is diminished by time, we must expect to find patients protected to very various extents by previous vaccination; and I would suggest that patients may possibly now and again be met with who are protected to about the same degree by the declining power of a long previous vaccination, as O. H. was, by the rising power of a vaccination which was performed too late to be completely protective.

I am, Sir, yours truly,
M. B.

Torquay, June 13th, 1881.

Orders for Medical Relief.

Mr. Eustace Firth.—The conditions are not parallel. Accidents are not to be foreseen; confinements may be, and an "order" should in every instance be procured and presented. It is nothing to the point that the patient is on the medical-list, because the guardians may see fit to give her an order for this means of assistance, but may, for sufficient reasons, decline to provide for her attendance during her confinement. For example, she may be referred to her own parish.

Mr. James J. Woodford is thanked for his communication, though we regret that we shall not be able to insert extracts of sermons as we did last year.

THE HEADS OF THE PEOPLE.

To the Editor of THE LANCET.

SIR,—If the facts put forward by Mr. W. H. Smith regarding the alleged decrease in size of the human head are reliable and the reasoning free from fallacy, the prospect would indeed be a melancholy one, for there is no psychological truth better established than, as Professor Bain has put it, "that great mental superiority is accompanied with a more than average size of brain," and, *cæteris paribus*, with a more than average size of head. I would therefore suggest, as an explanation of the hatters' statistics, these two considerations:—1. That change in the shape of hats in accordance with fashion is far more common now than it used to be; and, 2, that it is just those persons who change their hats with every passing fashion that possess heads considerably below the average size. Thus it would happen that the "average demand" is for hats of a smaller size than was formerly the case, while the average size of the human head has remained constant or even increased.

I am, Sir, yours, &c.,
W. J. COLLINS, B.Sc., M.R.C.S.

St. Bartholomew's Hospital, E.C.,
June 20th, 1881.

To the Editor of THE LANCET.

SIR,—I have made inquiries of Messrs. Lincoln and Bennett, of Sackville-street, whose books extend back for thirty years, and find that there is no difference whatever in the present average as contrasted with that of several years ago.—I am, Sir, yours obediently,

Brook-street, W., June 21st, 1881. R. S. GUTTERIDGE, M.D.

SANITARY CONDITION OF THE ISLE OF WIGHT.

To the Editor of THE LANCET.

SIR,—I have read this week your remarks upon the report of Dr. Ballard concerning the Isle of Wight, and in reference especially to the town of Ventnor. I trust that you will publish the following reply. As a journalist myself, I can feel more intimately your willingness to publish that which, as in this case, if allowed to pass unchallenged, must tend to the most serious injury and loss of a large number of persons whose very livelihood must depend upon the acceptance or rejection by the public of the statements that appeared in THE LANCET, published on the 4th of June inst. You speak of the "neglect" and "indifference" of the authorities of the town and of "bad drainage and sewerage, and a polluted water-supply," and you assume that from the time of Dr. Ballard's visit to Ventnor until now (nearly a year and a half) all has been neglected. I have this day had the report of the Sanitary Committee, copied from the minute-book of the Board, and as the most conclusive proof possible of the inaccuracy of the statements into which you have been led, inadvertently I am sure, I have confidence that you will insert this report, which tells of work that was in progress before Dr. Ballard visited Ventnor, and was entered upon the proceedings of the Local Board before his report was given to the world. As to a "polluted water-supply," no water can be purer, rising, as it does, to the chalk of the high downs. Dr. Ballard's objection made on the spot was in reference to the mode of carrying away the overflow from a tank used for supplying the higher levels, and within six hours after his objection was made the communication was severed. As to the flushing for other purposes, the estimate was made that not less than 500,000 gallons of pure water rushes through the main sewers of the town into the sea every twelve hours. Open ventilators, the full number recommended by Dr. Ballard, in addition to those already in use, were fixed last autumn. The certificates referred to in the report were instituted as a means of securing many matters of sanitary arrangement that are not provided for by the Local Government Act. I have made my remarks as brief as possible, knowing how valuable space is to you, and hope that you will be able in your next issue to find a place for them and for the report.

I remain, dear Sir, yours very faithfully,

Ventnor, June 14th, 1881. FLETCHER MOOR.

Extracts from a Report made to the Local Board of Ventnor by its Sanitary Committee, Feb. 1881.

"On account of the Board's having had the advantage of a long conference with Dr. Ballard, a medical inspector of the Local Government Board, who was engaged in making an official visit to the island, the committee feel that the sanitary work prosecuted during the year has been of unusual importance. All of these reasons have decided them to draw up and submit the following report. The meetings of the committee have been held once a week, and the members have kept themselves in constant communication with the surveyor, the medical officer of health, and the inspector of nuisances. The members have endeavoured to give their attention in four special directions—namely, to become acquainted with the sanitary state of every dwelling in the town, to examine into the water-supply, and to bring into thorough efficiency the working of the sanitary administration. . . . . With regard to the first of these, the committee congratulate the Board that during the past year the systematic house-to-house inspection has been completed. . . . . With regard to the sewerage arrangements of the town, it will be remembered that the Board was most anxious to follow the advice of Dr. Ballard in affording free and open ventilation of the main drains. This has received attention, and the number of ventilators is now sufficient to save the traps of the house-drains from any undue pressure of sewage gas. . . . . The committee have given great thought to the subject of the water-supply. The main supply is a typically pure and wholesome water, and the quantity is superabundant. The committee cordially endorse the extreme precautions taken by the Board against the most remote risk of contamination of the water by directing the overflow of the reservoir in an open stream down Grove-road. In cases where houses do not draw from the main supply, but have private sources, nearly the whole of these sources have been examined into chemically by Mr. Hehner, the public analyst for the island, and where his reports have been unfavourable, the committee have recommended the Board to order the closing of the wells. The few private sources still unreported upon are also to be shortly examined by Mr. Hehner. . . . The attention of your committee has been carefully directed to the slaughter-houses in the town, and, while many necessary arrangements have been made, your committee recommend constant supervision in every case. The committee have done their utmost to revive the sanitary administration of the town into a state of vigorous efficiency, and, by acquainting themselves with the work carried on by the several sanitary officials of the Board, and following this work up from week to week, the members believe they have accomplished much in this way. . . . . In conclusion, the committee cannot hand over their duties to their successors without a deep sense of the importance of the sanitary work of the town being carried on with continued vigour, especially so now that sanitary science is attracting so much attention in the country. They urge the Board to be rigid in exacting the thorough compliance of builders with the by-laws, convinced that this will save much labour, expense, and annoyance in the future. They recommend the continuance of reports from the officials with great regularity, even although these reports may be largely of a negative character so far as sanitary defects are concerned. Lastly, they would suggest that the Board should forward copies of this report, and the report of the medical officer of health, to Dr. Ballard as an indication of the value the Board attached to his advice, and the promptitude with which they adopted the suggestions he made.

"The reports are now complete, and every questionable well has been closed, those in gardens and stables not excepted."

ANTISEPTIC VACCINATION.

To the Editor of THE LANCET.

SIR,—Having seen several cases of erysipelatous and septicæmic inflammation following vaccination, and having myself been disabled for three days by the same, I would suggest that, following the acknowledged success of the "antiseptic system," considerable pain and inconvenience might be done away with by the use of the carbolic spray during vaccination and the hermetic covering of the wound afterwards.

I remain, Sir, yours truly,

Paulatim Club, Adelphi-terrace, W.C., E. F. GRUN,
June 12th, 1881. Dresser at the London Hospital.

Anti-Small-pox should consult the instructions to public vaccinators, as given in Seaton's "Handbook of Vaccination."

S.—The question is rather actuarial than medical.

Tyro.—Write to the secretary.

M.D.—An article by Dr. Percy Boulton, published in our columns on Oct. 16th last, will give the information required.

DR. J. H. GALTON'S CASE OF CÆSAREAN SECTION.

To the Editor of THE LANCET.

SIR,—I have just read in THE LANCET of the 4th inst. an account of a case of Cæsarean section by Dr. Galton. It seems a somewhat new thing for this very formidable operation to be at all warranted where there is no pelvic deformity. I am satisfied had I a similar case to deal with I would be able to accomplish delivery without having recourse to Cæsarean section. I should like to learn through your columns how practical men would have dealt with a similar case, at least such of them as do not consider Cæsarean section the proper treatment, and the "best means of saving a few months of painful life" in such a case.

I am, Sir, yours, &c.,

Lower James-street, W., June. 1881. A. C. TWEEDIE.

"THE PATHOLOGY OF ACUTE PERIOSTITIS."

To the Editor of THE LANCET.

SIR,—In the report of the meeting of the Medical and Chirurgical Society, published in your last issue, is an error—a slip of the pen on my own part—which I should be glad to have corrected. On p. 991, last line, the sentence "from the outer to the deeper parts" should be "from the deeper to the outer parts." In the abstract actually read before the Society words to the latter effect were contained.

I am, Sir, yours faithfully,

Chesham-street, S.W., June 22nd, 1881. C. T. DENT.

S. H. B.—Like a majority of the modern constructions placed on the text of Shakespeare, the interpretation is obviously groundless; but probably our correspondent recognises this fact, and makes the quotation humorously.

S. A.—We are continually receiving applications for advice as to the selection of medical practitioners and medical works. It is obvious it would be unjust to render the aid desired.

Dr. W. R. Smith (Cheltenham).—The paper is marked for insertion. We shall be glad to receive the sketches.

"HYPODERMIC INJECTION OF MORPHIA."

To the Editor of THE LANCET.

SIR,—In answer to your correspondent, "J.," Dr. Hughes, of Dinorwic Hospital, advises a great many remedies for the prevention of sickness after subcutaneous injection of morphia.

In Dr. Perry's wards in the Glasgow Royal Infirmary a solution of the bimeconate of morphia is used instead of the solution of muriate of morphia, and with marked effect.

Recently Dr. Perry had under his care two patients with sciatica, and to relieve pain injections had to be resorted to. When the muriate was used, sickness and vomiting resulted in both cases; when the bimeconate was injected (1-80th of a grain), pain was relieved at once, with entire absence of all disagreeable symptoms.

I am, Sir, yours faithfully,
QUINTON M'LENNAN, M.B

Glasgow Royal Infirmary, June 11th, 1881.

Reformed Spelling.—We have received several letters on the subject of this spelling, but prefer not to give place to a discussion.

The letter of *Mr. Sparks* (West Cowes) arrived too late for our present number. It will appear in our next.

M. O. H. should apply to the clerk of the Port of London Sanitary Authority.

MANAGEMENT, CONSTRUCTION, AND ARRANGEMENT OF HOSPITALS.

To the Editor of THE LANCET.

SIR,—As a very old subscriber to and correspondent of THE LANCET, I wish to be allowed to endorse the valuable suggestions of Dr. Frederic Mouat as to the management, construction, and arrangement of hospitals.

I agree with most of his remarks, but I consider he advocates and recommends too many subdivisions of management. No public institution or hospital can be efficiently and amicably conducted if committees and subcommittees are to be consulted on every point. If there is confidence in the management and in the honorary officer giving his time to superintend, committees need only meet at stated intervals to check the pecuniary management.

As to the nursing department of hospitals, the common sense of the public and supporters of hospitals will admit that nurses should be entirely under the control of the medical staff.

As an old sanitarian of forty years' standing, and having given an immensity of time to inculcate and promulgate "sanitary principles" (now becoming popular questions), as founder of the Women and Children's Hospital in Leeds in 1853, and having had the honour of reading papers on sanitary subjects before the meeting of the British Medical Association at Oxford (Mr. Simon in the chair), and before the Social Science Association Meeting in Leeds (Dr. Mouat sectional chairman), I hope there is no egotism on my part in expressing my opinion as to the value of Dr. Mouat's communication to THE LANCET.

I am, Sir, yours faithfully,
Leeds, June 14th, 1881. J. IKIN, F.R.C.S.

DIETETIC VALUES OF BEEF AND BREAD.

Ajax.—Beef of the best quality with little fat contains 74·4 per cent. of water, 20·5 albuminates, 3·5 fats, no starchy materials; bread, on the other hand, contains 40 per cent. of water, 8 albuminates, 1·5 fats, and 49·2 of starchy material. Meat, therefore, is rich in albuminates and fats, whilst bread abounds in starchy matter. In the construction of dietaries it is usual to allow one part of meat to three parts of bread.

W. S.—"Gazette Médicale de Paris," Jan. 17th, 1879.

Judex.—The advertisement is most objectionable. It may be assumed as a rule that respectable members of the profession do not advertise.

Esculapius.—The matter is too personal for discussion in our columns. Any lack of courtesy is to be regretted.

Dr. Andrews.—The announcement is an advertisement.

A Tailor has not enclosed the "pattern" to which he refers.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Restall, Birmingham; Dr. Leftwich, London; Dr. Macdonald; Mr. Smale, London; Messrs. MEDICAL SOCIETIES.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—Maxillary abscess and necrosis in childhood, 57 — Annual meeting, 216 — The Dental Register, 375—Exhibition of specimens, ib.—Dental caries, 622
CAMBRIDGE MEDICAL SOCIETY.—Thrombosis of pulmonary artery; Ruptured tendon of biceps humeri; The colourless corpuscles in leucæmia; Malformations in a fœtus, 16—Treatment of large hydatid cyst of liver, 176—Cases of diabetes treated by salicylic acid; Chemical theory of sudden death from chloroform; Disease of the skull in congenital syphilis, 215—Terebine as an application to wounds; Truss padded with india-rubber sponge; Large gall-stone, how it may have escaped from gall-bladder—Scirrhous cancer of the male breast; Eczema of the nipple, 543
CLINICAL SOCIETY.—Traumatic hydronephrosis; Myxœdema, 138—Chronic vomiting treated by koumiss; Gangrene of arm from a poisoned wound; Amputation of shoulder; Sarcoma of dura mater, encroaching on left temporo-sphenoidal lobe of brain, 296—Partial disease of the nuclei of motor roots of the fifth nerves; Quiescent scirrhus of breast; Erythema and herpes iris, 373—Fracture of spine treated with Sayre's jacket; Excision of tongue; Round-celled sarcoma of thigh treated by amputation at hip-joint; Bronzed skin without constitutional symptoms, 460 — Treatment of varix; Extirpation of larynx for malignant disease; Intra-cranial disease, involving several cranial nerves, 541 — Syphilitic psoriasis of head and neck; Arterial hæmatoma of forearm; Meningocele; Progressive painful inflammation of arteries, 661 — Cross-legged progression; Excision of the tongue, 700 — Report of the Committee on excision of the hip-joint in childhood; Aortic aneurism; Anorexia nervosa; Antiseptic osteotomy of the tibia, 826—Ununited fracture of the olecranon treated by suture of the bones; Chromidrosis; Stretching of facial nerve for spasmodic tic; Excision of breast in intractable eczema of the nipple, 913
EPIDEMIOLOGICAL SOCIETY. — On certain considerations regarding cholera and fever, more especially with reference to India and China, 334 — Influence of fairs, famines, floods, and seasons on the development and diffusion of cholera in India, 583 — Scrofula, tuberculosis, and phthisis in India, 784
HARVEIAN SOCIETY.—Election of officers and the President's address, 141—A case of temporary hemiplegia after localised convulsion; On types of imbecility, 335—Gastrostomy; On the nature of the so-called tendon reflex contractions, 584 — Naso-pharyngeal polypi; On interference with micturition the result of prostatic disease, 869
MANCHESTER MEDICAL SOCIETY.—Exhibition of cases and specimens, 702
MEDICAL OFFICERS OF HEALTH SOCIETY. — On the duties of medical officers of health in relation to the present epidemic of small-pox, 336—Distribution of diphtheria in West Sussex, 786—A study of the periods of incubation of the communicable diseases, 992
MEDICAL SOCIETY OF LONDON.—Long-standing stone in the bladder, without kidney disease; The action and use of certain remedies in phthisis and bronchitis, 15—Treatment of nævi and other diseases by ethylate of sodium, 176—Gunshot wound of brain; Treatment of suppuration in the knee-joint; Tumour of hard palate; Sarcoma of upper jaw, 253—Epithelioma of œsophagus; Atrophy of testicle following traumatic orchitis; The prospects of valvular disease of the heart, 333 — Treatment of hydrocele; Removal of tongue for cancer; Treatment of psoriasis by turpentine and by chrysophanic acid, 372—Renewal of upper part of femur after removal for necrosis; Ataxy with knee-phenomenon, 419 — Annual meeting; Diarrhœa in phthisis; Defects of Vision from railway collision, 461 — President's address; Pseudo-hypertrophic paralysis, 502 — Cases of disease of the nose; Traumatic rupture of the perineum; Endocarditis with embolism; Opaque optic nerve fibres, 543 — Pseudo-hypertrophic paralysis; The digestion of fats; Disseminated syphilitic meningitis, 582—Double facial paralysis; Cheiropompholyx; Tubercular meningitis, 620—Chancre on the lip; Evil results of partial operation in cancer of the breast; Acute prostatitis, 738 — Villous polypus of rectum; Muscular atrophy, 828
OBSTETRICAL SOCIETY.—Pygopagi twins; Eczema of the nipple in pregnancy; Follicular hypertrophy of the cervix; Induction of abortion, 15 —Exhibition of specimens; Complete extirpation of the uterus with both ovaries; Chronic complete inversion of the uterus; Double uterus; Fibroid tumours complicating delivery, 214—Deep depression in the left frontal bone; Modification of Hodge's pessary; Extra-uterine fœtation; Villous degeneration of the Endometrium, 336—On so-called "missed labour," 583—Dermoid cysts; Arrest of development of the genito-urinary tract in a female fœtus; Discussion on missed labour; Cases of imperforate vagina, 785—Case of phlegmasia dolens with lymphatic varix; Forty-three years' private midwifery practice, 915
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Hyposcleral cyclotomy; Rare form of muscular asthenopia; Ophthalmoplegia interna; Detachment of retina; Tumour involving optic chiasma; Epithelioma of orbit, 139—On the relation between optic neuritis and intra-cranial disease, 462—Optic neuritis, 620—Recovery from optic neuritis; Congenital anomaly in yellow-spot region; Blood-clot behind iris; Colour-blindness, 663 — Retinal hæmorrhages with high arterial tension; Paralysis of both third nerves, 829
PATHOLOGICAL SOCIETY. — Enlargement of median nerve; Fracture of olecranon; Diastasis of lower end of humerus; Molluscum contagiosum; Obstruction of mesenteric vessels, 56—Acute myostitis; Abscess of liver; Cirrhosis of liver and tuberculosis; Thrombosis of innominate vein; Stenosis of tricuspid orifice; Fibrocyst of uterus, 136 — President's address; Epithelioma of thigh; Strangulated hernia reduced en masse; Rupture of aorta; Recurrent sarcoma; Scleroderma; Chloasma, 212 — Congenital truncation of forearm; Tubercular disease of joints; Abscess in the liver, 293—Unilateral hypertrophy of head and face; Glioma of cord, with dilatation of central canal; Fœtal tumour; Vesical calculus in dog; Syphilitic disease of skull; Malformation of heart; Cancer of bladder; Leucoderma; Zeroderma, 418—Eczema of nipple and cancer of mamma; Cystic degeneration of breast; Cystic disease of kidneys and liver; Cystic disease of fœtal ovary; Cancer of mediastinal glands, 458 — Combined carcinoma and adeno-fibroma of the breast; Hyaline myxoma of breast; Cranium and brain from a hydrocephalic adult; Dermoid tumour of soft palate; Lupus erythematosus; Squamous epithelioma of upper jaw, 580—Cylindroma of popliteal space; Cancer of rectum; Villous polypus of bladder; Cirrhosis of liver in a child; Membranous tracheitis following tracheotomy, 699—Molluscum contagiosum; Hepatic abscess; External hydrocephalus; Sarcoma of kidney; Aneurisms of cerebral arteries; Colloid cancer involving the spleen; Spontaneous disintegration of calculi; Intussusception; Abdominal tumour, 782—Intestinal obstruction; Cerebral tumour; Calcareous plates in heart; Pylephlebitis; Filaria sanguinis hominis; Pulmonary aneurism; Cerebral aneurism; Subastragaloid dislocation of foot; Dislocation of astragalus; Genu valgum; Sarcoma of femur, 825
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—A series of 172 antiseptic abdominal sections; Radical cure of varicocele, 101—Observations on the value of stethometry in the prognosis of chest disease, 175 — The condition of large arteries after ligature under antiseptic and non-antiseptic measures; Axillary aneurism treated

by antiseptic ligature of third part of subclavian artery; Partial restoration of lumen of vessel, 251—Two hundred additional cases, completing one thousand cases of ovariotomy; Development of a layer of elastic fibres in duct cancer of the breast; Trephining in epilepsy, 332—Annual meeting; President's address, 371—A probable cause of lead colic; The ox aorta ligature and the variability of catgut, 416—Innominate aneurism treated by simultaneous distal ligature of the carotid and subclavian arteries, with remarks on the behaviour of a tendon ligature, 501—Hepatotomy; Removal of the uterine appendages, 868—Urticaria tuberosa; Treatment of simple fractures and dislocations of the bones of the leg by the immediate application of plaster-of-Paris splints; The pathology of acute periostitis; Vascular tumour of the face, 990

West Herts Medical Association.—Exhibition of specimens, 786

West Kent Medico-Chirurgical Society.—Wound in the knee-joint treated antiseptically, 57—Phimosis as a cause of hernia in infants, 141—Tumours of the abdomen simulating ovarian tumours, 177—Vascular protrusion of the eyeball; Nephrectomy by lumbar section, 659—Peculiar warty growths on the face; Experimental inquiry on artificial respiration in stillborn children, 737

Yorkshire Association of Medical Officers of Health.—Opening proceedings, 177

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Ayr County Hospital.—Surgical cases, 782
Birmingham General Hospital.—Sarcoma of right ovary; protracted metrorrhagia; removal of both ovaries; recovery, 736
Birmingham, Queen's Hospital.—Trephining for epilepsy, 989
Burton-on-Trent Infirmary.—Sarcoma of head of tibia; amputation; secondary deposit in chest; death; necropsy, 619
City of London Hospital for Diseases of the Chest.—Case of secondary intra-thoracic cancer; necropsy, 658
Clayton Hospital, Wakefield.—Glossitis, 136
Cumberland Infirmary, Carlisle.—Two cases of wound of the wrist-joint treated antiseptically, 579
Cunningham Hospital, St. Kitts, West Indies.—Case of elephantiasis of the leg; amputation; secondary hæmorrhage on the twentieth day; ligature of femoral; death, 293
East London Hospital for Children.—Cases of congenital syphilis, 173
Geneva l'Hôpital Cantonal.—Operations for the removal of the thyroid body in goitre, 953
Glasgow Royal Infirmary.—Lead poisoning, ending in convulsions and death, 331
Great Northern Hospital.—A case of telangiectasis, 135; fracture of the skull; curious muscular twitchings and spasm; death, 952
Guy's Hospital.—Surgical cases, 330—Old-standing stricture of urethra; cystitis; foreign body in bladder; external urethrotomy; suppurative peritonitis; perforation of bladder; bedsore; death, 456—Compound fracture of lower end of femur; acute gangrene, fatty embolism; death, 618—Compound comminuted fracture of leg; attempted preservation; secondary amputation; fatty organs, death, ib.—Cancer of rectum, colotomy, 1026
Kashmir Hospital.—Pulsating bronchocele; ligature of the vessels; relief, 458
King's College Hospital.—Fracture of the internal condyle of the humerus; disease of the joint; excision, 54—Two cases of obscure abdominal tumour; operation; cure, 249—sarcoma of the scapula; removal, 952—Excision of the upper end of the femur, ib.
Lincoln County Hospital.—Idiopathic anæmia treated with arsenic and dialysed iron, 14—Gunshot injury; destruction of right knee-joint and amputation of thigh; aneurism of left femoral artery treated by digital pressure and Esmarch's bandage, 292
Liverpool Northern Hospital.—Vesical calculus; lateral lithotomy; subsequent discharge of pus from umbilicus; recovery, 540
Liverpool Royal Southern Hospital.—Cases of traumatic tetanus, 249—Exostosis of the antrum; removal of superior maxilla; death, 414—Rheumatic fever with hyperpyrexia and coma; cool bath; cure, 867
London Hospital.—Hystero-epilepsy; phases like those described by Charcot; obstructive dysmenorrhœa; treatment by dilatation of cervix uteri, 369—Acute yellow atrophy of the liver; necropsy; remarks, 780—Lacerated wound of knee-joint; Listerism; recovery with movable joint, 989
Loughborough Infirmary.—Fibro-cystic tumour of the uterus; operation; death, 212
Manchester, St. Mary's Hospital.—Paralysis of right lower extremity, following an injury to the sacral plexus during a difficult labour, 54
Manchester Royal Infirmary.—Case of hepatic abscess, 371
Middlesex Hospital.—Hysterical vomiting of eight months' duration, 291—Intra-uterine fibroid tumour, sessile; its entire discharge by exfoliation promoted by incisions of graduated depth into the growth, 866—Intra-uterine and intra-mural fibroid or myoma; removal by enucleation, ib.
Montgomeryshire Infirmary.—Case of dislocation of thigh, with persistent lengthening of limb after reduction, 501
National Hospital for the Paralysed and Epileptic.—Cases of amyotrophic lateral sclerosis, 822
Newark Hospital.—Hysterical spinal affection of two years' duration; cured by Corrigan's iron, 101
Newcastle-on-Tyne Infirmary.—Epithelioma of the uterus, 14
North Staffordshire Infirmary.—Three cases of excision of the tongue, with remarks on the various modes of removing the tongue, 911
Ross Cottage Hospital.—Loose cartilage in knee-joint; removal, 136
Royal Albert Edward Infirmary, Wigan.—Compound depressed fracture of skull; symptoms of compression; trephining; death, 211
Royal Berks Hospital, Reading.—Six cases of ovariotomy, 174
Royal London Ophthalmic Hospital.—Cases of optic neuritis and neuro-retinitis, 210; two cases of sarcoma of choroid; one of traumatic hæmorrhage into the vitreous, 697
St. Bartholomew's Hospital.—Sympathetic ptosis, probably from decayed teeth, 578—embolism of the arteria centralis retinæ, 579—ectopia centrum; iridodonesis; myopia and old choroditis, ib.
St. George's Hospital.—Case of bromide eruption, 735; two cases of cataract, 910
Shanghai General Hospital.—Multiple liver abscess in connexion with dysentery; death; remarks, 55
South Devon and East Cornwall Hospital, Plymouth.—Three cases of poisoning by the œnanthe crocata or hemlock water-dropwort, one fatal, 823
Southport Infirmary.—Fatal case of depressed fracture of skull, with slight symptoms, 250
Stockton Hospital.—Amputation below the knee in which no ligatures were required; recovery, 867—Amputation through the lower third of the thigh; death, ib.
Stratford-on-Avon Infirmary.—Smashed elbow; amputation; antiseptic absorbent pads; rapid healing, 458—Smashed hand; attempted "conservative surgery"; gangrene; reamputation, ib.
Sussex County Hospital.—Case of stricture of rectum in a boy; colotomy; relief, 659
Toxteth Workhouse Hospital, Liverpool.—Stokes's supra-condyloid amputation, 580—Internal urethrotomy, 736
University College Hospital.—Paralysis of the crico-arytenoidei postici or dilators of the glottis, 13—Paresis of the adductors of the cords, ib.—Ozæna, ib.
Victoria Dock District Dispensary.—Seven consecutive cases of pleurisy with effusion; paracentesis; remarks, 540
Wandsworth Infirmary.—Spinal caries, with suppuration not presenting externally, 1027
Western General Dispensary.—Acute rheumatism; ulcerative endocarditis; death, 781
West London Hospital.—Injury to the head; paralysis of the same side; death; sarcoma in cerebrum; remarks, 370
Westminster Hospital.—Pneumonia; extreme prostration, with loss of consciousness; crisis on the eighth day, and convalescence on the twelfth; treatment by alcohol; remarks, 99—Atony of the bladder; recovery, 414—Aneurism of ascending aorta opening into a false aneurism between the ascending aorta and sternum; apparent improvement under large doses of iodide of potassium; death, 500—Popliteal aneurism, cured by the application of Esmarch's bandage, 539—Case of intestinal obstruction; abdominal section; recovery, 988
Windsor Royal Infirmary.—Cases recently treated under a strict antiseptic plan, 619
York County Hopital.—Needle in knee; amputation; recovery, 415

REVIEWS AND NOTICES OF BOOKS.

Clinical Lectures, and Cases with Commentaries: by H. Thompson, M.D., M.A. Cantab., F.R.C.P.L., 17—The Cæsarean Section, &c.; second edition: by Thomas Radford, M.D., ib.—A Clinical Note-book for Hospital and Private Practice; fourth edition: by F. Royston Fairbank, M.D., 18—A Treatise on the Practice of Medicine: by Roberts Bartholow, M.A., M.D., LL.D., 58—A Text-book of Practical Medicine, with particular reference to Physiology and Pathological Anatomy; revised edition: by Dr. Felix von Niemeyer; translated from the Eighth German Edition by G. H. Humphreys, M.D., and Chas. E. Hackley, M.D., ib.—A Treatise on the Theory and Practice of Medicine; third edition: by John Syer Bristowe, M.D., ib.—The Science and Practice of Medicine; seventh edition: by William Aitken, M.D., F.R.S., ib.—Health Lectures, delivered in Manchester, 1878-79-80, 59.—Report on the Scientific Results of the Voyage of H.M.S. "Challenger" during 1873-76, 103, 993 — The Quarterly Journal of Microscopical Science, No. LXXXI., 141, 787—Surgical Lectures delivered at Westminster Hospital: by Richard Davy, F.R.C.S., 142—Lectures on the Surgical Disorders of the Urinary Organs. Delivered at the Liverpool Royal Infirmary; second edition: by Reginald Harrison, F.R.C.S., ib. — Transactions of the Pathological Society of London; Vol. XXXI., ib. — Peruvian Bark: by C. R. Markham, F.R.S., 177—Hernia, Strangulated and Reducible: by J. H. Warren, M.D. Boston, 179—Diseases of Women; fifth edition: by T. Gaillard Thomas, M.D., 254—Elements of Practical Medicine: by Alfred H. Carter, M.D., 255—Mittheilungen aus der Ophthalmiatrischen Klinik in Tübingen: Herausgegeben von Dr. Albrecht Nagel, 298—Handbook of Chemical Physiology and Pathology; third edition: by Victor C. Vaughan, M.D., ib.—The Journal of Anatomy and Physiology, ib., 787—The Journal of Physiology, Vol. III., No. II., 298—The Popular Science Review, No. XVII., ib.—The Plumber and Sanitary Houses: by S. S. Hellyer, ib.—Streets' Indian and Colonial Mercantile Directory for 1880-1, 299—Relapse of Typhoid Fever, especially with reference to the Temperature: by J. Pearson Irvine, M.D., F.R.C.P., 337—Pseudo-hypertrophic Muscular Paralysis: by W. R. Gowers, M.D., F.R.C.P., 338—Atlas of Pathological Anatomy: by Dr. Lancereaux and M. Lackerbauer; translated by W. S. Greenfield, M.D., 376—Fits, their Diagnosis and Immediate Treatment: by John H. Waters, M.D., ib.—Our Library Table, ib.—Disease of Liver and Portal Vein, Vol. IX., Dr. H. von Ziemssen's Cyclopædia of Medicine (English translation), 420—Conscious Matter: by W. Stuart Duncan, 421—Silverlock's Medical Reference Book: edited by George Brown, M.R.C.S., ib.—The Brain as an organ of Mind: by H. Charlton Bastian, M.D., F.R.S., 464—Atlas of Histology: by E. Klein and E. Noble Smith; Part XIII., 465—The Medical Register, 1881, ib.—Proceedings of the General Medical Council and of the Executive and Dental Committees in regard to the Registration of Dentists from Jan. 8th, 1879, to Feb. 3rd, 1881, ib.—Syphilis and Marriage: by Prof. Alfred Fournier; translated by Alfred Lingard, M.R.C.S., with Prefatory Remarks by Jonathan Hutchinson, Esq., F.R.C.S., 503—The New Playground, or Wanderings in Algeria: by Alexander A. Knox, 504—The Student's Guide to the Diseases of Women: by A. L. Galabin, M.D., 544—The Cure of Rupture, Reducible and Irreducible, also of Varicocele and Hydrocele, by New Methods: by George Heaton, M.D.; arranged and edited by J. H. Devonport, A.M., M.D., ib.—Transcendental Physics: by J. C. F. Zöllner; translated by C. C. Massey, ib.—Psychic Facts; edited by W. H. Harrison, ib. — Animal Magnetism: by Rudolf Heidenhain, M.D.; translated by L. C. Wooldridge, B.Sc., 545.—Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques; tom. XXIX., Pol—Pro, 585—Anatomy of the Arteries of the Human Body, Descriptive and Surgical: by John Hatch Power, F.R.C.S.I.; Third edition: by William Thomson, A.B., F.R.C.S., 586—L'Encéphale: Journal des Maladies Mentales et Nerveuses; Sous la Direction de MM. B. Ball et J. Luys; No. 1, ib. —Lectures on Diseases of Bones and Joints; second edition: by C. Macnamara, F.R.C.S. Eng., 623—Experimental Chemistry for Junior Students: by J. E. Reynolds, M.D., F.R.S., ib.—Lectures on Syphilis; second edition: by James R. Lane, F.R.C.S., 624 — How to use the Forceps: by H. G. Landis, M.D., 664—The Natural History of Cranes: by the late Edward Blyth, C.M.Z.S., ib.—Grundzüge der Physiologie des Menschen mit Rücksicht auf die Gesundheitspflege; fourth edition: von Prof. Johannes Ranke, 739—Dysmenorrhœa: by Heywood Smith, M.D., 740 — A Treatise on the Diseases of the Ox: by John Henry Steel, M.R.C.V.S., &c., ib. — The Journal of Anatomy and Physiology; Vol. XV., Part III., 787—Revue de Médecine, No. IV., ib.—Revue de Chirurgie, No. IV., ib.—"Brain" (April number), 788—The Cat: an Introduction to the Study of Backboned Animals, especially Mammals: by St. George Mivart, Ph.D., F.R.S., 830—Notes on Antiseptic Surgery in War: by Surgeon-Major H. Melladew, 831—A Treatise on the Materia Medica and Therapeutics of the Skin: by Henry F. Piffard, A.M., M.D., 870—Recueil des Travaux Chimiques du Dr. Domingos Freire suivi des Recherches sur la Cause, la Nature, et le Traitement de la Fièvre Jaune, par le même Auteur, 871—The Factors of the Unsound Mind: by W. A. Guy, M.B., F.R.S., 916—Index Medicus: Compiled by Dr. John S. Billings and Dr. Robert Fletcher; Vol. I., 1879; Vol. II., 1880, 917—Minor Surgical Gynæcology: by Paul F. Mundé, 954—Archives of Dermatology; edited by Dr. Bulkley; Vol. VII., No. II., ib.—The Life and Poetical Works of John Critchley Prince: by R. A. Douglas Lithgow, LL.D., M.R.C.P. Edin., F.R.S.I., &c., 955—Syllabus of Materia Medica for the Use of Students, Teachers, and Practitioners; fifth edition: by Alex. Harvey, M.D., and Alex. Dyce Davidson, M.D., 955—A Treatise on Foreign Bodies in Surgical Practice: by Alfred Poulet, M.D., 994—Neurological Contributions: by W. A. Hammond, M.D., and W. J. Morton, M.D., 1028—Medical Education and Practice in all parts of the World: by H. J. Hardwicke, M.D., 1029
